Our task is educational, and we have to encourage a love of those subjects which form the basis of the doctrine of "organic evolution," from which has arisen the greatest revolution in thought and the conduct of life the world has ever seen. How heavy the responsibility we thus incur! How poor the encouragement we, for the most part, receive at the hands of our fellow citizens! To the credit of our nation, be it said, the State is now alive to its responsibility in the matter, and to that of our County Councils, that they are doing their duty towards the higher education and science in particular. But I have grave doubts if the best is being done by private enterprise, which in all matters of progress is a characteristically British method of procedure in the higher walks of life. How many of us, competent to aid in the local management and organisation of museums and scientific institutes, are doing all that we might to keep those in charge of them on the right path. One still finds exhibited the *omnium gatherum* of scraps, the product of nature overshadowed by the artifice of man. In place of the representative collection of objects of local interest, of specimens and maps which should furnish a key to the physical constitution of the neighbourhood, and which a visitor has a right to expect on entering a strange land, one too often finds the rumble-jumble of odds and ends, with here and there a hidden treasure. There is a so-called "museum" not many miles from this place, in which payment is extracted from the visitor to behold, as a conspicuous exhibit amidst a collection of oddments, a milk tin recovered from the *Fram*, which Nansen would himself probably disown! Local control and organisation should render this sort of thing impossible, despite its being due to "private enterprise," and you must please pardon me when I draw attention to the fact that we in the south are behind our northern brethren in respect to local organisation for science and the higher education. I can conceive no better outcome of this meeting than that we should at once resolve, by connected action, to put this right.

On appeal to a frivolous public, we are told there is nothing to come of it, that work of the kind to which we aspire is not remunerative, and that the cultivation of scientific tastes is to be avoided, as narrowing in effect and tending to dwarf the religious instinct, and foster doubt. To this I would reply (1) that most of our boasted advantages in civilisation have been due to the outcome and the application of science to daily life and domestic use; (2) that there is no better tonic for the human mind than that afforded by perusal of the works of nature; (3) that the existence of matter, "motion, and law-abiding operation in nature, are greater miracles than were ever recounted by the mythologies"; and (4) that science, with love, now rules the world.

To counteract the tendency of our time, it is for us to see to it that the selection and arrangement of the exhibits in our museum collections shall furnish the visitor with a series of local object lessons, both attractive and instructive, and so ordained as to create in the mind of the mere passer-by—as can readily be done by the excellent system of descriptive labelling now coming into vogue—a desire to know more of his immediate surroundings, and, through them, of his position and relationships as a dweller in the neighbourhood and a factor in the universe at large.

The aim and object of not a few of our local scientific societies would seem to be publication rather than this, and against the tendency I would urge every influence I can command. If confined to mere local records of fact, *Proceedings* or other publications, maintained in moderation, are well and good, but, with larger and central institutions given to the meeting of persons from various localities for comparison of local forms and discussion of broad principles, the local society, in striving after this, is exceeding the bounds of reasonable distribution of labour.

Once again let me remark that we can have no higher object in view than the capture of youth. Huxley has wisely said:—

"The great end of life is not knowledge, but action. A small percentage of the population is born with special aptitude of some sort or another; and the most important object of all educational schemes is to catch these exceptional people, and turn them to account for the good of society . . . and to put them into the position in which they can do the work for which they are specially fitted."

And he added:—

"That if the nation could purchase a potential Watt, a Davy, or Faraday, at the cost of 100,000*l.* down, he would be cheap at the money."

To me nothing would be more gratifying than that there might result from this meeting an agreement upon a line of action which might track a genius and place him on the ladder he was born to ascend, to the permanent glory of his race and benefit of the world at large.

In these days, when bombast and self-assertiveness are apt to be mistaken for executive power, we want all the originality we can secure. Learning is but our knowledge of the experience of others, knowledge our very own! Higher ambition than that of adding to the sum of knowledge no man can have; wealth, influence, position, all fade before it, but we must die for it if our work is to live after us.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

A COURSE of lectures and demonstrations in practical hygiene for teachers will be held partly at Bedford College and partly at the Sanitary Institute, on Saturday mornings during the three terms of the present year.

WE learn from *Science* that Mr. John D. Rockefeller has made a further gift of 1,500,000 dollars to the University of Chicago. Of this sum, 1,000,000 dollars is to be used as an endowment fund. The balance of the gift is to be used for general needs. Mr. Rockefeller suggests that 100,000 dollars be used for the construction of a university press building. Mr. Leon Mandel has given 25,000 dollars to the University, in addition to his previous gifts.

ONE of the most important developments recorded in the recent report of the Somerset County Education Committee is the presentation, by Lord Portman, of an experimental farm, five miles from Taunton. The farm consists of 142 acres, of which 80 are pasture. Lord Portman has made considerable alterations and additions to the farm buildings in order to bring them up to date and to adapt them to the requirements of the County Committee. The primary object of the farm will be experiments on the profitable feeding of farm animals of various

kinds. Incidentally there will be considerable opportunity for experiments in the improvement of land and the best methods of growing various crops.

ANNOUNCEMENT is made in the *British Medical Journal* that the rich family of Mitsui of Tokio has offered an extensive site in that city for the erection of a University for women, and three other citizens have between them contributed a sum of 24,000*l.* for the cost of the necessary buildings. The work is already in progress, and it is hoped that the new University will be opened in the spring of 1901. It is not likely that there will be any want of students, as in recent years very many young ladies of good family have applied to be admitted to the University courses, especially to the faculty of medicine and the Polytechnic School. The latter institution is intended for the training of civil engineers, a circumstance which seems to show that Japan is about to set an example to Europe in opening up a new sphere of labour for the women of the future.

THE new Calendar of University College, London, announces several developments for the present year. There will be a course of work in experimental psychology, and an elementary course of physiological demonstrations on the nervous system and the sense-organs. A complete installation for the production of liquid air has recently been presented to the College, and facilities are offered for research at low temperatures. Instruction is given in spectroscopy, which forms a subdepartment to chemistry, and is equipped for practical work in spectrum analysis and spectrum photography. A special course on the morphology of the Sporangium has been arranged, and subdepartments in physiological chemistry and histology have been established. The Calendar contains an important speech delivered by Lord Reay, president of the College, on the development of the University of London ; and lists of original publications by members of the Faculties of Arts, Laws and of Science.

SCIENTIFIC SERIAL.

American Journal of Science, December, 1900.—Torsional magneto-striction in strong transverse fields, by C. Barus. The effect of longitudinal magnetisation is an increment of rigidity in all paramagnetic metals, whereas the permanent effect of a transverse or a circular field is relatively inappreciable so far as rigidity is concerned.—Notes on tellurides from Colorado, by C. Palache. The minerals described include sylvanite from Cripple Creek and two well-developed Hessite crystals from Boulder County.—New species of *Merycochoerus* in Montana, by Earl Douglass. The new species is called *Merycochoerus laticeps*. It has a low skull, broad behind the orbits, and narrowing rapidly towards the front and back. Brain case short, the length behind the post-frontal process being about one-half the distance in front of it. Premaxillaries united in front, forming a trough-shaped depression, evidently for the accommodation of a proboscis. Maxillaries deeply concave on the sides of the face. This, with the malo-maxillary ridge, which widens outward rapidly towards the zygomatic arch, forms a broad and nearly horizontal shelf above the posterior premolars and anterior molars.—Mohawkite, stibio-domeykite, domeykite, algodonite, and some artificial copper arsenides, by G. A. Koenig. In the Keeweenaw copper formation, the arsenides are not found in the bedded deposits of native copper, but always in fissures, intersecting the beds. The veins have thus far only been observed in the lower beds, near the foot of the formation to the southeast. Arsenic, however, is found in the smelted and refined copper of all the mines. The author describes the physical and chemical constitution of the minerals named.—Heat of solution of resorcinol in ethyl alcohol, by C. L. Speyers and C. R. Rosell. Since heat is rejected when resorcinol dissolves in a large excess of ethyl alcohol, and since heat is absorbed when it dissolves in a small quantity, the temperature should not change when these substances are mixed in some certain proportion. This proportion is found to be about six grammes of resorcinol to about 100 grams of ethyl alcohol.—The sulphocyanides of copper and silver in gravimetric analysis, by R. G. van Name. The estimation of sulphocyanides by precipitation with silver nitrate and direct weighing of the precipitate is wholly permissible. The method is extremely simple, and the results are quite accurate.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, December 6, 1900.—"On the 'Blaze Currents' of the Frog's Eyeball." By Dr. A. D. Waller, F.R.S.

The author demonstrated by experiment on the frog's eyeball the responses to electrical stimuli, which he terms "blaze currents." He gave an account of his work, which is briefly summarised in the following statements. The normal electrical response to light and to every kind of stimuli is positive, *i.e.*, from fundus to cornea ; it is partly retinal, partly by other tissues, it is reversed by pressure. "Blaze currents" are responses to electrical stimuli, and are comparable with the normal discharge of an electrical organ amounting to 0·03 volt. "Blaze currents" manifest summation of stimuli and effects, staircase increase and fatigue decline. The energy of a blaze effect may considerably exceed the energy of the exciting cause. An eyeball will show blaze currents during five days after excision, they diminish under prolonged illumination, and increase under prolonged darkness. The influence of increased temperature and pressure is studied, and under the latter four types of response are recorded.

If single electrical currents are passed through a normal eyeball and a galvanometer in a homodrome and in a heterodrome direction, *i.e.*, with and against the direction of normal discharge, the homodrome (positive) deflection is greater than the heterodrome (negative) deflection.

EDINBURGH.

Royal Society, December 3, 1900.—The Rev. Prof. Duns in the chair.—Dr. R. J. A. Berry read a paper on the true cæcal apex, or the vermiform appendix—its minute and comparative anatomy. The object of the microscopical investigation was to see what, if any, analogies exist between the true apex of the cæcum in the lower animals and its equivalent, the vermiform appendage, in man. Three types were selected, the rabbit, the cat and the pigeon ; and in these there is a marked accumulation of lymphoid tissue at the true cæcal apex, the accumulation reaching its maximum development within a week after birth. These developments were illustrated by numerous lantern slides ; and from them, combined with a comparison of the corresponding arrangements in other animals, it was concluded that lymphoid tissue is the characteristic feature of the cæcal apex, the vermiform appendix in man being represented in the vertebrate kingdom by a mass of lymphoid tissue, situated most frequently at the cæcal apex ; that, as the vertebral scale is ascended, this lymphoid tissue tends to be collected into a specially differentiated portion of the intestinal canal—the vermiform appendix ; and that this appendix in man is not, therefore, a vestigial structure, but is a specialised part of the alimentary canal. Dr. Thomas Muir communicated two papers, (1) Some identities connected with alternates and with elliptic functions ; (2) A peculiar set of linear equations, the latter being an interesting case of bi-rational transformation.

Dec. 17.—Lord Kelvin, President, in the chair.—The chairman made a communication on the transmission of force, the main conclusions being that the æther itself could not be subject to gravitation, the supposition involving instability, and that although electric and magnetic force could be explained mechanically in terms of points which acted as sources and sinks of æther flow, no explanation had hitherto been given of gravitational force. We seemed to be compelled to fall back upon the simple assumption that gravitational action was an inseparable attribute of the atoms of matter, that it was a fundamental fact behind which it was impossible to get. Mr. C. Tweedie, M.A., in a note on Dr. Muir's paper on a peculiar set of linear equations, read at last meeting, gave a simpler demonstration of a general theorem suggested in that paper. Prof. J. T. Morrison (Stellenbosch) communicated a paper (date Nov. 6) on a suggested solar oscillation, with some of its possible astronomical and meteorological consequences ; together with a generalisation as to the constitution of matter and the cause of gravitation. The sun was supposed to be subject to a pulsation of twenty-two years' period with reference to an axis nearly coincident with the axis of rotation ; and on this assumption, for which cosmical causes might be plausibly suggested, the sun-spots occurring in the regions of greatest surface displacement received a ready explanation. Variations of temperature accompanying the expansion and contraction of the sun would produce a corresponding periodicity in the vertical projection of

material from the sun, giving rise to the streamers. These, acting on the lighter materials of approaching and receding comets, would tend to form the tails pointing in the well-known manner. Electrons would be projected in great quantity along with the streamers, and would, when they reached the earth, have obvious effects upon terrestrial magnetism. These effects would occur about a year after the outburst on the sun which projected the electrons producing the effects. The second part of the paper was very speculative, and aimed at showing that gravitation and electric force were fundamentally the same. A fuller presentation of this theory was promised in a future paper.

PARIS.

Academy of Sciences, Dec. 31, 1900.—M. Maurice Lévy in the chair.—Revision of the arc of meridian of Quito, by General Bassot. The necessary funds having been voted by the French Government, the plan of operations proposed is sketched out, and the names of the surveying party given. It is proposed to measure about six degrees of arc, and the operations, which will be commenced about June 1901, will probably take four years. A committee of the Academy, consisting of MM. Faye, H. Poincaré, Hatt, Bassot and Lœwy, was appointed to control the operations of the mission.—Rectification of an analytical datum relating to the amount of hydrogen disengaged from granites by acids, by M. Armand Gautier. In a note previously published upon this subject, the amount of hydrogen given was too large, as it has been found that the powder was contaminated with some iron introduced accidentally during the process of powdering.—On the differentiation of the vascular tissues of the leaf and stem, by M. Gaston Bonnier. An examination of the origin of the vascular meristem in the leaf, and a comparison of its differentiation with that of the analogous tissues occurring in the stem. The paper is accompanied by eight illustrations.—M. Dedekind was elected a correspondent for the section of geometry, and Prof. Strasburger a correspondant for the section of botany, in the place of Sir Joseph Hooker, elected Foreign Associate.—Remarks by General Sebert on the report of the French Association for the Advancement of Science.—On the longitude of the moon, by M. H. Andoyer. In the development of the co-ordinates of the moon in trigonometrical series by Delaunay, the coefficients are inexact. The correct coefficients, recalculated by two independent methods, are now given.—On a new calculating circle, by M. Pierre Weiss. The circular slide rule described has a diameter of 16 cm., and possesses an accuracy of 1 in 2000. It is claimed that this instrument is simpler in working than the ordinary straight form of slide rule.—On a relation between the coefficient of expansion and the melting-point of metals, by M. Lémeray. It is shown that if the coefficients of expansion of the metals are plotted against their absolute melting-points, the points lie roughly on a rectangular hyperbola.—The constant of universal gravitation. On a cause of asymmetry in the use of the Cavendish balance, by M. Marcel Brillouin.—The direct application of a telephonic receiver to wireless telegraphy, by MM. Popoff and Ducretet. A telephonic receiver for the Hertzian waves is described and figured. By its use the relays and the striker or automatic decoherer can be dispensed with, and the sensitiveness of the instrument is greatly increased, messages sent by a small Ruhmkorff coil (4 mm. spark) being easily made out at a distance of 500 metres, the ordinary arrangement with relays giving no response under the same conditions.—On the diurnal variation of atmospheric electricity, by M. A. B. Chauveau.—On the place of indium in the classification of the elements, by MM. C. Chabrié and E. Rengade. The assumption of an atomic weight of 113 for indium, corresponding to the oxide In_2O_3, is confirmed by the preparation of well characterised alums with cæsium and rubidium. The acetonylacetonate of indium was also prepared, in the hope of determining its molecular weight by means of its vapour density, but although a well-defined crystalline acetonylacetonate was obtained, it was not volatile.—Study of uranium nitrate, by M. Œchsner de Coninck. Solubility determinations in different organic liquids.—The crystalline form of the luteocobaltic chlorsulphate and chlorseleniate, by M. T. Klobb.—On the osmosis of liquids through a membrane of pig's bladder, by M. G. Flusin. It has been shown in a previous communication that the velocity of osmosis of liquids through a membrane of vulcanised rubber varies in the same manner as the absorption capacity of the membrane for the liquids. The same relation has now been found to hold for a membrane of pig's bladder.—The anti-coagulating action of intravenal injections of the milk of one animal species upon the blood of animals of the same species, by M. L. Camus.—The cytological formula of the normal serosities of the pleura and peritoneum of the ox, by MM. J. Sabrazes and L. Muratet.—On the muscular serum, by M. Charles Richet. Muscle serum, although taken normally into the stomach as a food substance, produces strong toxic effects when injected under the skin. This effect is not produced after the serum has been coagulated by heat.—Indications of organic substances in certain mineral waters in the precipitate obtained with barium hydrate, by M. F. Garrigou.—On the common origin of the tissues of the leaf and stem in Phanerogams, by M. Léon Flot.—The presence of methyl alcohol in the fermented juices of several fruits, by M. Jules Wolff. The juices of the following fruits were examined:—black currants, prunes, mirabelle plums, cherries, pears, white and black grapes. After fermentation, the alcohol obtained was found to contain small quantities of methyl alcohol, varying from 2 per cent. for the spirit from black currants to 0·15 per cent. in that from grapes.

NEW SOUTH WALES.

Royal Society, November 7, 1900.—The President, Prof. Liversidge, F.R.S., in the chair.—Current Papers, No. 5, by H. C. Russell, C.M.G., F.R.S. This paper includes the records of 108 current papers collected during the past thirteen months. The total number of papers recorded in the whole series is now 602; these have been published in the Society's *Proceedings*. At this stage it is worth while to see what important results have been attained. Beginning, then, in the Indian Ocean, it is found that north of the Equator current papers drift to the eastward, but the number of papers found is too small to determine the rate of drift. From the Equator to latitude 10° south, current papers drift easterly on to equatorial Africa; five papers in this area made an average drift of 13·3 miles per day. Taking the next section, that is, from 10° south to 23° south, the average daily rate derived from eleven papers is 16·5 miles. From 23° south to 33° south, no papers have been found drifting westerly or easterly, except a few papers put afloat close to Australia, and they, as usual, went ashore. In the next area, *i.e.* between 33° south and 43° south, in the Indian Ocean, the current papers drift easterly, or, more accurately, east-north-east; twenty-one long distance papers in this area give an average daily drift of 7·6 miles. In the next section, *i.e.* 43° south to 50° south, twenty current papers show a daily easterly drift of 9·4 miles. Tabulating the dates at which current papers are found, it appears that the smallest number of current papers came ashore at the times of the *Equinoxes* (March and September), and the greatest number received in one month of each year is:—May 1897, ten papers; October 1898, twelve papers; August 1899, fourteen papers; and February 1900, fourteen papers.—The Sun's Motion in Space, Part i., History and Bibliography, by G. H. Knibbs. Apart from its intrinsic interest, the determination of the direction and quantity of the sun's motion in space is of importance, as the condition of further progress in developing a satisfactory system of defining the places of stars. The establishment of such fixed planes of reference as will be unaffected by the relative or absolute motions of the sun and stars, even for great periods of time, is clearly a desideratum, if not essential in any thorough scheme of analysis of such movements. The preliminary paper (Part i.) gives an account of the history and bibliography of the development of the idea of a motion of translation of the sun through space, and also of the determinations of the direction and amount of this motion, indicating briefly, at the same time, the general principles underlying those determinations. The conception of an indefinitely extended stellar universe, in which the sun and its planetary system is but a single and perhaps insignificant member, is one that the world owes to Giordano Bruno, in 1584. The part played by Bruno, Schyrleus, Fontenelle, Halley, Bradley, Wright, Kant, Mayer, Lambert, Michell and Lalande in establishing and extending the conception is indicated. The first deduction of the direction of the solar motion was made by Pierre Prévost in 1781 from twenty-six stars, the latest by Kobold from 2262 stars.—On a Eucalyptus oil containing sixty per cent. of geranyl acetate, by Henry G. Smith. In this paper the author shows that the oil of *Eucalyptus macarthuri*, known locally as Paddy's River Box, is very rich in geraniol, it containing 60 per cent. of geranyl acetate, and 10·64 per cent. of free alcohol, calculated as geraniol.

Linnean Society, Nov. 28, 1900.—Mr. Henry Deane, Vice-President, in the chair.—Notes on the botany of the interior of New

South Wales, Part ii., by R. H. Cambage. The vegetation met with in journeying from Cobar to the Bogan River above Nyngan, a distance of about 120 miles, is described, with special reference to the Eucalypts and their relation to geological formations.—On the Australian fairy-ring puff-ball (*Lycoperdon furfuraceum*, Schaeff.), by D. McAlpine. Bare circular patches met with in certain bowling-greens in the suburbs of Melbourne were found to be caused by a puff-ball which produced the appearance known as "fairy-rings." The puff-ball causing these rings is *Lycoperdon furfuraceum*, Schaeff., a fungus which has not hitherto been recorded from Australia, nor has it been found associated with "fairy-rings" in the Old World.—Studies on Australian Mollusca, Part iii., by C. Hedley.—Several molluscan genera new to Australia—*Blauneria*, *Stenothyra*, *Leuconopsis* and *Iravadia*—are here announced, all but the first-named of these being represented by new species. A new genus is erected for the reception of *Neritula lucida*, Ad. and Angas. New marine species from New South Wales, a new snail from Queensland, and records of new habitats conclude the article.—Note on an echidna with eight cervical vertebræ, by Dr. R. Broom. In a series of skeletons of echidna tabulated by McKay (*Proc.* Linn. Soc. N.S.W. (2), ix. 1894, p. 265) considerable variation in number is shown in all the groups of vertebræ with the exception of the cervicals. In the case now described, the eighth vertebra, which ought to be the first dorsal, is provided with a pair of quite rudimentary ribs, and is thus really a cervical vertebra.—On the ossification of the vertebræ in the wombat and other marsupials, by Dr. R. Broom. An examination of the mode of ossification of the vertebræ in a number of types of marsupials has revealed some interesting points. The odontoid process of the axis is ossified from a single median centre instead of from a pair as in man and probably most of the higher mammals. The 3rd-7th cervical vertebræ are ossified from three centres. The dorsal vertebræ are developed similarly to those in the higher mammals; and in the majority of marsupials the same may be said of the lumbar vertebræ. In the wombat (*Phascolomys mitchelli*), however, a remarkably interesting exceptional condition is presented. The first three lumbar vertebræ are developed from three centres as in man, but the fourth differs in having well-marked autogenous transverse processes. —Contribution to the bacterial flora of the Sydney water supply, Part ii., by R. Greig Smith. A *résumé* is given of the various methods that have been recommended for the selective examination of water and especially for the separation of *Bact. typhi* and *Bact. coli commune*.

DIARY OF SOCIETIES.

THURSDAY, JANUARY 10.

MATHEMATICAL SOCIETY, at 5.30.—On the Singularities of Quartic Curves: A. B. Basset, F.R.S.—On Streaming Motions past Cylindrical Boundaries: Prof. Love, F.R.S.—On some Cases of the Solution of $x^{p^n} \equiv 1$, mod. p: Prof. F. S. Carey.—On the Zeroes of Bessel's Functions: E. W. Barnes.—A Proof of the Third Fundamental Theorem in Lie's Theory of Continuous Groups: J. E. Campbell.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Capacity in Alternate Current Working: W. M. Mordey.—*And, if time permit*: The Use of Aluminium as an Electrical Conductor, with New Observations upon the Durability of Aluminium and other Metals under Atmospheric Exposure: John B. C. Kershaw.

FRIDAY, JANUARY 11.

ROYAL ASTRONOMICAL SOCIETY, at 8.—On Mechanically Correcting the Rotation of the Field of a Siderostat: H. H. Turner.—On a Method of Reducing Occultations of Stars by the Moon, together with the Reduction of Occultations observed on Three Occasions at the Liverpool Observatory: H. C. Plummer.—On the Accuracy of Eye Observations of Meteors, and the Determination of their Radiant Point: Bryan Cookson.—Leonids observed at Cambridge Observatory, November 13-15, 1900: J. C. W. Herschel.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Geodesy: Wilfrid Airy.

MALACOLOGICAL SOCIETY, at 8.—On the Anatomy of *Helix ampulla* of Benson and its Generic position in the Ariophantinæ: Lieut.-Colonel H. H. Godwin-Austen.—A Third Report on Japanese Helicoid Landshells: G. K. Gude.—On the Anatomy of *Buliminus djurdjurengis*, Ancey, from the Djurdjura Mountains, Kabylia: R. Murdoch.

MONDAY, JANUARY 14.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—Explorations in the Canadian Rocky Mountains: Prof. Norman Collie, F.R.S.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—The Structure of Metals: Prof. J. A. Ewing, F.R.S.

TUESDAY, JANUARY 15.

ROYAL INSTITUTION, at 3.—Practical Mechanics: Prof. J. A. Ewing, F.R.S.

ZOOLOGICAL SOCIETY, at 8.30.—Third Contribution to the Ichthyology of Lake Tanganyika: G. A. Boulenger, F.R.S.—On some New and Interesting Exotic Spiders collected by Messrs. G. A. K. Marshall and R. Shelford: Rev. O. P. Cambridge, F.R.S.—Contributions to the Anatomy of Picarian Birds. No. IV. On the Skeleton of the Ground-Hornbills, *Bucorvus abyssinicus* and *B. caffer*: F. E. Beddard, F.R.S.

INSTITUTION OF CIVIL ENGINEERS, at 8.—*Papers to be further discussed*: Glasgow Bridge: B. H. Blyth.—Railway Bridge over the Fitzroy River, at Rockhampton, Queensland: W. J. Doak.—The Niagara Falls and Clifton Steel Arch Bridge: L. L. Buck.—*Paper to be read, time permitting*: The Present Condition and Prospects of the Panama Canal Works: J. T. Ford.

ROYAL STATISTICAL SOCIETY, at 5.

WEDNESDAY, JANUARY 16.

SOCIETY OF ARTS, at 8.—Photography of Natural Colours by the McDonough-Joly Process: H. Snowden Ward.

ROYAL METEOROLOGICAL SOCIETY, at 7.45.—Annual General Meeting.—Address on the Climate of Norway and its Factors, by the President, Dr. C. Theodore Williams.

ROYAL MICROSCOPICAL SOCIETY, at 8.—Annual Meeting.—Address by the President.

ENTOMOLGICAL SOCIETY, at 8.—Annual Meeting.

THURSDAY, JANUARY 17.

ROYAL SOCIETY, at 4.30.

ROYAL INSTITUTION, at 3.—The Origin of Vertebrate Animals: Dr. Arthur Willey.

SOCIETY OF ARTS (Indian Section), at 4.30.—Metalliferous Mining in India: Dr. John W. Evans.

LINNEAN SOCIETY, at 8.—On the Affinities of *Aeluropus melanoleucus*, Prof. E. Ray Lankester, F.R.S., with a Description of the Skull and some of the Limb-bones: R. Lydekker, F.R.S.—On the Natural History and Artificial Cultivation of the Pearl Oyster: Dr. H. Lyster Jameson.

CHEMICAL SOCIETY, at 8.—The Preparation of Esters from other Esters of the same Acid: T. S. Patterson and Cyril Dickinson.—Tecomin: a Colouring Matter derived from *Bignonia tecoma*: T. H. Lee.—A New Method for the Measurement of Ionic Velocities in Aqueous Solution: B. D. Steele.—Metal-Ammonia Compounds in Aqueous Solution. II. The Absorptive Powers ef Dilute Solutions of Salts of the Alkali Metals: H. M. Dawson and J. McCrae.

FRIDAY, JANUARY 18.

ROYAL INSTITUTION, at 9.—Gases at the Beginning and End of the Century: Prof. J. Dewar, F.R.S.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—Annual General Meeting.—*Possibe* discussion upon Mr. H. A. Humphrey's paper on Power Gas and Large Gas-Engines for Central Stations.

CONTENTS.

THURSDAY, JANUARY 17, 1901.

MODERN THERMODYNAMICS.

An Outline of the Theory of Thermodynamics. By Edgar Buckingham, Ph.D. (Leipzig). Pp. xi + 205. (New York: The Macmillan Company. London: Macmillan and Co., Ltd., 1900.)

THE study of thermodynamics is customarily approached, in treatises and text-books, from a point of view to a great extent the reverse of that which is adopted in opening up the subject of dynamics. In dynamics, the usual treatment is essentially theoretical, as opposed to experimental. Newton's laws of motion are regarded as axiomatical; the second and third laws are employed to afford quantitative definitions of force and mass respectively, the parallelogram of forces is practically assumed, and all which follows is mere mathematics. It is only quite recently that the possibility of teaching dynamics from a more experimental standpoint has been seriously considered.

In thermodynamics it is usual to go to the other extreme. Temperature is defined in the first place by a common thermometer, calorimetry is treated largely in its experimental aspect, and the first law of thermodynamics thus becomes more closely associated in the reader's mind with Joule's experiments on the "mechanical equivalent of heat" than with its interpretation as affording a definition of "quantity of heat." The ordinary treatment of the mechanical equivalent of heat would, in fact, have an analogue in dynamics if we were to start with the pound weight as unit of force, and to define the constant g as the "kinetical equivalent of force."

Of recent years a great impetus has been given to the study of higher thermodynamics by the development of physical chemistry based on the theories first enunciated by Willard Gibbs. The experimental study of what at first was a purely mathematical investigation plays a part in the history of science closely analogous with the experimental verifications of Maxwell's theory by Hertz's discovery of electromagnetic waves. This new development has, to quote Mr. Buckingham's own words, caused "a considerable gap between the text-books available and the modern memoirs." Mr. Baynes's treatise, so long the favourite English introduction to thermodynamics, does not deal with thermodynamic potentials, yet it is with the study of these functions that modern thermodynamics is primarily occupied. Several subsequent attempts have been made to produce text-books on thermodynamics, but their writers have generally introduced long digressions on extraneous matter while omitting many of the most important features of the theory.

What we have been wanting was, in the first place, an application to thermodynamics of the same deductive methods that have been used in building up other connected theories, such as rational dynamics and hydrodynamics, and, in the second place, an introduction to the study of the thermodynamic potential, the conditions of thermodynamic equilibrium and stability for a generalised system the state of which is defined by any number of variables, and not merely by two of the pressure, volume temperature triad, and, lastly, an exposition of the phase rule. In compiling this book Mr. Buckingham is practically alone in the field, and the result of his efforts will greatly remove the difficulties which most students experience in acquiring a knowledge of thermodynamics.

In Chapter i. (Thermometry) the author defines equality of temperature, and enunciates the axiom of equal temperatures, according to which bodies which are of equal temperature with a third body are themselves of equal temperature. Absolute temperature cannot, of course, be defined until the second law; but in introducing the so-called "absolute gas scale," the author is careful to guard against misleading assumptions. In Chapter ii. (Calorimetry) the various heat-units are discussed, and the advantage of the dynamical unit explained. The next chapter practically defines thermodynamic systems and thermodynamic equilibrium; while in Chapter iv. we have the first law enunciated in the form of the statement that for a cyclic process the integral of $dW+dQ$ is zero. Chapters v. and vi. deal with the problem of thermochemistry and the thermal properties o fluids, so far as they can be deduced from the first law alone. A recapitulation of the first six chapters makes up the seventh.

Chapter viii. deals with the second law of thermodynamics. The author, having previously defined absolute temperature on the ideal gas scale, here expresses the efficiency of an ideal gas engine in terms of the temperatures, so defined, of the source and refrigerator. In his proof, Boyle's and Joule's laws are assumed. We do not altogether like this order of treatment. We should prefer to see the second law treated somewhat earlier and used to furnish a definition of absolute temperature the properties of gases, as affording a measure of temperature, being subsequently deduced from Boyle's and Joule's law combined with the first and second laws. This method would altogether obviate the necessity of introducing the "gas scale of temperature." Still, the author is so careful in pointing out what is assumed and what is proved in his work that his order of treatment cannot raise any serious objections.

General Equations (Chapter ix.) introduce the thermodynamic potentials. The next chapter deals with the theory of the plug experiment for determination of absolute temperature, Lord Kelvin's equation, application of the laws of thermodynamics to the E.M.F. of a galvanic cell, change of state, and change of osmotic pressure with the temperature.

In the next chapter we have a summary of the hypotheses and conditions involved in the criteria of thermodynamic equilibrium, followed, in Chapter xii., by a concise account of applications of these conditions involving the use of the thermodynamic potentials, in which Duhem's "total thermodynamic potential" and Helmholtz's "free energy" find their explanations. The book concludes with an application of the free energy principle to the galvanic cell, and a discussion on the triple point, which latter leads naturally up to the more general theorem embodied in Gibbs's phase rule. The discussion of this theorem is somewhat condensed, the author referring to the original papers for a more detailed investigation; but for the readers of a book such as the present the

brevity of the treatment is probably an advantage. A short bibliography forms a useful appendix.

As implied in the title, the author's object has been to give a general outline of the fundamental theory, and not to enter into detailed discussions of applications. The book thus deals exclusively with the theoretical, as distinct from the experimental, aspect of thermodynamics. It may with advantage be studied in conjunction with any treatise in which the theory of heat is studied from the experimental side, and a clearer understanding of the subject will be obtained than would have been the case had Mr. Buckingham written a larger volume, containing a mixture of theoretical and experimental investigations. In a subject like thermodynamics, the fundamental axioms cannot, as a rule, be verified directly by experiment, and we are compelled to use what Dr. Stoney calls the *a posteriori* method. The evidence in favour of the axioms is mainly derived from comparing the conclusions to which they lead with the results of observation. It is important in the theoretical investigation that no assumption should be made which is not expressly stated, and Mr. Buckingham appears at least to have exercised considerably more vigilance in this respect than any previous writer. We should like to see an outline of the theory of electromagnetism treated on parallel lines. Mr. Buckingham's treatise will be an indispensable addition to the library of every physicist or physical chemist, as well as of every applied mathematician who studies thermodynamics, and the author has done much to place the introductory treatment of the subject on a sound and rational basis.

AN AUTHORITATIVE TEXT-BOOK OF PHYSIOLOGY.

Text-book of Physiology. Edited by E. A. Schäfer. Vol. ii. Pp. xxiv. + 1365. (Edinburgh and London: Young J. Pentland, 1900.)

THIS volume consists of 1258 pages of text, 97 pages of indices (subjects and authors), and is illustrated by 449 woodcuts. There is no preface. The following epitome shows the subjects dealt with, their respective authors, and, in brackets, the length of each article:—"Mechanism of the Circulation of the Blood," by L. Hill (1-168); "Contraction of Cardiac Muscle," by W. H. Gaskell (169-227); "Animal Mechanics" (228-273), "Sense of Taste" (1237-1245), "Smell" (1246-1258), J. B. Haycraft; "Muscular and Nervous Mechanism" of "Respiratory Movements" (274-312), of the "Digestive" (313-337), "Urinary" (338-346) and "Generative Tracts" (347-351), E. H. Starling; "Properties of Striped Muscle" (352-450), J. Burdon Sanderson; "Nerve" (451-560), "Electrical Organs" (561-591), Francis Gotch; "Nerve Cell" (592-615), "Cerebral Cortex" (697-782), E. A. Schäfer; "Sympathetic Nervous System" (616-696), J. N. Langley; "Spinal Cord" (783-883) and "Parts of Brain below Cerebral Cortex" (884-919), "Cutaneous Sensations" (920-1001) and "Muscular Sense" (1002-1025), C. S. Sherrington; "Vision" (1026-1148), W. H. R. Rivers; "Ear" (1149-1205), "Vocal Sounds" (1206-1236), J. G. McKendrick and Albert A. Gray.

Those familiar with the modern development and advances recently made by British physiologists will see at once that the selection of authors is a guarantee of the excellence and accuracy of the subject-matter of the several essays; for they may be regarded as such, each essay containing the results of the observations to which the author has directed his particular attention.

It appears to us that Hill's article on the circulation is an excellent *résumé* of the subject, and the author acknowledges that he is greatly indebted to the perhaps not sufficiently well-known "Lehrbuch der Physiologie des Kreislaufes," by R. Tigerstedt (1893), who has recently become professor of physiology in Helsingfors. There has been incorporated all those recently discovered facts bearing on the action and distribution of vaso-motor nerves, and influence of gravity on the circulations, with which readers of the *Journal of Physiology* are familiar.

Gaskell's paper is a philosophic discussion of the many observations that have been made on the action of cardiac muscle. It is done with a master hand, and by one who has materially advanced our knowledge of the subject. Gaskell explains the beat of the heart, the sequence of its contractions, &c., without bringing in ganglion cells at all; and he sees no more reason to assign special functions to these cells than to any other of the peripheral efferent nerve cells; and we think that he makes good his case.

Starling's articles give a clear and precise account of the subjects with which they deal, but we confess that we think a short chapter on the comparative physiology of some of the subjects would have been most valuable. In discussing the influence of the higher parts of the brain on the respiratory centre, we failed to find noted the researches of Marckwald on the effect of plugging the blood-vessels of certain cerebral areas by injecting coloured fluid paraffin wax. These results point to the importance of the posterior quadrigemina and the nuclei of the sensory part of the fifth cranial nerve as important factors in the discharge of rhythmical respiratory impulses (*Zeit. für Biol.*, vol. xxvi.). The earlier observations of Marckwald are given. We are glad to see a full exposition of the work of Kronecker, Meltzer and others on swallowing of liquids.

The mechanical, thermal and chemical properties of striped muscle are exhaustively treated by Burdon Sanderson, as was to be expected from one who has devoted so much time to the study of the time relations of muscle in action, and who, by the introduction of new methods, has added materially to the apparatus by which time-problems in other tissues may be solved. The same may be said of the admirable article on "Nerve" by Gotch, while his paper on "Electrical Organs" groups up succinctly the chief facts and theories regarding these wonderful organs. As to the nature and activity of these organs, Gotch is led to the view that, as the only excitable structures there present are the nerves and their fine terminations, the organ change is closely related to the production of molecular disturbances in its contained nerves. In any case, he regards the essential primary disturbance constituting the organ shock as nervous.

In the editor's article on the "Nerve Cell" we have, as a basis, a *résumé* of the more recent advances in the minute structure of these organs. The modern "theory of isolated units," often spoken of as the "neurone theory," he regards as by no means conclusively proved. In any

case the "neuron" terminology, as introduced by Waldeyer, has taken deep root in neurology.

Langley's article on the sympathetic and allied nervous systems is a masterly summary of a subject which, by his researches, he has made peculiarly his own, and groups up in an easily accessible form the many scattered observations on this subject.

The important topic of the "Cerebral Cortex" is fully dealt with by the editor. In mentioning the old experiment of Kircher, known as the "experimentum mirabile," it is set down to "Kirscher" (p. 712). Several of the illustrations are acknowledged from the well-known work of François-Franck and Pitres. The author deprecates the use of the term "sensori-motor," as applied to denote the so-called "motor" or excitable centres in the Rolandic area, although he does not object to the term "psycho-motor" applied to them. A difficult subject is dealt with in a terse but comprehensive manner.

Sherrington's article on the spinal cord displays a mastery of his subject which at once elicits one's admiration. Necessarily, in dealing with the mass of detail many new terms have to be coined for the numerous phenomena which have been discovered in recent years. There is a due admixture of the historical with the results of recent research. What the Germans call Bell's law appears here as "Bell-Magendie law." The word "Bahnung," introduced by Exner into nerve physiology, is, we think, better rendered by "facilitation," adopted by Sherrington, than any of the other proposed equivalents we have seen.

It is evident that a large amount of industrious application has been expended by Sherrington on his articles on "Cutaneous Sensations" and on "Muscular Sense." In the former we find the recent work of Goldscheider, v. Frey and Kiesow treated with ample detail; but perhaps the article on the "muscular sense," grouping up as it does the numerous stray observations, will attract much attention. The value of Sherrington's own work on the "Muscle-spindles," which he showed degenerated after section of the posterior nerve roots outside the spinal ganglion, laid the basis of a more definite physiology regarding the important part played by certain afferent impulses from striped muscle in regulating the activities of the parts from which they proceed. Indeed, the chapter on "the peripheral apparatus of the muscular sense," though short, is an excellent *résumé* of the present knowledge of this important subject, and to which clinicians will find it profitable to devote their attention.

The essay on "Vision" is somewhat unequal, but how can it be otherwise on a subject so vast and which is treated with such wealth of detail in Hermann's "Handbuch der Physiologie."

Although necessarily there is much comparative physiology scattered throughout its pages, we could have wished to see the main facts of the comparative physiology of at least some of the subjects summarised in separate chapters. The work is one which reflects great credit on British physiologists, and we heartily congratulate the editor on its production—a work which must have entailed great labour and careful supervision. Perhaps when the next edition is called for it may be issued in three volumes, as volume ii. has reached rather bulky dimensions.

THE ROYAL OBSERVATORY, GREENWICH.

The Royal Observatory, Greenwich; its History and Work. By E. W. Maunder. Pp. 320. (London: the Religious Tract Society, 1900.)

THE history of the Royal Observatory extends over two centuries and a quarter, and its work is certainly not lacking in general interest; yet Mr. Maunder seems to be the first person to produce a popular account of them, and he has left little room for improvement to any one who comes after him in the near future. The history occupies the first 124 pages of the book in five chapters, and the description of the place as it is to-day, and the work as it is now going on, occupy the other 192 pages in eight chapters. This is probably a fair arrangement. Those who would have liked a little more of the history can find it in such works as Bailey's "Life of Flamsteed," or Rigaud's "Life of Bradley.' A "Life of Halley," on a scale worthy of him, has long been wanted, and has several times been nearly undertaken, but the project has, for one reason or another, always fallen through.

The predecessors of the present Astronomer Royal number seven: Flamsteed, Halley, Bradley, Bliss, Maskelyne, Pond, Airy. Of these Bliss only filled the position for two years; but the others lived long and worked hard at their posts, Flamsteed, Maskelyne and Airy for nearly half a century each; Halley, Bradley and Pond for nearly a quarter. And though there is so much straightforward routine work in astronomy, especially at a national observatory (and among national observatories, especially at Greenwich), yet the names of the Astronomers Royal are all associated with one or two notable events, often, though not always, special achievements of their own. The name of Flamsteed calls up at once the foundation of the observatory (which was in great measure due to him), and unfortunately also the quarrel with Newton; that of Halley, the publication of the Principia, and the first prediction of the return of a comet; that of Bradley, the discovery of Aberration and Nutation, as well as his fine catalogue of stars; that of Maskelyne, the invention of lunar distances and the chronometer, and the establishment of the *Nautical Almanac.* Airy deserves to be remembered as the man who first suggested how to compensate the compass in iron ships, though, like Flamsteed, he was unfortunate enough to leave another reputation, from his attitude towards the discovery of Neptune. Pond and Bliss are something of exceptions; but the former has recently been eulogised by Mr. Chandler as a phenomenal observer; and even of Bliss we may say that it was a distinct achievement to leave behind him only one authentic portrait, and that scratched by a boon-companion on a pewter-flagon! The seven Astronomers Royal were not only men of ability, who worked hard, but men of clear-cut individuality; and their average length of life was nearer four score years than three score years and ten. We ought to have all their portraits in our National Portrait Gallery, including an electrotype of that curiosity inscribed "This sure is Bliss, if Bliss on earth there be."

Mr. Maunder has given us the main facts of these interesting lives in a thoroughly readable form. He then passes on to the Observatory as it is now, and we must

not forget that its present size and arrangement are due, not only to the seven men mentioned above, but also to nineteen years' work from Mr. Christie, the present Astronomer Royal. In these nineteen years he has contributed to the buildings and equipment about as much as his seven predecessors together. There is a new transit-circle, which can be used on or off the meridian; the 13-inch refractor has been increased and multiplied into a 28-inch visual refractor, a 26-inch photographic refractor, and a 30-inch reflector, besides the 13-inch astrographic equatorial; and a large, commodious building has been erected, which more than doubles the space available for computing, measuring photographs, and all the miscellaneous duties of which the lay-mind has probably never imagined the existence. In this noble extension of our National Observatory, the Astronomer Royal has been generously helped by others, and especially by Sir Henry Thompson, who gave two of the large telescopes, and by Mr. Crisp, the architect of the new buildings, whose name we are sorry not to find in Mr. Maunder's book.

On one day in the year, "Visitation Day," the Observatory is devoted to visitors; and though it is not even then thrown open to the public, those with a definite interest in astronomy can generally obtain a card of admission. They find a great many things to see—those who see them for the first time find the number and variety almost bewildering; there is, in fact, the year's work of fifty busy people to look at, as well as the complicated instruments with which it was done. Things have changed somewhat, in spite of the reluctance of economical Governments, since Flamsteed was installed as Astronomer Royal in 1676 with a salary of 100*l.* a year, a "surly labourer" to help him, and no instruments! To such as are fortunate enough to be admitted on these annual occasions we can recommend the later chapters of the book for perusal both before they go and after they come away; a number of technical matters are described in a thoroughly attractive way.

Sometimes in reading a book a stray sentence or two impress the memory, though they may be only incidental to the main theme. Pond's notion of the kind of man who would make a good assistant in an observatory arrests the attention:—

"I want indefatigable, hard-working, and, above all, obedient drudges (for so I must call them, although they are drudges of a superior order), men who will be contented to pass half their day in using their hands and eyes in the mechanical act of observing, and the remainder of it in the dull process of calculation."

There is undoubtedly a vast amount of drudgery in astronomy, if people choose to so regard it. Other sciences multiply their observations ten or a hundred times; the astronomer deals in thousands and even millions. But men with the spirit of drudges, as Mr. Maunder truly remarks, cannot be trusted to do the work honourably and therefore accurately; and besides this the work is *not* drudgery. Mechanical it may be, but good men and true have found it far from dull. Did Herschel find it dull to pass the whole heavens in review star by star? Does Mr. Denning, of Bristol, find it dull to watch night after night for long hours on the chance of observing a few meteor-tracks, and that after a day's business toil? If it were drudgery they would have stopped, but Herschel went on, and Mr. Denning goes on, and these are only two random instances out of hundreds.

At the same time Pond put his finger on a real difficulty, which is just as pressing to-day, nay, far more pressing since the introduction of photography into astronomy has so enormously increased the work. How are we to get through this work? The army of astronomers is so small; it has not been recruited with sufficient rapidity to keep pace with the extension of our Empire. Pond thought of drudges, as commanders of old employed mercenaries: both found them unsatisfactory. What is the real solution? Conscription will scarcely work here. Will the volunteers solve the difficulty, or may we hope for a big reorganisation scheme?

H. H. T.

THE MANAGEMENT OF ROADS.

Road-making and Maintenance: a Practical Treatise for Engineers, Surveyors and Others. By Thomas Aitken, Ass.M.Inst.C.E. Pp. xvi + 440. With numerous plates and illustrations. (London: Charles Griffin and Co., Ltd., 1900.)

SINCE the introduction of bicycles and motor-cars the question of road maintenance has come very much to the front. It formed one of the subjects discussed in Section G at the late meeting of the British Association, and was considered of sufficient importance to warrant the appointment of a committee to inquire generally into the subject, but more especially as to the effect of the condition of the surface of roads on the tractive force required to move vehicles along them.

The author of the book under notice has given an interesting account of the history of road-making from the time of the ancient inhabitants of Peru, and of the Romans, to the days of road revival in this country, when General Wade was employed by the Government in constructing about 250 miles of roads through the Highlands of Scotland as the most effectual means of putting an end to the Rebellion of 1715.

Then followed the establishment of turnpike trusts, no less than 1100 Acts of Parliament having been passed for this purpose, and a very large amount of capital was raised for opening out new, or improving old, roads. In this work Telford, the father of modern civil engineering, constructed over 900 miles at a cost of nearly half a million of money. So great was the revolution in the condition of the roads that Macadam, another of the great road-makers, was described as being regarded by the public as a sort of magician, and his invention something preternatural. As the result of their work it became possible to run stage coaches between the principal centres of population at the rate of ten miles an hour. The establishment of railways and the termination of the turnpike trusts under provisions contained in the Acts of Parliament led to the decadence of the main roads of the country, the management of the old turnpikes having reverted to the parochial surveyors. A certain amount of improvement took place when the system of grants out of the county rates towards the maintenance of the main lines of communication was introduced, these

grants being subject to the roads being kept in repair to the satisfaction of the county justices. A further improvement took place when these roads were taken over by the County Councils.

The bicycle has, however, been the main agent in recent road improvement. To use these machines with any comfort a road must be in thoroughly good order, level, and free from loose stones and mud. The voice of the bicyclist is heard everywhere calling out when roads are in bad order, and local legislators are driven both by their own experience and that of their constituents to bring about a better condition of the main roads and highways. An institution known as the Roads Improvement Association has been formed, and, besides bringing pressure to bear on the local authorities, has issued a great quantity of literature for the guidance of local surveyors and roadmen as to the management of the roads; upwards of 13,000 pamphlets containing practical information on the management of roads have been distributed by this society.

Fortunately road reformers are able to show, by conclusive evidence, that roads kept in thoroughly good order cost less in annual maintenance than when they are left to get rutty and uneven and covered with mud or loose stones.

Mr. Aitken's book is a good practical treatise on the making and maintenance of roads. It is divided into fifteen chapters, which deal respectively with the history of road-making; traction; the construction of new roads; bridges, culverts and retaining walls; road material; quarrying; stone-breaking and haulage; road-rolling and scarifying; paved roads, including wood, asphalt, brick, and tar macadam; footways, &c.

The book deals principally with main roads and those subject to heavy traffic, which, as a rule, are now under the care of the county surveyors, who are skilled experts, and very little attention has been given to the requirements of the ordinary highways, where improvement is most required. The space devoted to quarrying, which occupies no less than sixty-seven pages, or about one-sixth of the whole book, could well have been spared, as it is rarely in these days that a surveyor has to quarry his own road material, and the space would have been better devoted to showing how ordinary highways may be maintained in good order and kept level and clean, and material placed on them when required without inconvenience to the traffic in situations where steam road-rolling is impracticable.

OUR BOOK SHELF.

Knowledge, Belief and Certitude. By F. Storrs Turner. Pp. viii + 484. (London: Swan Sonnenschein and Co., Ltd., 1900.) Price 7*s.* 6*d.* net.

MR. STORRS TURNER distinguishes knowledge from consciousness as interpretation from datum. He alleges as base of the former three certitudes, as to self, other selves and real things. He finds the sciences to involve the same pre-conditions and to take a permissibly abstract point of view—that of a fictitious independent spectator. But he holds that, therefore, the sciences are not adequate to concrete reality, while the pretension of science in general to present the whole is vain. In psychology the standpoint of the ideal spectator is inadmissible, and philosophy has failed because of the same abstraction. But among concrete ends we find our conviction as to some certain knowledge satisfied. Real knowledge belongs to the teleological sphere.

His conclusion to the failure of the speculative and the success of the purposive reason surprised Mr. Turner with the force of a revelation. The first chapters of his inquiry, which "remain substantially as they were originally written," were committed to paper years ago when "a dense fog" covered his mind. A trace of this is to be found in the attempt to maintain concurrently that the certitude of other selves is an inference of reason (p. 74), that it is plainly one with the certitude of self (p. 89), and that neither is able to come into existence apart from the other (p. 95). Mr. Turner can say within a page that "by real things we mean permanent things" (p. 80), and that "what we have is the certitude that there are a multitude of real things, some of them permanent, most of them changing" (p. 81). It will perhaps be unnecessary to say that his verbal criticism on such writers as Mr. F. H. Bradley depends for its validity on a hit or miss principle. It is a little grotesque to have estimates of Hegelian metaphysics and post-Hegelian logic from the standpoint of "reflective common-sense, aware of its limitations." Mr. Turner thinks that continuity implies indivisibility, and his verdicts on much in philosophy and science rest on similar misunderstandings.

"Knowledge, Belief and Certitude" is, however, by no means a worthless book. There is a certain dialectical ability in much of it, and a tenacity as to main principles which will appeal to the clear-headed reader who can discount the fallacious element. It is, however, as an honest attempt to think the problem of knowledge right through, and to present a record of the process as well as the results of his investigation, that it chiefly commends itself. How and why Mr. Turner came to his estimate of various views and systems, rather than that estimate itself, is the thing worth studying.

H. W. B.

Notions de Minéralogie. Par A. F. Renard et F. Stöber. II[me] Fascicule; Classification et Description des Espèces Minérales. Pp. 191 to 374. (Gand: Ad Hoste, 1900.)

THE first fascicule of this text-book, containing the general principles of mineralogy, has already been noticed. The second fascicule (pp. 191–374) is devoted to the detailed description of mineral species. A large number of species are mentioned and, consequently, the majority are only briefly treated; in its main features the book necessarily resembles other mineralogical text-books.

It seems that, by a wise provision, all candidates in natural science at the University of Gand devote one hour weekly to the study of mineralogy, and it is for these students that the book is primarily intended. From this point of view we think that, as in most text-books, more species are mentioned than is necessary; such rare minerals, for example, as chalcomenite and nitrobarite should scarcely come within the range of the elementary student, but the brief descriptions of the commoner minerals leave nothing to be desired.

There are several useful features in the book which deserve special mention. In the case of most of the minerals of commercial importance, such as mica, apatite, cassiterite, galena and sulphur, a statement is given of the annual world's yield and its approximate value.

Another important feature is a summary of the minerals of Belgium with their localities, with which the volume concludes. Such local information is extremely useful, and this is the first authentic list of Belgian minerals and localities which has been given. The list has evidently been compiled with care; special attention is

directed to those minerals which are peculiar to Belgium.

Many of the figures will disappoint the modern reader on account of the indifferent printing; but among the illustrations he will find several useful diagrams which are not the familiar figures common to all the text-books, for example, the projection which shows the migration of the indicatrix axes with change of composition in the plagioclase felspars.

The authors have succeeded in producing within a small compass a fairly comprehensive yet lucid treatise on the principles of mineralogy and the chief mineral species, which may safely be recommended to the student in England as well as in Belgium.

The Essentials of Practical Bacteriology: an Elementary Laboratory Book for Students and Practitioners. By H. J. Curtis, B.S. and M.D. Lond., F.R.C.S. (London: Longmans, Green and Co., 1900.)

THIS book consists of a series of lessons upon practical bacteriology, mainly for a course of study required for the Diploma of Public Health. Commencing with the preparation of nutrient media, it passes on to the systematic study of, first, certain typical non-pathogenic bacteria, then to the moulds, including ringworm and allied forms, the account of which is much fuller than usual, and, lastly, to the pathogenic organisms. Fermentation and the beer yeasts are referred to, the malaria parasites, the *Amoeba coli*, and the supposed cancer organisms are described, and the methods employed for the examination of air, water, &c., and for testing disinfectants are given. The practical details described seem to be fairly complete and accurate, and the book is copiously illustrated, many of the illustrations of cultures being extremely good. The *Bacillus enteritidis sporogenes* of Klein is not mentioned, though it is a capital organism for class work. The method of freeing cultures for the "Widal" reaction from clumps by filtration is attributed to Symmers, but is mentioned in Hewlett's "Manual of Bacteriology." The paraffin method of embedding described is needlessly complicated. These and a few other omissions and errors will doubtless be corrected should another edition be called for.

What is Heat? and What is Electricity? By F. Hovenden. Pp. xvi + 329. (London: Chapman and Hall, Ltd., 1900.)

MR. HOVENDEN has set himself the modest task of overthrowing, in the space of about 300 pages, all existing physical tenets, and substituting in their place a remarkable theory of his own. In this effort he has not succeeded, except, apparently, to his own complete satisfaction. In the first part of the book the author quotes freely from Maxwell and others, and endeavours to prove that their reasoning is fallacious. His arguments only show that he does not understand what he quotes, and that he has not appreciated the most elementary principles of the subject, such, for example, as the difference between mass and weight. Having, as he considers, sufficiently disposed of the views held by modern men of science, Mr. Hovenden proceeds to the elucidation of his own theory. It is impossible to regard this part of the book seriously, Mr. Hovenden's deductions from experiments being altogether too extravagantly absurd. It is interesting to note that his treatment of the subject is throughout entirely qualitative; we venture to think that in no single instance would Mr. Hovenden's explanations stand the test of quantitative examination. If modern theory is to be disproved, it will not be by such writings as this. The least one can expect of its opponents is that they should properly understand the fundamental conceptions involved, and this Mr. Hovenden cannot be said to have attempted to do.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

On a Proof of Traction-Elasticity of Liquids.

I HAVE read with much interest the note of Mr. T. J. Baker, on a surface-tension experiment (NATURE, No. 1600, June 28, 1900). The author describes, with photographic illustrations, a phenomenon at first observed by Savart (1833), and later studied by Hagen, Tyndall, J. Plateau, Boussinesq and myself, but in all these studies, as in Mr. Baker's note, no other force than surface tension is supposed to produce the different phases of the phenomenon. Therefore I resumed the subject two years ago[1] and endeavoured to explain the consecutive phases by proving that in this experiment there arises always some elasticity of traction, not only in both superficial layers, but even in the whole mass of the sheet.

For example, if the velocity of the jet is extremely high, the liquid is suddenly compressed by the shock against the disc; but on account of the perfect elasticity of the liquid, there is no sensible loss of *vis viva*, and the little expansion is performed in a very minute fraction of a second, during which the liquid is quickly projected in all directions parallel with the plane of the disc, and forms a sheet; as long as the intermolecular distances do not increase, the only retarding forces are the surface-tensions of both faces of the sheet; therefore the central part of the latter is even and transparent. But soon, by the stretching-out of the sheet, all molecules separate from each other, extremely little indeed, but enough to produce suddenly strong resistances; then each coming layer strikes against a retarded one, and so are formed circular strips from which many drops constantly part. Besides, as the elasticity cannot be the same in all points of a circular strip, some radial strips are also produced in the sheet, from whose broken edge very many little drops are continually thrown.

On diminishing the rate of outflow, the production of interior elasticity of traction becomes also smaller, and therefore the transparent portion of the sheet increases gradually; but the edge sinks slowly, and soon closes inwards and reaches the vertical piece supporting the disc. The surface-tension of both faces of the sheet is not the only force which drags in the water radially; for by the action of gravity the sheet can be compared with a membrane of india-rubber, that is to say, all portions are distended, not only in the superficial layers, but even in the interior mass.

It is easy to show that the distension of falling particles is all the greater as the velocity is smaller. Therefore the elasticity of traction produced by gravity increases in the proportion that the movement slackens.

We can now understand why the motion of the liquid in the vicinity of the summit of the closed figure becomes more and more difficult, until the figure rises above the plane of the disc, afterwards falls again and reforms a closed figure of smaller breadth.

With a still slower stream of water, the figure begins to oscillate vertically, just because the force of gravity draws it down, while the elastic force of traction pulls it up.

Ghent, January 2. G. VAN DER MENSBRUGGHE.

Mathematics and Biology.

IN the interesting address of Prof. Howes published in NATURE of December 10 occur the following words:—

"On this basis there are now being pushed forward attempts to apply statistical, experimental and mathematical tests to the study of vital phenomena. All honour to those who are making them, for it is certain there are phases of life capable of mathematical treatment, but the mystery of life can never be thus solved; and, concerning the objection to the observational method, with confirmation and generalisation, and rejection of the non-confirmable, our non-mathematical procedure is scientific. Huxley has long ago said of mathematics that what you get out of the machine depends entirely upon what you put into it."

[1] "*Sur les nombreux effets de l'élasticité des liquides*," 3me Communication (*Bull. de l'Acad. Roy. de Belgique*, 3me série, vol. xxxvi., p. 281, 1898.)

Now I think there are several points in the above sentences liable to misconstruction. Mathematics is purely a *form* of reasoning, and, as in the case of all forms of logic, it is merely an instrument, and the product depends upon the material dealt with. This may be the result of observation or of experiment, either of which may or may not be statistical in character. Prof. Howes, in contrasting "statistical, experimental and mathematical tests" with the "observational method," seems to be looking upon mathematical reasoning as something which has more relation to experiment than to observation. I fail to see why as an instrument it is less applicable to the gigantic overthrust of the geologist than to the test-piece in the laboratory, less applicable to an observation on the mottling of birds' eggs than to an experiment on the breeding of mice. It is perfectly true, as Huxley said, that what you get out of the machine depends entirely on what you put into it. Such a platitude in its right context may be a useful reminder. But *without your machine you may be able to get nothing at all out of your material;* and I venture to think that this is the case, not with a few, but with many branches of biological inquiry.

The reason thereof is easy to find. In vital phenomena we are never able to repeatedly observe or to experiment, as we can very closely do in physics, under exactly the same conditions with the same quantities of the same substances. The reader will probably interject, "No, and this is the very reason why mathematics can be applied to the one and not to the other!" On the contrary, because in biological investigation an exact A cannot be associated with an exact B, and an exact C observed (as we can do in physics), biology requires a much more refined logic, much more subtle mathematics than the simplest branches, at any rate, of physical inquiry do. There is nothing more full of pitfalls than "ordinary reasoning" applied to the problems of association. The biologist observes that *some* A is associated with B, and that *some* C is associated with B. But if he wishes to discover whether the relation between A and C is causal, he will need all the refinements of symbolic logic, a mathematical analysis, which is analogous to the geometry of hyperspace, before he can come to a definite logical conclusion on the possible relationship of A and C. He may observe as much as he will, but he will not find out whether the association is confirmable or non-confirmable without this higher logic. It is the all-pervading law of vital phenomena that no two individuals are identical among living forms, that variation exists in every organ and every character, which, so far from disqualifying biological phenomena for mathematical treatment, enforces a need for the most generalised forms of mathematical reasoning. Prof. Howes tells us that the mystery of life can never be solved by mathematical treatment. If he had said that the mystery of life cannot be solved by any treatment whatever, I should have heartily concurred with him. But if he means that observation, rather than observation plus the higher logic, is likely to discover the most comprehensive formula under which the phenomena of life can be described, then I am quite sure he is in error. Observation, for example, has collected a mass of most valuable facts during the past thirty years, but can any one by merely verbal generalising upon these facts venture to assert that evolution by natural selection is more than a probable hypothesis? The very nature of such ideas as variation, whether continuous or discontinuous, as inheritance, whether exclusive or blended, as selection, whether natural or sexual, leads us to the idea of number, of statistics, of frequency, of association, and enforces upon us an appeal to mathematical logic. If we are to feel that evolution by natural selection is as sure a formula as that of gravitation, it will be because mathematics steps in and reasons on the data provided by the Tycho Brahés and Keplers of biological observation.

Prof. Howes must not for a moment suppose I claim biology for the mathematician. I do not even want the mathematician to have a biological training, conscious as I am personally of the disadvantages of its absence. The mathematician who turns physicist is rarely so valuable a discoverer as the born and trained physicist who knows mathematics so far as he needs them. I believe the day must come when the biologist will—without being a mathematician—not hesitate to use mathematical analysis when he requires it. The increasing amount of work being turned out, both in America and Germany, by the younger biologists with a mathematical training, is a sign of the times. In England, I suppose (where, as usual, an Englishman, Mr. Francis Galton, first indicated the great possibilities of a new method), we shall be left behind, and let other nations gather the fruits of our sowing. Prof. Howes, indeed, leaves a field for mathematical investigation; but it was only a few weeks ago, at a discussion at the Royal Society, that another distinguished biologist asserted that in living forms there was no such thing as number!

Et Verbum interrogabat Vitam: Quod tibi nomen est? Et dicit ei: Legio, id est Numeri, mihi nomen est, quia multi sumus. Et deprecabatur eum multum, ne se expelleret extra regionem.

I doubt whether the demon can now be exorcised conjure *Verbum* ever so cunningly.

KARL PEARSON.

Education in Science.

SOME discussion has recently arisen as to the methods of teaching mathematics. Euclid has been condemned on the score of its advancement and its antiquity. An infusion of more modern geometry has been recommended, with corresponding arithmetic and algebra. In science, at the same time, there has been a tendency to recognise the historic method. Prof. Perry considers it unnecessary for pupils to traverse the course of their ancestors. But let us ask *why* this course has been recommended. On account of the successive growth of faculties in a historical sequence. Is this a fact or not? It is an undoubtable fact, and it is not sufficiently realised by any teachers. Prof. Perry has two saving principles, first to teach by practice, and second to satisfy the pupils' instincts. These being the same reasons which are used by advocates of historical methods secure a certain amount of agreement. We ought to arrive at the same result whether we study the natural methods of pupils, or the methods of primitive peoples. But Mr. Herbert Spencer has well pointed out somewhere that we ought not to go to the Greeks for examples of primitive peoples. They were highly and very specially developed. Hence arises a very great danger in the historic method.

With regard to practical and rational methods, it must have often been noticed by teachers that a great number of pupils have an inherent objection to carrying out rules without some kind of reason for them. It is also to be observed that a very vague, or even a verbal reason, will be more satisfactory than a real one. This is surely in accord with the studies of the history of science. Although it is somewhat misleading to reason from the experience of men of genius, it may be worth while to call to mind the intense satisfaction of Darwin with Euclid's concatenation, and the disgust of Huxley at the irrational rule and rote method of mathematics under which schoolboys grow up. It is the exceptional boy who delights in carrying out enigmatic rules, although all have a temporary taste for that work as sauce to the rest. It is treacherous to reason from one lesson of this kind to a regular course of it.

It is customary to speak of the activity, observation, ingenuity of children. But it is not found, either in the history of children or of primitive peoples, that they are capable of continued mental application, observation or contrivance. We might just as well speak of the great reasoning powers of children on account of their perpetual "why." It is also improper to underestimate the value of this tendency. By it children acquire and cement their knowledge, although a chain of real reasoning will absolutely exhaust them.

From this kind of reasoning we conclude that the time-taught method now pursued in mathematics is a reasonable one, that Euclid with the algebra and arithmetic corresponding is in the main advantageous. But why? Because it is conformable to the instincts of pupils, and also because it is historic. But is it conformable enough? Is it historic enough? I think not. Euclid was a grown man in a grown community of very special bent of mind. Where he does not agree with the reason for his inclusion in school curricula he should be neglected. But instead of supplementing him from more recent geometry, it should be from more antique writers and from study of pupils' methods.

Now we come to the bearing of this on the teaching of science. We are comparatively new at this game. We are finding that we have started in too high a key, and we are being recommended to go back. I have not yet seen a recommendation to exactly imitate the mathematical teachers, and go back to Pliny, Geber, Gilbert and Pallissy. But several have advised Boyle and Black. Along with this advice is an insistence on quantitative work from the very start. It appears to me this is a very grave mistake. The use of a rough balance and rough methods of measurement is all that should be aimed at in

school. For example, one teacher of girls proposes to show by furnace and acid that chalk gives off a definite quantity of gas. This seems to me appropriate for an advanced university student, but is not the thing for schools at all.

Experiments to show the indestructibility of matter have this advantage, that you must begin with some matter, and that you must have some appliances on both of which the inquiring mind may feed. But as to where the matter goes to is another matter, and as to what the measurements are all for, you might as well be noting them during the progress of a pantomime.

The same criticisms apply to physiology and botany. It is said we cannot properly study the stomach without a preliminary of histology. If so, they cannot be approached in schools, for histology is a late science and is vain and empty to pupils. The microbes of false ideas are thick in it. But Harvey knew no microscopical histology, and yet he was not altogether a fool. I find boys and girls of fifteen and sixteen studying the alternation of generations in a phanerogam, and not only the nutrition but the respiration of plants. Surely this is pushing on to modern methods with a vengeance. But is there anything gained in development of faculty? Can they *observe* these things, or do they trace a dim something which they are told are there, and recognise them with the wild delight of an irresponsible original researcher? It is the delight of a child who has jumped six feet high with just a little assistance. An independent mind rejects all this and begs for a little exercise in kinds of knowledge which you will find well represented in Pliny.

When we turn back to the books of study which we read as boys of fifteen and sixteen in the times when the ambition to kick a goal or vault ten feet was so strong and so easily ousted other ideas, how many very important laws we find which we then read and now for the first time *know*. I can remember the time when I tried to wake a class to the importance of Boyle and Charles's laws, and I can also remember the time when I remembered that my own old master vainly tried to wake us to it. The result in neither case was thanks, and it was the teachers who were wrong, not the pupils. We do our best, but we are vastly wrong, and we inflict many injustices by force of punishment just as in the old *régime* they broke the rulers over our fathers' shoulders in teaching them practical prosody. A little study of history will lessen this injustice.

At the same time we must distinguish essential historic progress from mere accidents of time. I should be sorry to exclude hydrogen explosions absolutely. JAMES SUTHERLAND.

Abbe's Optical Theorems.

IN the article, "Optical Science" (NATURE, p. 203), as well as in the preface to Prof. S. P. Thompson's translation of Lummer there mentioned, regret is expressed at the neglect in English text-books of Abbe's contributions to optical theory.

Will you allow me to remark that statements and proofs of Abbe's theorems will be found in §§ 205*b*–205*f* of the 1899 edition of my "Deschanel, Part iv." They occur in the chapter on "Systems of Lenses," and are based on careful study of the writings of Abbe and Czapski.

Ealing, January 9. J. D. EVERETT.

Fireball in Sunshine.

ON Sunday, January 6 last, at 0h. 52m. p.m., a brilliant fireball was seen by many observers in Scotland. The sky was clear and the sun shone brightly at the time. The meteor was observed from Whiteinch Park and Great Western Road, Glasgow, flashing across the north-western sky, and resembling a rocket with a long streaming tail. One correspondent at Glasgow says it travelled from the north-east to west, and that in colour it was like reflected sunlight. Another writer describes it as being of considerable size, "the fiery mass being as large as a bowling ball with a glowing red tail attached." At Killearn, N.B., the object passed from N.W. to W.N.W., and was about 12 degrees above the horizon at the time of its disappearance. It traversed a path of about 20 or 25 degrees, during which it fell about 5 degrees. The radiant of the meteor was probably in Auriga, Perseus, or Aries, so that it belonged to a different system from that which furnished the brilliant daylight fireball of January 9, 1900 (NATURE, January 25, 1900). W. F. DENNING.

Bristol.

Air and Disease.

IN these days of fresh-air treatment, some of your readers may be interested in a quotation from Palladius "On Husbondrie," an early fifteenth century MS. originally in Colchester Castle.

"The longe-woo," says that writer, "cometh ofte of yvel eire," *i.e.* lung-woe or consumption comes often of bad air. The whole verse describes the effects by which you may know bad air or water, and is, perhaps, worth quoting in its entirety.

> "The longe-woo cometh ofte of yvel eire,
> The stomake eke of eire is overtake,
> Take heede eke yf the dwellers in that leire
> Her wombes, sydes, reynes swell or ake,
> If langoure in thaire bledders ough' awake.
> And if thoue see the people sounde and faire,
> No doubt is in thy water nor thin aire."

Thus we are told that both lungs and stomach are affected by bad air and that, to detect bad air or water we are to see whether the inhabitants have aches in stomachs, &c.

The importance attached so early to air and water may, I think, prove worth mentioning, as it is not what most of us would expect. I came across the passage in turning over the leaves of Lodge's edition of Palladius, published by the Early English Text Society. HAROLD PICTON.

Clacton College, Clacton-on-Sea.

RECENT ADVANCES IN THE GEOLOGY OF IGNEOUS ROCKS.

THE closing years of the nineteenth century witnessed a revival of interest in the petrology of igneous rocks, which must be regarded as marking an important stage in the development of that subject. Much detailed work, especially in the laboratories of German universities, during the three or four decades preceding had already accumulated a large body of information; but that work had been confined in great measure to the strictly descriptive side of the science—in short, to what is properly described as petrography—and some of it fell rather into the domain of mineralogy and physical optics than of geology. The value of such a store of material cannot be overestimated; but any tendency which promises to shape it into a connected system must be welcomed by geologists as the breath of life animating the valley of dry bones. Such a movement is undoubtedly felt at the present time, and may perhaps be held to mark the transition in petrology from the stage of observation to that of generalisation. An igneous rock has come to be regarded, more constantly than before, not merely as a mineral-aggregate, but as the product of consolidation of a molten rock-magma; and consideration has been directed to the constitution of such magmas and the conditions governing their consolidation. Recognition of the importance of studying the mode of occurrence of igneous rocks and their relations to one another has led to a closer union of observation in the field with research in the laboratory. Much is being learnt concerning the geographical distribution of the rocks, their connection with crust-movements, and the sequence of eruption of different types at a given centre. The facts thus acquired, and especially the fertile conception of "petrographical provinces," each with its suite of igneous rocks having a community of characters which bespeaks a common origin, have confirmed the conviction that widely diverse rock-types may be evolved from a common parent-magma. Hence arises the problem, to which Brögger and others have boldly addressed themselves, of the processes by which such "differentiation" is effected and the conditions which control them. Hence, too, another problem, a corollary to the former, to frame a natural classification of igneous rocks, based on genetic principles, to supersede the provisional classifications on various artificial or Linnæan schemes which are at present current. The questions involved obviously present great difficulties, and petrologists would be the first to admit that some of

their speculations are of a crude and tentative nature. It is greatly to be desired that students of physical chemistry should turn their attention to petrology; the more so since some subjects, such as the nature of solutions and the constitution of alloys, which have recently been advanced in their hands, may be found to have important applications to the crystallisation of igneous rock-magmas.

Petrological research during the last few years serves especially to emphasise the value of comparative studies of different areas. There are large regions throughout which the igneous rocks show but relatively slight departures from one common type, while elsewhere comparatively small districts exhibit a surprising range of variation. Peculiar rock-types, supposed to be unique and to have the most narrowly restricted occurrence, have in some instances been found to recur at widely separated centres with the same associates and with like geological relations. More generally there are differences as well as resemblances, the rocks of two districts constituting two parallel suites, such that each type in the one suite has its representative in the other. Such a parallelism is that drawn by Brögger between the Monzoni and the Christiania rocks. It points clearly to two somewhat similar, but not identical, parent-magmas having undergone differentiation on similar lines. The investigations of the United States Geological Survey, and of other American geologists, afford numerous illustrations of these and other points. The intrusive masses in the High Plateaux region along the west side of the Rocky Mountains, furnishing, as Gilbert first showed, such beautiful examples of the laccolitic form, are, according to Cross, almost wholly of diorite, diorite-porphyrite, &c. The region lying along, and to the east of, the Rocky Mountains, from Montana to Texas, differing widely from the former belt in geological structure, is equally in contrast with it petrographically. The rocks here are generally richer in alkalies, and they embrace a remarkable profusion of types and varieties. Especially is this seen in the accounts given by Weed and Pirsson of the several mountain-groups of Montana. Some of the rock-types described are new and unique, such as missourite, a leucite-gabbro without felspar; but most of them compare with rocks already known from other areas, though usually presenting points of difference which may be significant. The memoir by Cross and Penrose on the Cripple Creek district, Colorado, may also be cited in the same connection. This district and some of the others alluded to are important mining centres, and it is very interesting to notice how economic geology and what may be termed pure petrology assist one another. Some of the economic questions raised, such as the source and origin of the Montana sapphires (Pirsson, *Amer. Journ. Sci.* 1897, vol. iv. p. 421), may be found to have no unimportant application to the chemistry of igneous rock-magmas.

Since it is not possible in a short article to give even a summary of the actual results of petrological work during late years, we confine ourselves to a few examples. In Britain one result of recent researches, by the Geological Survey and other workers, has been to reveal the occurrence of a number of rock-types hitherto but little known, or wholly unrecorded, in this country. Among them are rocks of the syenite and nepheline-syenite families and the related families of dyke-rocks, some closely comparable, and probably contemporaneous, with the remarkable suite of Devonian intrusions of the Christiania basin. Especially interesting is Teall's brief account of the intrusive masses of Cnoc na Sròine and its vicinity, in the western part of Sutherland. The main mass is found to consist of a quartz-syenite of the nordmarkite type, which graduates on the one hand into a granite, on the other into quartzless syenite, nepheline-syenite, and the rock formerly described under the name borolanite. The last-named rock is composed essentially of orthoclase and melanite garnet with some ægirine-augite and alteration-products of nepheline. A peculiar feature is the occurrence in it of polygonal pseudomorphs doubtless representing leucite, and the rock is practically identical with the so-called leucite-syenite of Magnet Cove in Arkansas. The associated minor intrusions—sills and dykes—are partly of dark hornblendic rocks approaching camptonite, partly of light felspathic rocks containing ægirine, and comparable in different varieties with the grorudite, lindöite, &c., of the Christiania district. The distribution and petrography of the Scottish lamprophyres and the peculiar felspathic rocks which seem to be their natural complements are as yet imperfectly known; but Flett, *Trans. Roy. Soc. Edin.* (1900) vol. xxxix., p. 865, has described from the Orkneys dykes of bostonite, camptonite, monchiquite and alnöite, and some of these types are known to be represented in various parts of the Highlands. Camptonites and augite-camptonites are described by Hill and Kynaston in Argyllshire, where they are genetically related to another remarkable rock-type, kentallenite, which in its association of alkali-felspar with olivine and augite resembles the olivine-monzonite of Predazzo. The kentallenite itself is related to, and occurs in part as a marginal facies of, the large granite and tonalite masses of the district. This is only one example of the very heterogeneous nature of the intrusions marked on the geological maps of Scotland as granite. The same variability characterises them from the Galloway "granites," recently described by Teall in a Survey Memoir, to the large intrusion of Aberdeen, where the extreme basic modifications are represented by troctolite and peridotite (bastite-serpentine). An interesting group of minor intrusions, as yet only partially described, includes the orthophyres, lamprophyres, and quartz-basalts of South Devon. Finally we may mention a unique rock described by Judd (*Trans. Roy. Irish Acad.* (1897) vol. xxxi. p. 48), and named rockallite after the the remote islet where it occurs. It is a peculiar granite-porphyry consisting of ægirine, quartz and albite; differing from Brögger's grorudite, and from other acid rocks, in its remarkable richness in iron and poverty in alumina and in the absence of potash.

One point worthy of remark is the way in which various crystalline rocks, to which more or less of obscurity has attached, are being reclaimed from the limbo of "gneisses," "granulites," &c., and recognised, some as true products from igneous fusion, others as metamorphosed sediments. A recently published memoir by Holland (*Mem. Geol. Surv. India* (1900), vol. xxviii.) establishes the igneous origin, and describes the petrographical characters, of an important group of Archæan rocks in southern India. We may note incidentally, as illustrating the increasing hold which the idea of genetic grouping is obtaining among petrologists, that the author boldly uses the name "charnockite series" for an assemblage of types ranging in composition from acid to ultrabasic. Their community of origin is attested not only by their intimate association but by remarkable points of resemblance which run through the whole series. The constant presence of hypersthene in the rocks is one characteristic, and the common acid type, to which the name charnockite is given, is in fact a hypersthene-granite. The component minerals exhibit an astonishing freshness of preservation. Since rocks generally similar have been described, under such names as pyroxene-gneiss, pyroxene-granulite, &c., as occupying very extensive areas in Peninsular India, Ceylon, and Burma, a proper appreciation of their nature and origin is a matter of considerable importance.

Microscopical research and chemical analysis, as representing, on the side of the laboratory, the groundwork of all our knowledge of rocks, must necessarily retain the important position which they occupy; and in both fields improved methods are coming into general

use, which impart increased precision to the results. Michel-Lévy's elaborate discussion of the optical properties of the felspars has greatly facilitated the discrimination of the several varieties; while among special instruments we may recall Fedorow's "universal theodolite," enabling accurate optical measurements to be made on crystals in random sections. The application of dense liquids to determine the specific gravity of minute fragments of minerals, and to obtain pure material for analysis, has been perfected, and, especially in the form of Sollas's "diffusion column," has been made both simple and convenient for use. The importance of accuracy and completeness in the chemical analysis of rocks has become more generally recognised. Many of the most valuable rock-analyses published in late years are due to the United States Geological Survey, who have realised the importance of maintaining an adequate staff of skilled chemists. One point brought out is the wide distribution in igneous rocks of small amounts of the heavy metals, and of some other elements, such as barium and strontium. Apart from its obvious application to questions concerning the origin of metalliferous deposits, information of this kind will probably be found to throw some light upon matters of more strictly petrological interest.

THE DISAPPEARANCE OF IMAGES ON PHOTOGRAPHIC PLATES.

IT is the aim of the modern astronomer to employ photography, whenever possible, in the many branches of his work, as by this means the peculiarities of the observer are eliminated and a permanent record is obtained that can be examined at leisure at any later date. In some kinds of work photography helps us in obtaining a great number of facts in a very short space of time, facts which would have taken weeks to accumulate by the old method of eye observation. Not only is the science more rapidly advanced by the greater abundance of material at hand, and therefore available for discussion, but the application of photography to astronomy has opened up so many new fields of work that the whole subject has now a far wider horizon than before.

To be able to photograph in a few hours objects which for ever will be outside the reach of the human eye, however aided, is one of the many marvels of this invaluable method.

The fine photographs obtained to-day, and so well illustrated in our books by the aid of the modern processes of reproduction, suggest the importance of recording the appearances of these celestial objects after some years have elapsed, in order to be able to note whether any changes in brightness or form are occurring. The magnificent work of the "Carte du Ciel," started by the far-seeing mind of Admiral Mouchez, is one of those schemes on a large scale for obtaining a survey of the universe at the close of the nineteenth century. The many thousands and thousands of photographic plates that will have been exposed to the sky when this plan will have been accomplished point out to us the immense importance that must be attached, not only to the "*keeping*" qualities of the film on the glass plates, but also to the retention of the *images* on these films.

Since one of the chief objects of Admiral Mouchez's plan was to hand down to posterity a chart of the celestial vault as recorded in our time, to enable those that follow us to compare with it that recorded in their time, the importance of the preservation of the photographic films, and the images impressed on them, cannot be overrated.

Most of the readers of NATURE are familiar with those beautiful photographs of long exposure of nebulæ and star clusters which we owe to the skill and patience of Dr. Isaac Roberts, and which he has given to the world in two magnificent volumes of plates. In the second of these volumes Dr. Roberts makes some very interesting and valuable remarks regarding the "fading" of some of the images on the photographic plates, and his experience shows that such disappearances of images after long intervals of time may assume very considerable proportions.

Although the period over which his experience extended only covered about ten years, this interval of time was sufficiently long to enable him to obtain some very striking facts.

The following brief summary of the two instances which he recorded in his second volume will give the reader a general quantitative idea of the disappearances of images during a short period.

A photograph of a region of the sky was taken on February 15 in 1886, and 403 star-images were counted on the negative. A re-count on May 29, 1895, found only 272 images, a loss of 131 images in about nine and three-quarter years.

Again, another photograph of identically the same region, taken on March 22, 1886, recorded 364 stars; the same plate, examined in May 1895, showed only 234.

These facts, then, indicate that, even after so short a period as ten years or so, the photographic film cannot be depended on, and that for lasting purposes recourse must be made to some means of reproducing the photographs soon after they have been obtained, the reproductions being as faithful to the originals as possible. It is generally known that, in nearly every method of reproduction, very faint details are lost in the process, but this loss could be easily recorded by noting the slight differences at the time; printed on good paper and with permanent ink, such reproductions should be lasting.

The fact that the great photographic chart of the sky is approaching completion causes one to think of the great expense that will be involved in reproducing the large number of individual plates. That many of the observatories which have taken part in this undertaking will find some difficulty in at once getting together the necessary funds is quite possible, so that a delay of a few years may be detrimental to the accuracy of the chart.

It is therefore very important that some means should be at hand to prevent the images of the fainter objects from fading quite away, or, if already disappeared, to bring them back to view.

Fortunately, the latter alternative can be accomplished by a process of manipulation which we owe to Sir William Crookes.

The completeness and success of this method will be gathered from the fact that when Sir William Crookes had "revived" one of Dr. Roberts' negatives that had entirely lost many images, the latter, on re-counting, "found that every one of the missing images had been restored to view, as distinctly, I think, as they were after the negatives were first developed."

The process by which Sir William Crookes accomplished this has been published in detail by Dr. Roberts in the *Monthly Notices* of the Royal Astronomical Society (vol. lxi., No. 1) for last November. As the description should prove of interest and service to many of our readers, the following account is appended, as described by Sir William Crookes himself in a letter to Dr. Roberts.

"(1) Soak the plate for three hours in distilled water.

(2) Prepare, in advance, two solutions A and B.

Solution A.		Solution B.	
Pyrogallic acid	1 oz.	Sodium carbonate (crystals)	12 oz.
Sodium metabisulphite	1 oz.	Sodium sulphite	4 oz.
Water	80 oz.	Water	80 oz.

"Mix equal parts of A and B, and allow the plate to soak in the mixture for ten minutes or a quarter of an hour, in the dark. Wash well.

"(3) Transfer the washed plate to a solution of three oz. of sodium hyposulphite in 20 oz. of water. Allow it to remain for half an hour, and then wash the plate in running water for three hours.

"(4) Prepare a 'clearing' solution according to the following formula:—

Alum	1 ounce
Citric acid	1 ounce
Ferrous sulphate	3 ounces
Water	20 ounces

"Allow the plate to soak in this for ten minutes, and then remove and wash in running water for six hours.

"(5) Prepare in advance two solutions, C and D.

Solution C.		Solution D.	
Ammonium sulpho-cyanide	100 gr.	Gold chloride	15 gr.
Water	100 oz.	Water	15 oz.

"For use take 1 ounce of each, and add 8 ounces of water. Soak the plate in this mixture for ten minutes, and at the end of the time remove and wash it in running water for half an hour. Transfer to a dish of distilled water, where it may remain for an hour. Finally, drain on blotting-paper, and allow to dry.

"The separate solutions, A, B, C and D, will keep for an indefinite time, and the same may be said of the clearing solution, if kept tightly corked. But when mixed together they will not keep, so fresh mixtures should be made each time.

"I have given you the full process adopted on the plates you sent me, but I think some of them may be omitted with no disadvantage. For example, I should like to try if the soaking in hyposulphite may be dispensed with. I think it can, but I only tried leaving it out on the plates you sent that had not faded.

"I always found the great secret of preventing images from fading out was to wash them very well in running water. The clearing solution allows the time of washing to be a little shortened, but not much.

"The sulphocyanide and gold solution has the property of precipitating gold on the image, and rendering it of a blacker colour and diminishing the chance of fading. I should think you will find it useful always to use the clearing solution and the sulphocyanide and gold solution in your usual process." WILLIAM J. S. LOCKYER.

VIBRATION OF GUN-BARRELS.[1]

THIS research on the vibration of gun-barrels is a continuation of former investigations on the nature of vibrations set up in a gun-barrel when fixed, with a view to discover how the *error of departure* is affected by rapid oscillations of the barrels when firmly clamped.

The authors' experiments were made on three small-bore rifles, placed at their disposal by the firm of Mauser—viz., one 8 mm. experimental rifle furnished with a wood stock, one 7 mm. Spanish model, and one trial gun 6 mm.—in all cases smokeless powder was used. In their early experiments the rifles were clamped firmly when fired, but in their recent work this method of support was abandoned, as they found that the clamping imposed restraints which altered the character of the shooting of the rifles and also their mode of vibration. This is by no means a new discovery. The late W. E. Metford, of well-known rifle repute, showed long ago (1870) that the shooting of a rifle was greatly changed when the barrel was securely clamped to a heavy mass of iron. In order to avoid this source of trouble the experimental guns were sometimes embedded in cork and sometimes suspended pendulum fashion by ropes, so that they were practically unrestrained and the condition of support approximated to the normal one, namely, the rather free support of the hands and shoulder of the marksman. The movements of the barrels were recorded by means of photography on a moving sensitive plate. Two methods were employed for firing the guns, viz., an electro-magnetic trigger-puller, and a pneumatic method in which a small piston, moving in a cylinder attached to

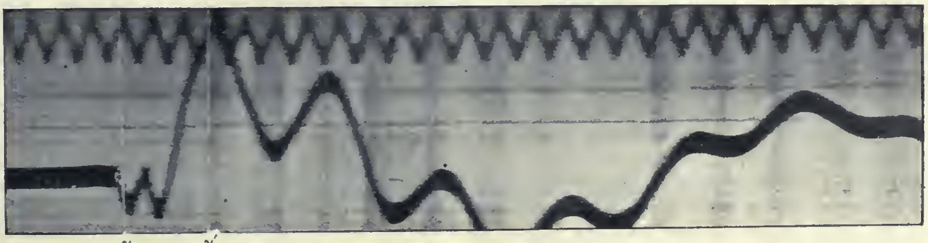

FIG. 1.—8 mm. Cal. gun clamped in cork support. Vibration curve of a point at the muzzle. γ Disengaged spark at the instant at which the shot leaves the muzzle; γ′ Disengaged spark at 4·5 m. distance from the muzzle. In the unconstrained method of holding the weapon, the amplitude of the vibration is not so strongly marked as when it is clamped. (See Fig. 2.)

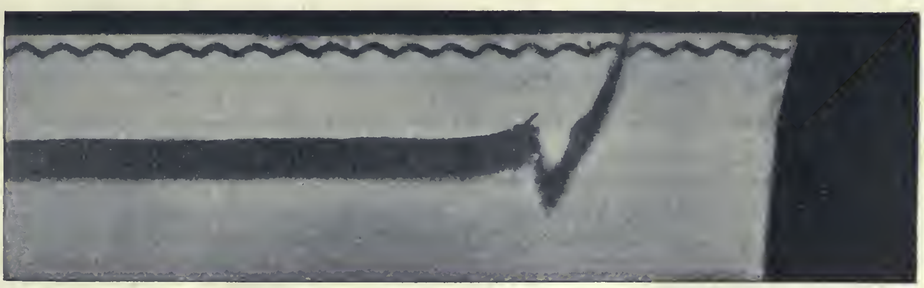

FIG. 2.—Gun 7 mm. Cal. Held by means of artificial marksman, and fired by pneumatic method.

[1] "Untersuchung über die Vibration des Gewehrlaufes." Von C. Cranz und K. R. Koch. Pp. 23; 4 plates. (München, 1900.)

the trigger-guard, moved the trigger. This pneumatic method was employed by the authors of the paper because it introduced no vibration when acting, and the method is strongly emphasised by the writers, who apparently have overlooked the fact that an exactly similar method has been in use in England for the last seven years in connection with the Tram chronograph used in ballistic work. Since the pneumatic method of firing introduces no vibration, it could be used in connection with a gun slung by ropes.

An attempt is made to show nodal points of vibration by means of sand figures, after the manner of Chladni, and sand curves were produced on a surface attached by cement to the guns when clamped and also when supported loosely, and also in the case of a barrel used without a stock. The vibrations appeared to be approximately the same in each case. The research concludes with a list of results, and it is stated that in the case of the 6 mm. gun the exit of the shot takes place just before the completion of the first quarter vibration of the first appearing second over tone. The research, although presented in a form almost too much condensed in parts to be quite clear, is of considerable interest, and has evidently been conducted with care and patience.

I wish to take this opportunity of acknowledging the kind assistance given me by Mrs. Max Schiller in connection with some portions of the authors' work on ballistics. F. J.-S.

THE ROYAL INDIAN ENGINEERING COLLEGE.

It is evident from the letters and comments which have appeared in the *Times* and other papers, that the summary notice of dismissal of a large part of the scientific staff of the Royal Indian Engineering College, Coopers Hill, is regarded as an act of injustice which, if permitted to take effect, would be distinctly detrimental to the interests of science. The facts of the case were stated in these columns last week, and an examination of them is sufficient to convince any one that the seven gentlemen who have received notice that their services will not be required after the end of the Easter term have been treated with little courtesy and no consideration. That it should be possible for men of scientific eminence to be dismissed from their posts more easily than if they were civil service messengers or clerks, is one of the many indications we have of the small value attached by the official mind to scientific work and distinction. Perhaps Lord Kelvin's letter, which we reprint below from the *Times*, will show that the matter is not to be permitted to rest in its present unsatisfactory position.

Sir,—The correspondence which appeared in the *Times* of January 3 regarding Coopers Hill College has caused a painful shock to all who know of the good work which the college has done in giving to India the benefits of well-trained engineers in the service of its Government. No one can read that correspondence, I believe, without being convinced that the seven professors and teachers whose position is threatened are justified in asking for an inquiry.

The proposed action—a sudden and arbitrary dismissal of able and distinguished scientific teachers who have been doing duty for periods of nine to thirty years in a satisfactory manner—is certainly not to be expected in institutions under the control of the British Government; and I sincerely hope that the Secretary of State for India in Council will see his way to granting the request for an inquiry.

I am your obedient servant,
Kelvin.

Netherhall, Largs, Ayrshire, January 11.

The principle of the action is as bad as the private injury, for it suggests that gentlemen of education and distinction, who have held Government posts for long periods, may have their services dispensed with at the will of a military officer having no special qualifications to enable him to know the value of their work. If there is no more security of tenure for scientific men than is implied in the act of the president of the College at Coopers Hill, it is because they have not asserted their rights with sufficient insistence, and the sooner they do so the better it will be for their positions. Opportunity for showing that the gentlemen who have been instructed to give up their appointments at Coopers Hill have the world of science behind them will be afforded by a memorial in their favour which we hear is being prepared, to be submitted to the Secretary of State for India.

No excuse worthy of consideration has been offered for the dismissal of half the educational staff of the College. The salaries of the gentlemen who have received notice —for that is what it amounts to—are by no means too liberal, so that the statement that the action has been taken with a view of reducing expenses seems altogether insufficient. As "M. A." shows in the *Times*, money is available for the needs of the College, and "it is the worst form of economy to starve the staff of a teaching institution." Another writer goes even further, for he asks, "Is it not the case that the college has been for some years self-supported by fees from students?" But, putting this question aside, we have no hesitation in saying that the work done by the gentlemen dismissed could not be carried on with the present efficiency at less cost. In any case, the method adopted is not the one best calculated to improve the efficiency of any institution.

There is one other point, and it is not the least important. Assuming that the president of the College is able to dismiss arbitrarily as many members of the staff as he cares to dispense with, then some substantial compensation should be given to those thus compulsorily retired. Dr. Johnstone Stoney mentions in the *Times* that "when, twenty-one years ago, the Government through Parliament gave Ireland an Examining Board in place of a University, it allotted when doing so the full amounts of their salaries or emoluments as compensation for loss of office to the outgoing members of the staff of the late Queen's University and to those professors of the University who were required by their statutes to discharge University as well as college duties." This principle should be brought to the front and urged upon all who have the control of institutions like that at Coopers Hill, namely, that adequate compensation for loss of office must be awarded to the members of the staff who have to retire after years of good service.

NOTES.

Sir Archibald Geikie will shortly retire from his post of Director-General of the Geological Survey of the United Kingdom. He will be entertained by his friends at a complimentary dinner early in March. All who wish to attend should communicate with Mr. F. W. Rudler, Museum of Practical Geology, 28, Jermyn Street, London, S.W.

The death is announced, at seventy-eight years of age, of Prof. Hermite, the eminent French mathematician. He was a member of the Academy of Sciences and a Foreign Member of the Royal Society. Announcement is also made of the death of M. Chatin, the botanist, and a member of the Paris Academy of Sciences.

The Geological Society will this year award its medals and funds as follows:—The Wollaston medal to Mr. Charles Barrois, of Lille; the Murchison medal to Mr. A. J. Jukes-Browne, of Torquay; the Lyell medal to Dr. R. H. Traquair, of Edinburgh; and the Bigsby medal to Mr. G. W. Lamplugh, of the Geological Survey. The Wollaston fund goes to Dr. A. W. Rowe, the Murchison fund to Mr. T. S. Hall (Melbourne), and the Lyell fund to Dr. J. W. Evans and Mr. A. McHenry.

THE Council of the Manchester Literary and Philosophical Society have awarded the Wilde Medal for 1901 to Dr. Elias Metchnikoff, of the Institut Pasteur, Paris, for his researches in comparative embryology, comparative anatomy, and the study of inflammation and phagocytosis; and the Wilde premium to Mr. Thomas Thorp, for his paper on grating films and their application to colour photography, and other communications made to the Society. The Dalton Medal for 1901 has not been awarded. The presentation of the Wilde medal and premium will take place on February 5, when Dr. Metchnikoff will deliver the Wilde Lecture on "La Flore microbienne du Corps humain."

IN connection with the dispute between the Kew Observatory and the London United Tramways Company, it was mentioned in a note in our last issue that the double trolley system was in successful operation in America. The tramways referred to are at Cincinnati, and they were originally compelled to adopt this system by the Telephone Company, which successfully opposed their allowing waste current to leak into the earth. Over two hundred miles of track are thus equipped, and the managers find, after ten years running, that the cost of maintenance is considerably reduced in consequence. This seems in itself a sufficient answer to the London United Tramways Company, who urge that it is impossible to adopt the double trolley system. It is interesting to note that the advocates of earth returns are not in agreement amongst themselves. On the one hand, the London United Tramways Company claims that there is already a potential difference between their rails and earth, greater than the maximum accepted by Kew, due to leakage currents from the Central London Railway. On the other hand, the *Electrician*, in a note in the issue of January 11, maintains that the return current in a deep level railway cannot escape from the tunnel and rise to the surface in sufficient quantity to be observable by any but a mathematician. We are afraid the engineers of the Tramways Company will not regard this as a very welcome contribution to their side of the argument.

THE twenty-eighth annual dinner of old students of the Royal School of Mines will be held at the Hotel Cecil on Wednesday, February 6. The chair will be taken by Sir G. Stokes, senior past professor of the Royal School of Mines, and Sir W. Roberts-Austen will act as vice-chairman. In view of the fact that this year is the jubilee year of the School, it is expected that a large number of old students, as well as past and present professors, will be present at the dinner.

THE president of the Röntgen Society has placed at the disposal of the Council a gold medal to be awarded to the maker of the best practical X-ray tube for both photographic and screen work. The competition is open to makers in any country. Tubes intended for competition must be sent in addressed to the Röntgen Society, 20 Hanover Square, London, W. The package should contain the full name and address of the sender, and must reach the Society not later than May 1.

THE Turin Académie royale des Sciences announces that a Prix Bressa of 9600 francs (384*l.*) is open to competition among investigators and inventors of all nationalities. The prize will be awarded to the person who, in the opinion of the Academy, made the most brilliant or useful discovery in the four years 1897–1900, or who produced the most celebrated work in pure or applied science. Works intended for consideration in connection with the prize must be sent to the President of the Academy before the end of next year. The right is reserved to award the prize to an investigator whose work is considered to be the most distinguished, even though he does not submit an account of it.

THE Rome correspondent of the *Times* states that under the auspices of the Italian Geographical Society, and in the presence of the King and Queen of Italy, the members of the Royal Family, the Diplomatic Corps, the Ministry, and an audience composed of the principal personages of Roman society, his Royal Highness the Duke of the Abruzzi delivered a lecture on Monday upon his Polar expedition, in the great hall of the Collegio Romano. Captain Cagni, who commanded the sledge party, then succeeded the Duke of the Abruzzi at the desk, and related the story of the dangers and difficulties successfully overcome in planting the Italian colours furthest north at 86° 33′ north latitude.

A ROYAL Commission has been appointed to make investigations respecting the beer-poisoning epidemic. The Commissioners are:—Lord Kelvin, Sir W. Hart Dyke, Sir W. S. Church, president of the Royal College of Physicians, Prof. T. E. Thorpe, Mr. H. Cosmo Bonsor, and Dr. B. A. Whitelegge. Dr. G. S. Buchanan, one of the medical inspectors of the Local Government Board, is the secretary to the Commission. The instructions to the Commissioners are:—To ascertain with respect to England and Wales (1) The amount of recent exceptional sickness and death attributable to poisoning by arsenic; (2) Whether such exceptional sickness and death have been due to arsenic in beer or in other articles of food or drink, and, if so, (*a*) To what extent; (*b*) By what ingredients or in what manner the arsenic was conveyed; and (*c*) In what way any such ingredients became arsenicated; and (3) If it is found that exceptional sickness and death have been due to arsenic in beer or in other articles of food or drink, by what safeguards the introduction of arsenic therein can be prevented.

IT is to the credit of the members of the medical profession at Colchester that they have decided to show how they honour the memory of Dr. William Gilbert, the famous physician to Queen Elizabeth, whose work, "De Magnete," published three hundred years ago, constitutes the bed-rock of modern knowledge of magnetism. The intention is to erect a full-length marble statue of Gilbert in a niche in the main façade of the new Town Hall at Colchester, the city in which he was born, and where his remains are buried. Already the sum of 130*l.* has been contributed by the medical men of the borough, and as the minimum amount required is only 150*l.*, it will no doubt soon be subscribed. Gilbert's work is, however, so widely known and appreciated that it is almost a pity to neglect the opportunity to make the memorial a national one. The medical men of Colchester are to be congratulated upon the initiative they have taken, but there are many other men of science who would like to see that the memorial to be erected is a worthy testimony of the regard in which Gilbert's work is held in the whole scientific world. The treasurer of the Colchester committee is Mr. Henry Laver.

A BRITISH Congress on Tuberculosis will be held in London on July 22–26, and will be opened by the Prince of Wales. There will be four sections, with presidents as follows:—I. State and Municipal, Sir Herbert Maxwell, Bart. II. Medical, including Climatology and Sanatoria, Sir R. Douglas Powell, Bart. III. Pathology, including Bacteriology, Prof. Sims Woodhead. IV. Veterinary (Tuberculosis in Animals), Sir George Brown, C.B. Every British Colony and Dependency is invited to participate by sending delegates; while the Governments of countries in Europe, Asia and America are invited to send representative men of science, and others, who will be the distinguished guests of the Congress. The information already gained, both at home and abroad, shows that consumption and other forms of tuberculosis, although preventable and controllable by intelligent precautions, still remains the direct cause of a high rate of death and sickness. In the United Kingdom

alone some 60,000 deaths are recorded annually from tuberculosis, and it is stated on good authority that at least thrice this number are constantly suffering from one form or another of the disease. The object of the forthcoming Congress is to exchange the information and experience gained throughout the world as to methods available for stamping out this disease. Papers wlll be read, and clinical and pathological demonstrations will be given; while the museum, which is to be a special feature of the Congress, will contain pathological and bacteriological collections, charts, models, and other exhibits. The address of the General Secretary of the Congress is 20, Hanover Square, London, W.

PROF. P. K. E. POTAIN, whose death we regretfully announced last week, at the age of seventy-five years, delivered his last lecture on clinical medicine at the Charity Hospital about six months ago. His treatises on diseases of the heart and lectures on clinical medicine are renowned both among physiologists and medical men. Referring to his death at the meeting of the Paris Academy of Sciences last week, M. Marey remarked that Prof. Potain developed the means of diagnosis, and showed how various sounds characteristic of diseases of the heart should be interpreted. Not only was he able to determine with precision any injury or morbid change in the exercise of functions of organs; he showed also that the disorders themselves revealed the interrelations between such functions, that, for instance, diseases of the liver and the kidney have echoes in the heart, and that pulmonary tuberculosis prevents the development of certain cardiac lesions. He was a master of clinical medicine, and an excellent physiologist, as well as a renowned physician. He devised an ingenious colorimetric method for testing certain substances, and his sphygmometei for the measurement of arterial pressure is still among the best. Prof. Potain was a member of the Paris Academy of Medicine, a member of the Academy of Sciences, and Commander of the Legion of Honour.

CUPELLATION is one of the most ancient of metallurgical processes, and was well known at least as early as the year 600 B.C. It was used by the Romans to extract silver from its ores in Spain and at Laurion, but it has been hitherto supposed that the hearths of their furnaces were made of comparatively non-absorbent materials, such as clay and marl, the litharge and other oxides being skimmed off or allowed to flow away in side channels. It is now shown, however, by Mr. Gowland, in a paper read before the Society of Antiquaries in May last, that a silver refinery was worked at Silchester in which argentiferous copper was cupelled on hearths made of bone-ash. Bone-ash has the property of absorbing molten litharge and some other oxides as readily as blotting-paper absorbs water, and apparently only its high cost prevented its use by the Romans in all their later cupellation furnaces. Careful examination of the remains found at Silchester convinced Mr. Gowland that the work there resembled some of the operations formerly practised in Japan, and that it is probable that it consisted in the recovery of the silver from Roman copper coins issued in the third century A.D. The metal contained 4 per cent. of silver, and was cupelled in three furnaces in succession with the aid of repeated additions of small quantities of lead.

DR. R. MINERVINI, of the University of Genoa, has published recently, in the *Zeitschrift für Hygiene*, the bacteriological investigations he has made of samples of air and water collected in mid-ocean during a trip from Genoa to New York and back. He finds more bacteria in air at sea than did Fischer in his classical investigations. Out of 42 determinations, however, 6 yielded no bacteria, whilst the highest number found in a volume of 27 litres of air was only 17. As was to be expected, he obtained the best results after heavy rain. No pathogenic bacteria were discovered. It is unfortunate that as regards the author's water examinations his stock of apparatus did not permit of his cultivating the samples at once after collection, but compelled him to keep them from seven to ten days until he landed. This fact deprives his quantitative results of their value. The report of the German deep-sea expedition, carried out during 1898–99, is awaited with great interest. It will be remembered that the German man-of-war *Valdivia* was placed at the disposal of the members by the Government, and it visited the African coasts as well as the Indian and Antarctic Oceans, and bacteriological investigations were included in the work of the expedition.

THE contents of the Cape *Agricultural Journal* (November 22, 1900), which has just reached us, testify to the widespread interest which is being taken in scientific agriculture in Cape Colony. Among subjects dealt with are the liming of soils, selection of seeds, merinos, rhubarb and mealie culture, "raising" calves without milk, and wide *versus* narrow waggon tires. The report for 1899 of the Colonial Bacteriologist is also inserted, and in it Dr. Edington describes a method for protective inoculation against horse-sickness, which is as follows:—Animals which have passed through an attack of the disease and have recovered are inoculated at intervals with increasing doses of virulent blood taken from affected horses. After this treatment the animals are bled and the serum preserved. Blood of the highest virulence is likewise obtained, standardised against the serum and preserved. A definite amount of the virulent blood is mixed with 50 c.c. of serum and injected subcutaneously. Some days later 30 c.c. of the same serum, with the same dose of blood, is injected. At a later date the procedure is repeated with a reduced dose of serum, and fourteen days later pure virulent blood is injected. This method is said to afford a perfect and complete solution to the problem of protecting horses which have to live in unhealthy districts in South Africa, and is very similar to that devised by the Imperial Bacteriologist of India against rinderpest, as mentioned in these notes on December 13 (p. 161).

IT is to be feared that it will be a long time before the general public realises what is desirable and what undesirable in artificial lighting. The two principal desiderata are well distributed, but not necessarily very brilliant, illumination, and cheapness, which means high efficiency and consequently high intrinsic brilliancy of the source of light: two characteristics in direct antagonism. The use of some form of diffusing shade is therefore desirable, even with the present electric lamps; and it will be essential when lamps of higher efficiency come on the market, as is sure to occur before long. Mr. W. L. Smith's experiments ("A Study of Certain Shades and Globes for Electric Lights as used in Interior Illumination," *Technology Quarterly*) are a timely and very valuable contribution to our knowledge of the relative merits of various types of shade. For a shade to be satisfactory, it should soften down and distribute evenly the light of the naked lamp, whilst, at the same time, it should not absorb too great a proportion of it. Mr. Smith's experiments show that this problem is solved by very few of the shades in ordinary use. It is worthy of remark that the author finds that the Holophane shades, in which the cutting of the glass is determined on scientific instead of artistic principles, are greatly superior to all others. We have seen a Nernst lamp (which is, with the exception of the arc, the most intense form of artificial illuminant) burning in a Holophane globe, and can fully endorse Mr. Smith's remarks on the excellent manner in which these globes soften and diffuse the light. It is to be regretted that the author has not drawn more distinction between globes designed to cover the lamp and shades merely intended to be hung over it, as direct comparison of the two classes is hardly fair.

The pamphlet, short though it is, contains many suggestive results, and we await with interest the promised account of further experiments.

IN the *Physical Review*, xi. 5, Mr. W. P. Boynton gives an investigation of the form of Gibbs' thermodynamic model for a substance following Van der Waals' equation, and compares this model with that given by Maxwell.

PROF. ANTIGONO RAGGI, writing in the *Rendiconti* del R. Istituto Lombardo, xxxiii. 17, gives a summary of the works of Serafino Biffi, who died on March 27, 1899. Biffi was the author of many valuable contributions to medical and physiological science, and we are glad to learn that his collected works are shortly to be published.

A PHYSICAL theory of nerve is given by Mr. W. M. Strong in the *Journal of Physiology* (xxv. 6). The theory, which is based on the ionic theory of salt solution, assumes all nerves to consist of a semi-solid axis cylinder containing a saline substance in solution. The salt is wholly or partially ionised, so that the axis cylinder is a good electrolytic conductor. Surrounding it is a medullary sheath or outer layer formed of a relatively bad conductor. The negative ion of the salt is supposed to be of a simple nature and to move freely in the semi-solid material of the axis cylinder, while the positive ion only moves with great difficulty. The contraction of a muscle, the author supposes, is directly caused by the arrival of the negative variation at the point where the nerve terminates in the muscle.

THE tenth volume of scientific memoirs edited by Prof. H. Crew and published by the American Book Company, contains reprints of the more important treatises dealing with the "wave theory of light." Beginning with the work of Christian Huygens, the first three chapters of his "Treatise on Light" (1678) are given, describing rectilinear propagation, laws of reflection and refraction; concluding this section is a biographical sketch of the life of Huygens. Next are given three of the historical contributions of Dr. Thomas Young, on the "Theory of Light and Colours," "On the Production of Colours," and "Experiments and Calculations in Physical Optics," followed, also, by a short biographical sketch of the author. The volume is concluded by memoirs of Arago and Fresnel on the "Diffraction of Light" and "Action of Polarised Light," a biography of Fresnel, and a bibliography of the literature at present available on the subject.

WE have received a copy of a report on Hertzian waves drawn up for the recent Physical Congress at Paris by Prof. Augusto Righi, of Bologna. The report deals with the subject from two points of view; the theoretical aspect, which considers the physical identity of Hertzian waves and waves of light, and the practical aspect in connection with wireless telegraphy. Prof. Righi's paper is divided into four sections, the first containing a description of the apparatus used in connection with the production and study of Hertzian waves, the second with radio-conductors, the third with the optical properties of electrical oscillations, and the last with Hertzian telegraphy. Prof. Righi's intimate knowledge of the subject and the important part he himself is known to have played in connection with the invention of wireless telegraphy have eminently qualified him for furnishing physicists with a brief summary of the progress made in this branch of physics since it was first opened up by Hertz.

THE December number of the *Photo-Era*, the American journal of photography, contains many articles of interest. Mr. Yellot reviews the third "Philadelphia Photographic Salon," and evidently does not think very much of it, as he talks of the . . . "dreary monotony about the tier on tier of weak, fuzzy, washed-out-looking photographs. . . ." Landscape composition is another communication worth perusing. Under the heading "Photographing the Aurora," Mr. Stiles describes and illustrates the photograph he obtained at Mount Washington. He used a Ross-Goerz six-inch lens, aperture 7·7, and isochromatic plates, and gave an exposure of 35 minutes. He writes: "What is surprising is the actinic power of the auroral light as compared with the bright moonlight on the snow. Under the aurora is a dark space, which is noted in many displays. This in earlier notes on the aurora was assumed to be dark by contrast, but the photograph shows a quite definite lower boundary."

WE have received from St. Xavier's College Observatory the monthly meteorological results for the months of January to June for the thirty-three years 1868–1900, which we are glad to see will shortly be followed for the other six months, ending December last. The observatory was established in August 1867, and is situated one and a half miles north-east of the Alipore Observatory, and is sufficiently isolated for trustworthy observations. The instruments have been compared with those at either Kew Observatory or the Government Observatory at Alipore, and the observations have been carefully taken several times daily by the fathers in charge, so that the tables form a a very valuable series.

MESSRS. ELSTER AND GEITEL have sent us some further accounts of their interesting experiments on atmospheric electricity. In No. 8, vol. ii. of the *Physikalische Zeitschrift*, papers are communicated on the measurement of electrical leakage in free air, and in closed spaces. Dr. Geitel finds that with regard to the air in a closed vessel, with an initial charge of 240 volts (independently of the sign of electrification) the leakage from an insulated body amounted to about 0·4 per cent. per minute; on the second day the leakage amounted to 1·0 per cent., and on the fourth day to 1·4 per cent. After this period the leakage became slower, and gradually attained a limit of about 2 per cent. per minute. A full description is given of the apparatus employed. He also found that the leakage was not proportional to the charge of electricity, but that for charges varying from 80 to 240 volts the amount remained constant. This phenomenon was pointed out by Matteucci in 1850 (*Annales de Chémie et de Physique*, vol. xxviii.), but the observation remained practically unnoticed. Further, Dr. Geitel found that the influence of daylight, or of artificial illumination, was not perceptible on the results obtained.

THE new number of the *Abhandlungen* of the Vienna Geographical Society consists of an exhaustive paper on the cork-tree, by Eugen Müller. The botany of the cork-tree and the growth and chemical constitution of the cork are first discussed; then follow a lengthy investigation of the geographical distribution of the cork-tree, a history of the production of cork, and a statistical account of the development of the world's trade in cork.

PROF. MITZOPULOS contributes a paper on two of the most remarkable of the seismic disturbances experienced in Greece during the years 1898 and 1899, to *Petermann's Mitteilungen*. The first, the Tripolis earthquake of June 2, 1898, Prof. Mitzopulos believes to have been caused by subterranean falls of rock. The second, or Triphylia earthquake, occurred on January 22, 1899; its epicentrum is located in the Ionian Sea, some 35 to 40 kilometres to the west of the coast of the Peloponnesus, where the bottom goes down in terraces to depths of 2500 to 3500 metres. The epicentrum was probably about 70 kilometres below the sea-bottom.

THE greater part of the December number of the *National Geographic Magazine* is devoted to an account, by Mr. Wilbur C.

Knight, of an expedition to the fossil fields of Wyoming in July 1899. This expedition was organised by the general passenger agent of the Union Pacific Railroad, who issued invitations to every important university, college, and museum in the United States. Each institution was allowed one professor and one or two assistants, who were given free transport from Chicago to Laramie and back. About one hundred men of science joined the expedition, which collected an immense amount of valuable material, including many photographs of geographical interest, some excellent specimens of which illustrate Mr. Knight's article.

WE have received the first number (January 1, 1901) of the *Geologisches Centralblatt*, which is a new fortnightly geological review intended to give titles and brief abstracts relating to all books, papers, maps and tables that have been published on geology, including palæontology and petrography. Twenty-four numbers of thirty-two pages each will be issued yearly. All works issued since April 1, 1900, will be noticed. In the present number there are notices of 104 works, consequently we may expect about 2500 articles to be recorded during the year. We may remark that in the first volume of Whitaker's "Geological Record" for 1874, there were more than 2000 entries, while in Blake's "Annals of British Geology" for 1893 there were 730 entries. The *Geologisches Centralblatt* will not, however, take notice of articles on pure mineralogy and crystallography. It starts with a good list of supporters and contributors, amongst whom are Barrois, Choffat, Reusch, F. D. Adams, and many others, and we observe that British abstracts are furnished by Mr. C. V. Crook, of the Geological Survey Library in Jermyn Street. Abstracts appear in German, English and French. The titles of works in other languages will be translated into one of the before-mentioned languages, and appear beneath the original titles. The *Centralblatt* is divided into sections, but the authors under these sections are arranged promiscuously. The abstracts extend occasionally to a page or even two pages in length; some occupy but a single line. New species of fossils are printed in distinct type, and other species specially referred to are in different type. The work cannot fail to be of the greatest service to geologists in all parts of the world, if only it appears punctually. Messrs. Dulau and Co. act as London agents, and the subscription price is thirty shillings.

THE *Transactions* of the Leicester Literary and Philosophical Society (vol. v., part 10, October 1900) contains three excellent pictorial plates of the pre-Cambrian rocks of Charnwood Forest to illustrate an excursion conducted by Prof. W. W. Watts. The reports of other geological excursions are illustrated by remarkably clear maps and sections prepared by Mr. Fox-Strangways. There are also notes on the botany of the Beaumont Leys Sewage Farm, by Mr. A. B. Jackson, and an address to Section E (Zoology) by Mr. F. R. Rowley. Curiously enough, the entomologists form a section by themselves apart from the zoologists, who are urged by Mr. Rowley to take up the neglected groups of "Rhizopoda, Heliozoa, Infusoria, Turbellaria, Oligochæta, Rotifera, Acarina and Polyzoa."

WE have received from the author, Dr. S. Kaestner, a copy of his inaugural address delivered at the Leipzig Academy on the methods of preparation employed in embryological investigation.

THE excellence of the illustrations forms a striking feature of the latest issue (vol. v. No. 2) of *Indian Museum Notes*. Mr. G. B. Buckton describes one new insect injurious to forest rees, and a second to betel; while the other contributors treat of many kinds of insect pests.

TO the January number of the *Entomologist*, Dr. A. G. Butler contributes some highly interesting observations with regard to the seasonal phases of certain South African butterflies. For instance, the form described as *Precis simia* proves to be the wet season phase of *P. antilope*, and *P. trimeni* that of *P. cuama*. Since these phases are not absolutely confined to season, the indiscriminate use of the term "seasonal form" is deprecated.

ACCORDING to the *American Museum Journal* for November, active steps are being taken for the further zoological exploration of Alaska, Mr. A. J. Stone having already started on a preliminary collecting trip. There is, however, a proposal on foot to start an "Arctic Mammal Club," and it is hoped that the 2000 dollars left conditionally by the late Mr. Constable for the exploration of Alaska will be shortly available. The condition is that the amount should be raised to 5000 dollars by other contributors—and in a rich country like the United States there ought to be little difficulty in getting this sum subscribed.

TO the *Proceedings* of the Washington Academy (vol. ii. pp. 661–676), Dr. Merriam contributes a preliminary revision of the red foxes of North America, of which no less than twelve species and races are recognised. The author regards all these forms as specifically distinct from the common fox of Europe and Northern Asia, although he states that the one described as *Vulpes alascensis* is closely related to the latter, which it connects with the more southern American types. To many zoologists this admission would indicate that all the American red foxes are nothing more than local phases of their Old World prototype. In another part of the same journal (pp. 631–649), Mr. G. S. Miller describes a collection of small mammals from Liberia, among which several are new.

WE have received Prof. Herdman's fourteenth annual *Report* of the Liverpool Marine Biological Committee, and their biological station at Port Erin (Isle of Man). The editor observes that although there is nothing remarkable to record in regard to the educational work of the station, yet all lines of research have been continued and all investigations advanced a stage, while several important publications have been issued. Detailed reports of the laboratory, aquarium and dredging operations are given, and seven plates are appended showing the distribution of the marine fauna at the south-western extremity of the Isle of Man and of particular groups of the same in Port Erin Bay. The preparation of these last must have entailed a vast amount of labour on the part of the staff.

AMONG several other papers, vol. xii., part 2, of the *Proceedings* of the Royal Society of Victoria contains a note by Mr. R. H. Walcott relating to the cast of a fossil tree-trunk in basalt. It was found at Footscray, and shown at the Melbourne Exhibition of 1866. Unlike ordinary fossil stems, in which the wood has been replaced, atom by atom, by mineral matter, the whole of the woody matter in the specimen in question was first destroyed, leaving a cavity which was subsequently filled by liquid trap. A necessary condition for the preservation of the tree-form at the time of the entombment of the specimen seems to have been its rapid inclusion in the molten rock, so that the carbonised remains would be inaccessible to the air, and maintain the mould in its proper shape until the trap had cooled sufficiently to prevent it from closing in. A subsequent flow filled the cavity. The author is of opinion that the specimen cannot be a concretion, and, if he is right, it appears to be unique.

MR. J. E. S. MOORE's account of his researches and explorations in Lake Tanganyika and the countries to the northward, published in the January number of the *Geographical Journal*, will be read with interest both by geologists and zoologists, as

well as by the members of the society before which it was presented. After relating the history of the discovery of the remarkable molluscan fauna of the great lake, and pointing out how it differs essentially in its marine *facies* from that of all the other African lakes, the author refers to the Tanganyika jelly-fish, and concludes that the evidence in favour of the marine origin of the "halolimnic" fauna is overwhelming and irresistible. He then discusses the objections that have been raised against his theory on the ground that, according to an opinion advanced years ago by Sir R. Murchison, no part of the interior of Africa has ever been beneath the sea. This opinion was in part based upon the presumed absence of evidence of volcanic activity in Africa south of the equator. The discovery of volcanoes, both active and passive, in this area, as well as of huge lava-flows, discounts the latter part of the objection, while the evidence of the Tanganyika fauna itself is considered to outweigh the other part.

As regards the outlet by which Tanganyika (presumably as far back as Jurassic times) communicated with the ocean, Mr. Moore adduced evidence to show that, instead of being northwards by way of the other great lakes and the Nile valley, this must apparently have taken place by way of the Congo. The author, from the physical features of the country, was led to believe "that the lake had at some former time extended far to the west of its present site, in the neighbourhood of the Lukuga. It is only necessary for such extension to cover some eighty miles to bring it into communication with the great circular basin of the Congo itself." It is true that the evidence against the original northward extension of the lake is mainly of a negative nature, that is to say, the absence of the halolimnic fauna in the northern lakes; but, as Prof. Lankester observed, negative evidence "has its distinct importance and value as much as positive evidence, and we are in a position to say certainly that the marine fauna of which Mr. Moore has so fully established the existence in Tanganyika did not arise from a northward extension of the lake."

PART iv., completing vol. xxi., of the *Transactions* of the Botanical Society of Edinburgh, contains a second article by Mr. C. E. Hall on tree measurements, from which it would appear that in the tropics, as with us, the chief factor in the growth of trees is rain.

A NEW text-book of botany ("Cours de Botanique," published by Dupont, Paris) is announced, by Profs. Bonnier and Leclerc du Sablon, in two vols. (25 fr.), with upwards of 3000 illustrations, mostly drawn from nature. A new departure is claimed, in the item that the description and anatomy of the organs are taken from a certain number of type-species chosen from widely spread plants.

WE have received the Report of the Moss Exchange Club for the years 1899–1900. Associations of this kind are obviously useful in promoting an interest in their particular branch of science, and the study and determination of critical species. Their danger lies in the destruction of rare and local species, and we should have liked to have seen a hint to this effect in the Report. The honorary secretary of the club, to whom communications are to be addressed, is Mr. C. H. Waddell; but we do not find his address in the Report, which is printed at Stroud.

THE volume of *Knowledge* for 1900 contains numerous splendid collotype plates and other illustrations accompanying articles on subjects belonging to most branches of science.

DR. OLIVER LODGE'S presidential address on the controversy concerning Volta's Contact Force, delivered to the Physical Society at the annual general meeting in February last, is published, with other papers, in the December number of the *Proceedings* of the Society.

THE six monthly numbers of the *Geographical Journal*, from July to December 1900, make up volume xvi., which has just been published by the Royal Geographical Society. The volume contains 766 pages, as well as numerous coloured maps, and is full of matter of interest to the student of geography in all its aspects. Among the many important papers are Dr. C. Hose's account of the natives of Borneo, Captain Deasy's "Journeys in Central Asia," Mr. E. S. Grogan's "Through Africa from the Cape to Cairo," Prof. Haddon's "Studies in the Anthropogeography of British New Guinea," Mrs. Ogilvie Gordon's "Origin of Land-Forms through Crust Torsion," Mr. Borchgrevink's description of the *Southern Cross* Antarctic expedition, and Dr. Donaldson Smith's "Expedition between Lake Rudolf and the Nile." Most of the papers are accompanied by reproductions of photographs of the regions or peoples visited.

THE "Guide to the Babylonian and Assyrian Antiquities" in the British Museum, which has just been published, is a marvel of interest and cheapness, the price being only one shilling. The guide provides notes, interpretations, and thirty-four excellent plates, referring to Babylonian and Assyrian antiquities covering a period of about five thousand years, ranging from about B.C. 4500 to A.D. 500. "In them," Dr. Wallis Budge remarks in the preface, "are comprised by far the largest portion of available material for reconstructing the history of Western Asia, inscribed in the cuneiform character." Dr. Budge's numerous contributions to the science of antiquities have had a profound influence upon intellectual progress; and this new guide, though small in comparison with the works which stand as a monument to his vast knowledge of the past, give students an additional reason for being grateful to him. By the publication of the Guide the Trustees of the British Museum have rendered available a mass of information of interest to students and the public alike.

THE publication of a great work on systematic botany has been commenced by Mr. Englemann, of Leipzig (London: Williams and Norgate), under the title "Das Pflanzenreich." The work has been undertaken by Prof. A. Engler, and is to be a complete record of the plant kingdom. Particulars of the plan of the work, two fascicules of which have been received, are given in Messrs. Williams and Norgate's Book Circular for December. Every one of the 280 families is to form a monograph by itself, with a separate and complete index, the larger families each formin g a separate fascicule. Each family begins with the enumeration of the literature, including monographs, which are restricted to genera, provided they deal with general morphological points, while the purely systematic treatises on genera are quoted with the latter. To each family is attached a complete list of its groups, genera and species, with the generic and specific synonyms. The work is amply illustrated by original drawings, with especial reference to the generic and sectional characters of the plants. This gigantic undertaking will, of course, require many years for its completion; but this is guaranteed, to a great extent, by subventions from the Prussian Government and the Imperial Academy of Sciences. The editor is anxious that it should be known that the present "Pflanzenreich" is not a second edition of the "Natürliche Pflanzenfamilien," supplements to which will continue to be published every few years.

THE much-debated question of the existence of an ammonium amalgam would appear to be finally settled in the affirmative as the result of recent researches. The fact that the volumes of ammonia and hydrogen evolved from ammonium amalgam are in the ratio of 2 : 1 has been regarded as evidence in favour of Berzelius' ammonium theory, but the inability of ammonium amalgam to effect the reduction of the heavy metals from their salt solutions, in opposition to potassium and sodium amalgam,

spoke strongly against the theory. The investigation of the electrolytic tension of decomposition of the ammonium salts with a mercury cathode, by Coehn and Dannenberg (*Zeitschrift für anorganische Chemie*, 25, 430), has given results perfectly analogous to those obtained with salts of the alkali metals, a result only explicable on the assumption of the ammonium theory. Experiments carried out under varying conditions to ascertain the possibility of reducing the heavy metals from their solutions, show that the negative results previously obtained are due to the great instability of the ammonium amalgam. By preparing the amalgam electrolytically at low temperatures (0° C.), when it appears to be much more stable and does not exhibit, to any great extent, the spongy appearance peculiar to the amalgam prepared under ordinary conditions, and allowing it to act on cold solutions of copper, cadmium and zinc salts, the formation of the corresponding heavy metal amalgams is easily observed. In the case of the copper, it might be possible to explain the reduction by attributing it to the nascent hydrogen generated in the decomposition of the ammonium amalgam; but this explanation is not possible in the case of the cadmium and zinc salts.

THE additions to the Zoological Society's Gardens during the past week include a Bonnet Monkey (*Macacus sinicus*) from India, presented by Mr. R. F. Wilson; a Polecat (*Mustela putorius*), British, presented by Mr. Hett; three Painted Snipe (*Rhynchaea capensis*) from India, presented by the Hon. Walter Rothschild, M.P.; a Tawny Owl (*Syrnium aluco*), European, presented by Mr. F. Medcalf; a Deville's Tamarin (*Midas devillii*) from Peru, a —— Conure (*Conurus ocularis*), an Orange-winged Amazon (*Chrysotis amazonica*), a Brazilian Tortoise (*Testudo tabulata*) from South America, three Japanese Pheasants (*Phasianus versicolor*) from Japan, two Pennant's Parrakeets (*Platycercus elegans*), a King Parrot (*Aprosmictus cyanopygius*) from Australia, deposited.

OUR ASTRONOMICAL COLUMN.

ORIGIN OF TERRESTRIAL MAGNETISM.—The *Observatory* for January contains a translation by Prof. L. A. Bauer, of the U.S. Geodetic Service, of an article in *Ciel et Terre*, December 16, 1900, containing the results obtained by Dr. Schmidt from an important harmonic analysis of the permanent magnetic field of the earth. This work has been practically an amplification of Gauss' "Théorie générale du magnétisme terrestre."

In Schmidt's analysis he does not assume the existence of an interior potential function governing the entire magnetic force; but adjusting separately each of the three rectangular components, obtains three expressions in place of the one determined by Gauss; moreover, the computations have been carried to the terms of sixth order instead of the fourth. He concludes that the magnetic force of the earth consists of three parts:—

(1) *The greatest part*, attributed to causes situated in the terrestrial crust, and having a potential.

(2) *The smallest part* (about one-fortieth the whole), due to causes exterior to the crust, and also possessing a potential.

(3) A part, somewhat greater than (2), not represented by a potential, and therefore indicating the existence of *vertical* terrestrial electric currents.

Dr. Schmidt has also made careful examinations of the records of magnetic storms. In that of February 28, 1896, which was observed at fifteen observatories, and lasted from 6-7 o'clock, he finds that the directions of disturbance vary considerably, at times converging to a point, at others radiating from a point; while at certain periods of comparative calm the lines of force were practically parallel, suggesting a distant centre of force. Taking these facts in consideration with the vertical component disturbances, he concludes that the causes producing terrestrial magnetic storms are for the most part exterior to the surface of the earth.

OPPOSITION OF MARS IN 1888.—Signor G. V. Schiaparelli has recently published a sixth volume of observations of Mars, containing the discussion of his determinations on the topography and constitution of the planet during the opposition of 1888, made with the 18-inch Merz refractor at the Milan Observatory. After preliminary notes of instrumental details and tables showing varying size of the disc, atmospheric quality, &c., about eighty pages are devoted to the detailed description of the aspects of the many markings recognised during the period, very many comparisons with the work of other observers being included; the remainder of the volume is occupied with the discussion of observations bearing on the constitution of the surface, giving detailed measures and descriptions of the varying polar caps, and a comparative analysis of the gemination of the principal "*canali*." Reproductions of drawings of the surface markings on successive dates are included, and two polar charts showing the whole of the observed phenomena in their relative longitudes.

DOUBLE STAR MEASURES.—In the *Astronomische Nachrichten* (Bd. 154, No. 3679) Mr. J. Comas Sola gives a series of measures of seventy-five double stars observed at Barcelona.

SCIENTIFIC DEVELOPMENTS OF BIOLOGY AND MEDICINE.

AN interesting monograph is just to hand in the shape of a lecture, delivered by Dr. Oscar Hertwig upon the occasion of the congress of German naturalists at Aix la Chapelle (Aachen). The subject is the development of biology in the nineteenth century. Many interesting points, forming landmarks in the progress of biological science, are discussed by the lecturer. The microscope, from the inestimable service it has rendered to morphology, must rank high in the discoveries of the century. Before morphological method had been enriched by it, the cellular hypothesis, which is the foundation stone of all biology, was impossible. Dr. Hertwig accentuates the fact that progress consists, not only in adding facts to our treasury of knowledge, but also in stamping out error, and that some of the biological energy of the nineteenth century has been consumed in annihilating the doctrine of spontaneous generation; it was, indeed, only Pasteur's researches that established irrefutably the dictum *Omne vivum e vivo*, and much later still did the corollary of this, namely *Omnis cellula e cellula*, firmly plant itself upon biology, never to be uprooted.

A further factor of transcendental importance in the progress of biology during the nineteenth century was the birth and growth of the study of embryology. Its chief result was the theory of evolution and the accompanying doctrines of natural selection and the survival of the fittest. The lecturer enters fully into the literature of this subject, which has moved the biological world perhaps more than any preceding one. The concluding part of the discourse is devoted to the progress made in that department of biology which we know as physiology. The attempt in this direction during the latter part of the century has been to reduce, by means of physico-chemical technique, biological phenomena to physico-chemical law. This attempt, although it has given us an enormous insight into the processes of life and has enabled us to formulate laws of the highest abstract and utilitarian value, has been, in its absolute sense, unsuccessful. It is doubtful if chemical and physical law can ever explain fully the phenomena of life, and while physiological chemistry and physics have destroyed the old vitalism, we are, to some extent, compelled to take refuge in a new one. From the practical standpoint, great progress has been made in the development of pharmacology and experimental pathology. The former, going hand in hand, as it ever must, with the practical treatment of disease, has not only thrown light upon many problems of pathology and physiology, but has greatly increased the possibilities of therapeutics, and given distinct hope for the future in this direction. Under experimental pathology serum therapy is included, and the immense field for research this has opened up.

An address delivered by Dr. Naunyn, of Strassburg, at the same congress, is of considerable interest. He chose for his subject the development of medicine, hygiene and bacteriology during the nineteenth century. To show the condition of medical thought at the beginning of the century, he quotes from the work of Prof. Kieser, of Jena, in 1812. At that time the exanthemata were regarded as necessary stages in the growth of mankind, and as essential to his perfect development, just as the pupa stage is essential to the butterfly. The scientific development of medicine, according to Prof. Naunyn, took its first real

impetus from the work of Johannes Müller. His text-book of physiology was a book which focussed the work of preceding generations for the purpose of pointing out the direction which the work of succeeding generations should take. This, and the subsequent discoveries of Laennec, formed the first scientific basis of medicine. The next step forward was the founding and development of morbid anatomy, going hand in hand with clinical medicine; in fact, any further progress of the latter without the former was impossible. In this respect the Vienna School, as exemplified by the clinician Skoda, working in connection with the pathologist Rokitansky, did giant service. Subsequently the researches of Pasteur, upon fermentation, and the antiseptic work of Lister form striking monuments in the century's progress. The latter was of value, according to the author, in a somewhat unanticipated direction, in that it rendered explorative operations possible, and thus enabled clinicians to observe disease in a stage short of that which it presented at the post-mortem examination. Last, but not least, Prof. Naunyn refers to the rise and the progress made by pharmacology, and points out the brilliant therapeutical results which have issued from pharmacological research.

THE DISTRIBUTION OF VERTEBRATE ANIMALS IN INDIA, CEYLON AND BURMA.[1]

THE completion of the seven volumes containing descriptions of all the vertebrata, in the "Fauna of British India," affords an opportunity of reviewing generally the distribution of terrestrial vertebrate animals throughout the British possessions in India, Ceylon and Burma.

For the study of zoological distribution there are few, if any, regions on the earth's surface that exceed British India and its dependencies in interest. The area is about 1,800,000 square miles, and although the vertebrate fauna is by no means thoroughly explored, it is well known throughout the greater part of the area and fairly known throughout the whole, better, probably, than in any other tropical and sub-tropical tract of approximately equal extent. The variety of climate is remarkable; within the area are included the almost rainless deserts of Sind and the locality on the Khási Hills, distinguished by the heaviest rainfall known, the cold, arid plateau of the Upper Indus drainage, and the damp tropical forests of Malabar and Tenasserim. The country is bounded on the north by the highest mountain range in the world and on the south by an ocean extending to the Antarctic regions. Another element of interest lies in the fact that the peninsula of India is a land of great geological antiquity, there being no evidence that it has ever been submerged, although the greater part of the Himalayas and Burma have at times been beneath the sea.

The plan adopted for the study has been to divide the whole country into nineteen tracts, distinguished by physical characters —such as rainfall, temperature, presence or absence of forests, and prevalence of hilly ground, and to construct tables showing the distribution of each genus of land or fresh-water vertebrate in the tracts. Genera have been selected for consideration because families and sub-families are too few in number and too wide in range, whilst species are too numerous and too unequal in importance. In the demarcation of regions and sub-regions, terrestrial mammalia are regarded as of primary importance.

The tracts are the following:—

A. *Indo-Gangetic Plain.*

1. Punjab, Sind, Baluchistan and Western Rajputana.
2. Gangetic Plain from Delhi to Rajmahal.
3. Bengal from Rajmahal to the Assam Hills.

B. *Indian Peninsula.*

4. Rajputana and Central India as far south as the Nerbudda.
5. Deccan from the Nerbudda to about 16° N. lat. and from the Western Ghats to long. 80° E.
6. Behar, Orissa, &c., from the Gangetic Plain to the Kistna.
7. Carnatic and Madras, south of 5 and 6, and east of the Western Ghats.
8. Malabar Coast, Concan and Western Ghats or Sahyádri range from the Tapti River to Cape Comorin.

[1] Abridged from a paper read at the Royal Society, on December 13, 1900, by Dr. W. T. Blanford, F.R.S.

C. *Ceylon.*

9. Northern and Eastern Ceylon.
10. Hill Ceylon, the Central, Western and Southern Provinces.

D. *Himalayas.*

11. Western Tibet and the Himalayas above forest.
12. Western Himalayas from Hazára to the western frontier of Nepal.
13. Eastern Himalayas, Nepal, Sikhim, Bhutan, &c.

E. *Assam and Burma.*

14. Assam and the hill ranges to the south with Manipur and Arrakan.
15. Upper Burma, north of about 19° N. lat.
16. Pegu from the Arrakan Yoma to the hill ranges east of the Sittang.
17. Tenasserim as far south as the neighbourhood of Mergui.
18. South Tenasserim, south of about 13° N. lat.
19. Andaman and Nicobar Islands.

A review of the fauna of these tracts leads to the following conclusions:—

(1) The Punjab tract differs greatly in its fauna from the Indian Peninsula and from all countries to the eastward, so greatly that it cannot be regarded as part of the Indo-Malay or Oriental region. Of terrestrial mammals, bats excluded, 30 genera are met with, of which 8 or 26½ per cent. are not Indian, whilst of reptiles (omitting crocodiles and chelonians) 46 genera occur, and of these 20 or 43½ per cent. are unknown further east. Of the corresponding orders of mammalia 46, and of reptiles 80 genera occur in the Peninsula, and 24 or 52 per cent. of the former and 57 or 64 per cent. of the latter are not found in the Punjab tract. All the genera met with in the Punjab tract and wanting further east are either Holarctic forms or peculiar, but with Holarctic affinities.

The Punjab, Sind and Western Rajputana are in fact the eastern extremity of the area known as the Eremian or Tyrrhenian or Mediterranean sub-region, generally regarded as part of the Holarctic region, but by some classed as a region by itself corresponding to the Sonoran in North America.

(2) The Himalayas above the forests and such portions of Tibet as come within Indian political limits (Gilgit, Ladák, Zanskar, &c.) belong to the Tibetan sub-region of the Holarctic region. Of twenty-five mammalian genera hitherto recorded from No. 11 (the Tibetan) tract, 11 or 44 per cent. are not found in the Indo-Malay region. That Tibet forms a distinct mammalian sub-region has already been shown in other papers.

(3) India proper from the base of the Himalayas to Cape Comorin, and from the Arabian Sea and the eastern boundary of the Punjab tract to the Bay of Bengal and the hills forming the eastern limit of the Gangetic alluvium, should, with the addition of the island of Ceylon, be regarded as a single sub-region, and may be conveniently entitled the Cisgangetic sub-region. The forests of the Sahyádri range and of the western, or Concan and Malabar, coast and the hill area of Southern Ceylon have a far richer fauna than the remaining area, but are not sufficiently distinct to require sub-regional separation.

The Cisgangetic sub-region is distinguished from the Transgangetic by the presence amongst mammals of Hyænidæ, Erinaceinæ, Gerbillinæ, of three peculiar genera of antelopes and of some other types; amongst birds by the occurrence of Pterocletes (sand grouse), Phœnicopteri (flamingoes), Otididæ (bustards) and Cursoriinæ; amongst reptiles by the possession of the families Eublepharidæ, Chamæleontidæ and Uropeltidæ, together with many peculiar Geckonidæ, Agamidæ, Lacertidæ and Scincidæ, and amongst batrachians by about one-half of the genera found in each sub-region being absent in the other. The difference between the reptiles and batrachians by itself would justify the classification of the two areas as distinct regions, a view adopted by several writers.

The difference between the Cisgangetic vertebrate fauna and that inhabiting the rest of the Indo-Malay or Oriental region is partly due to the absence in the former of numerous Eastern types, and partly to the presence of two constituents besides the Oriental genera, which, especially in forest, form a majority of the animals present. One of these two constituents consists of mammals, birds and reptiles having a distinct relationship with Ethiopian and Holarctic genera, and with the Pliocene

Siwalik fauna. This constituent of the Cisgangetic fauna it is proposed to distinguish by the term Aryan. The other constituent is composed of reptiles and batrachians and may be termed the Dravidian element. The latter is well developed in the south of the Peninsula and especially along the south-west or Malabar coast, and in Ceylon, but it gradually disappears to the northward, its northern limit, so far as is known at present, not extending to the 20th parallel of north latitude. It is probable that this is the oldest part of the Cisgangetic fauna, and it may have inhabited the country since India was connected by land with Madagascar and South Africa, across what is now the Indian Ocean, in Mesozoic and early Cenozoic times. The other two elements, the Indo-Malay or Oriental and the Aryan, are probably later immigrants, and its wider diffusion may indicate that the Indo-Malay element has inhabited the Indian Peninsula longer than the Aryan has. There appears some reason for regarding the Indo-Malay portion of the fauna as dating in India from Miocene times and the Aryan from Pliocene, whilst in the Pleistocene epoch the proportion of Aryan to Indo-Malay types of mammals in India, as shown by the fossil faunas of the Nerbudda and the Karnul caves, was much larger than at the present day.

There are some other peculiarities of the Indian Peninsula fauna to which attention may be called. One of these is the presence of genera and sometimes of species which are found on both sides of the Bay of Bengal, but not in the Himalayas or Northern India. A good example is afforded by the genus *Tragulus*, of which one species inhabits Ceylon and India south of about 22° N. lat., whilst two others are found in Southern Tenasserim and the Malay Peninsula. In Pliocene times the genus inhabited Northern India. Another instance is the lizard *Liolepis guttatus*, found in Burma and Arrakan and also in South Canara on the west coast of India. Examples amongst reptiles are rather numerous. Moreover, whilst there are numerous alliances between the animals of Peninsular India and those of Africa, there are also some curious connections between India and Tropical America, but these are chiefly amongst invertebrates. Some, however, are found in reptiles. It is probable that such Indo-American connections are vestiges of older life than the Indo-African. They are, of course, generally speaking, instances of animal groups once more widely distributed, but now only preserved in a few favourable tropical localities.

(4) The forest area of the Himalayas belongs to the same sub-region as Assam, Burma (except South Tenasserim), Southern China, Tonquin, Siam and Cambodia, and to this sub-region the term Transgangetic may be applied. It is distinguished from the Cisgangetic sub-region by the absence of the animals already specified as characteristic of that area and by the presence of the following, which are wanting in the Indian Peninsula—Mammals: the families Simiidæ, Procyonidæ, Talpidæ and Spalacidæ, and the sub-family Gymnurinæ, besides numerous genera such as *Prionodon*, *Helictis*, *Arctonyx*, *Atherura*, *Nemorhaedus* and *Cemas*. Birds: the families Eurylæmidæ, Indicatoridæ and Heliornithidæ, the sub-family Paradoxornithinæ. Reptiles: Platysternidæ and Anguidæ. Batrachians: Discophidæ, Hylidæ, Pelobatidæ and Salamandridæ.

The relations of the Himalayan fauna to that of Assam and Burma on the one hand, and to that inhabiting the Peninsula of India on the other, may be illustrated by the mammals with bats omitted. Of forty-one genera occurring in the Himalayas, three are not found in the hills south of Assam or in Burma, whilst sixteen are wanting in the Cisgangetic region. It should be remembered that a large number of the genera are widespread forms. As the result is not in agreement with the views of some who have written on the subject, the relations of species have been examined. It results that eighty-one species of mammalia, belonging to the orders Primates, Carnivora, Insectivora, Rodentia and Ungulata, are recorded from the forest regions of the Himalayas. Of these two are doubtful, twenty-two are not known to occur south of the Himalayan range in India or Burma, twenty-one are wide ranging forms and are found in both Burma and the Indian Peninsula, one only (*Hystrix leucura*) is common to the Himalayan forests and the Indian Peninsula, but does not range east of the Bay of Bengal, whilst thirty-five are found in the countries east of the Bay of Bengal but not in the Peninsula south of the Ganges. Of the thirty-five, eight only range as far as the hills south of the Assam Valley, sixteen to Burma proper, and eleven to the Malay Peninsula and Archipelago. Of the twenty-two species not ranging south of the Himalayas a large majority are either Holarctic species or belong to Holarctic genera.

The fauna of the Himalayan forest area is partly Holarctic, partly Indo-Malay. It is remarkably poor, when compared with the Cisgangetic and Burmese faunas, in reptiles and batrachians. It also contains but few peculiar genera of mammals and birds, and almost all the peculiar types that do occur have Holarctic affinities. The Indo-Malay element in the fauna is very richly represented in the Eastern Himalayas, and gradually diminishes to the westward until in Kashmir and farther west it ceases to be the principal constituent. These facts are consistent with the theory that the Indo-Malay constituent of the Himalayan fauna, or the greater portion of it, has migrated into the mountains from the eastward at a comparatively recent period. It is an important fact that this migration appears to have been from Assam and not from the Peninsula of India.

(5) Southern Tenasserim agrees best in its vertebrata with the Malay Peninsula, and should be included in the Malayan sub-region of the Indo-Malay region.

There are several points left which require explanation. There is the much greater richness of the Oriental constituent in the Cisgangetic fauna to the southward in Malabar and Ceylon, although this is far away from the main Oriental area, and the ocurrence also in the southern part of the Peninsula of various mammalian, reptilian and batrachian genera, such as *Loris*, *Tragulus*, *Draco*, *Liolepis* and *Ixulus*, which are represented in Burma and the Malay countries but not in the Himalayas or Northern India. In connection with this the limitation of the Dravidian element to the south of India should also be remembered. Then there is the occurrence of certain Himalayan species on the mountains of Southern India and Burma and even farther south, but not in the intervening area. There is also the predominance of the Western, or what I have proposed to call the Aryan, element in the Pleistocene fauna of the Nerbudda Valley, and of Karnul in the north of the Carnatic tract. Lastly, we have to account for the apparently recent immigration of Oriental types into the Himalayas.

Whilst it is quite possible that other explanations may be found, it is evident that all these peculiarities of the Indian fauna may have been due to the Glacial epoch. The great terminal moraines occurring at about 7000 feet in Sikhim and the occurrence of similar moraines and other indications of ice action at even lower levels in the Western Himalayas clearly show that the temperature of the mountain range must have been much lower than at the present day, when no glacier in Sikhim is known to descend below about 14,000 feet.

During the coldest portion of the Glacial epoch, a large part of the higher mountains must have been covered by snow and ice, and the tropical Indo-Malay fauna which had occupied the range, and which may have resembled that of the Indian Peninsula more than is the case at present, must have been driven to the base of the mountains or exterminated. The Holarctic forms apparently survived in larger numbers. The Assam Valley and the hill ranges to the southward would afford in damp, sheltered, forest-clad valleys and hill slopes a warmer refuge for the Oriental fauna than the open plains of Northern India and the much drier hills of the country south of the Gangetic plain. The Oriental types of the Peninsula generally must have been driven southwards, and some of them, such as *Loris* and *Tragulus*, which must originally have been in touch with their Burmese representatives, have never returned. It was probably during this cold period that the ossiferous Nerbudda beds and the deposits in the Karnul caves were accumulated. The tropical damp-loving Dravidian fauna, if it inhabited Northern India, must have been driven out of the country. Unless the temperature of India and Burma generally underwent a considerable diminution, it is not easy to understand how plants and animals of temperate Himalayan types succeeded in reaching the hills of Southern India and Ceylon, as well as those of Burma and the Malay Peninsula.

When the whole country became warmer again after the cold epoch had passed away, the Transgangetic fauna appears to have poured into the Himalayas from the eastward. At the present day the comparatively narrow Brahmaputra plain in Assam is far more extensively forest-clad, especially to the eastward, than is the much broader Gangetic plain of Northern India, and if, as is probable, the same difference between the two areas existed at the close of the Glacial epoch, it is easy to see how much greater the facilities for the migration of a forest-haunting fauna

must have been across the Brahmaputra Valley than over the great plain of the Ganges. This difference alone would give the Transgangetic fauna of Burma an advantage over the Cisgangetic fauna in a race for the vacant Himalayas, even if the latter had not been driven farther to the southward than the former, as it probably was during the Glacial epoch.

The theory, however, is only put forward as a possible explanation of some remarkable features in the distribution of Indian vertebrates. At the same time it does serve to account for several anomalies of which some solution is necessary. If thus accepted, it will add to the evidence, now considerable, in favour of the Glacial epoch having affected the whole world, and not having been a partial phenomenon induced by special conditions, such as local elevation.

SCIENCE TEACHERS IN CONFERENCE.

FOR the third time the Technical Education Board of the London County Council has arranged and held a conference of teachers of science from all parts of the kingdom. Since their inauguration, these annual meetings have steadily grown in popularity. At the first conference, in 1899, there was an attendance of eighty persons, in 1900 the number had grown to 200, while at the meetings held last week the attendance reached the total of 350. These satisfactory results are largely due to the efforts of Mr. C. A. Buckmaster, of the Board of Education, and Dr. Kimmins, the Inspector to the Technical Education Board, who have steadily worked during the three years in encouraging lecturers, demonstrators and inspectors to meet together for the discussion of methods of teaching different branches of science. The addresses and papers brought before the conference at the South-Western Polytechnic, Chelsea, on January 10 and 11, dealt with subjects of great importance in an interesting and instructive manner; but the discussions were not entirely satisfactory. It is useless to expect teachers to contribute anything valuable to a discussion at a moment's notice. It should be possible at future meetings to obviate in a large measure the desultory speeches on more or less general topics which this year followed the addresses and papers. If half a dozen well-known, practical teachers were given an abstract of the paper before the meeting, they would be able, with a few days' preparation, to place succinctly before the meeting the results of their own practice, and besides putting the discussion on right lines, they would lead other teachers with experience of the matter in hand to help forward a complete presentation of the subject.

One more preliminary remark is necessary. Too much was attempted at separate meetings, at some of which as many as three papers were read and put down to be discussed in two hours. The consequences were unfortunate. To name one instance only: at the third meeting, not only was Prof. Armstrong unable to deliver the whole of the paper he had prepared on the teaching of domestic science, but though the discussion was continued some fifteen minutes after the proper time, he was not called upon to reply to the points raised by different speakers. It is to be hoped that next year fewer subjects will be taken up at each meeting, and more pains taken to secure an ample discussion, rigidly kept to the matter in hand.

INSTRUMENT MAKING.

At the first meeting of the conference, Mr. T. A. Organ, the Chairman of the Technical Education Committee of the London County Council, presided. In his introductory remarks the Chairman insisted on the need there is still for improved science teaching in our schools, and directed attention to a growing danger of doing too much for students. What has been called in America "peptonised" education seems to be on the increase, and is much to be deprecated. Addresses were given on "Instrument-making for schools and technical classes," by Mr. W. Hibbert, of Regent Street Polytechnic; and on the "Co-ordination of workshop and laboratory instruction," by Mr. T. P. Nunn, of William Ellis's School, and Mr. A. G. Hubbard, of Raine's School. During the course of his remarks, Mr. Hibbert described, with the aid of lantern slides, a large number of simple pieces of apparatus for use in the teaching of electricity and magnetism, amongst which his magnetometer, which can be easily converted into an astatic galvanometer, his electroscope, capable of detecting one-tenth the potential difference recognisable by the ordinary forms of instrument, and his standard magnets are particularly worth mention. The remaining addresses described successful attempts to make the work of the manual instruction teacher assist the practical study of physics. In the subsequent discussion, Dr. Gladstone, F.R.S., referred to the efforts he had made on the London School Board in the direction of supplying the teachers of the schools of the Board with simple, inexpensive apparatus which would satisfactorily demonstrate the elementary principles of physics and chemistry.

THE FITTING UP OF LABORATORIES.

Sir W. de W. Abney, K.C.B., F.R.S., took the chair at the second meeting, and lectures were given by Messrs. J. B. Coleman, A. Schwartz and W. W. Pullen, describing the fittings and apparatus of the chemical, physical and mechanical laboratories, of which they respectively have charge at the South-Western Polytechnic. After the addresses, which were profusely illustrated with lantern slides, a discussion was opened by Prof. Armstrong, F.R.S. Referring to the provision which Mr. Coleman has made for the proper writing of notes in the laboratory itself at the time the practical exercise in science is actually performed, Prof. Armstrong urged that one of the most valuable results from intelligent science teaching is the excellent progress the pupil makes in his ability to express himself in a literary manner when called upon to systematically describe the work he has performed. He also urged that it is a great mistake to suppose that palatial establishments, such as those described by the lecturers, are really necessary for teaching science to boys and girls. Pretentious "drawing-room" laboratories are by no means desirable; what is wanted is not so much a laboratory as a workshop, which need be little more than a shed, such as a contractor about to put up a large building erects for the use of his workmen. Students who work in the sumptuously-fitted places now provided are not suitably trained for the work of life; nobody in commercial undertakings gets a place anything like as good as a school laboratory in which to do his professional work. The thing of importance is the spirit with which the work is undertaken, not the number of appliances at the disposal of the teacher and pupil.

In acknowledging a vote of thanks, and at the same time summarising the papers and discussion, Sir W. Abney explained that his experience in connection with the Board of Education at South Kensington has shown him what a great deal can be done with very simple apparatus. He had, he said, again and again met, in different parts of the country, teachers using the simple pieces of physical apparatus they had made in the laboratories of the Royal College of Science during the courses of instruction arranged for them there during the summer vacation. The teacher of science who has learnt how to make and devise these simple pieces of apparatus can, with the aid of his pupils, easily turn out apparatus quite suitable for satisfactorily demonstrating the important laws of chemical and physical science.

DOMESTIC SCIENCE.

The third meeting, over which Mr. Bousfield, Chairman of the Girls' Public Day School, presided, was devoted to a consideration of the science teaching in girls' schools, especially as to what form of instruction in domestic science is desirable. The first paper was read by Miss Aitken, of the North London Collegiate School, who gave it as her opinion that the best practical teaching in science for girls is given in the now well-known schools of science held in connection with the South Kensington branch of the Board of Education. The generality of girls' schools are not, Miss Aitken finds, properly provided with necessary and suitable accommodation for the pupils to themselves make experiments with simple apparatus, the classes in science are too large, and the amount of time placed at the disposal of the science mistress is ludicrously inadequate.

Prof. Armstrong, in a paper on the teaching of domestic science, laid it down that the object of their instruction should be the formation of habits, not the accumulation of knowledge. Elementary work, in what Prof. Armstrong prefers to call *νους* or "knowingness" rather than science, should throughout aim at developing and strengthening a young pupil's mother wit. Anything may be taught and in any way, provided it leads to the cultivation of *νους*. All teaching in domestic science must be guided by considerations of this kind, and the fundamental subjects of a suitable course will be measuring work, which will not be unduly prolonged, but give place at an early stage to continued exercises with the balance; the study of the

properties of water will follow, after which the effects of heat can with advantage be taken up, and so prepare the way for the final stage of the preliminary course—namely, the study of the air, more particularly in relation to the part it plays in the combustion of food and fuel. But throughout the course constant work with the balance must take a prominent part. The balance inculcates thrift and morality generally, and weighing should be so constantly resorted to that it becomes an absolute habit. If Rudyard Kipling could but be persuaded to write a song with the refrain "Weigh, weigh, weigh," which could be hummed by girls during their lessons in practical work in science, as well as sung on State occasions, he would be doing education a great service.

Prof. Tilden, F.R.S., opened a discussion and referred to the neglect of book-keeping in household management, and directed attention to the fact that a sound education must take notice of other subjects than science.

PSYCHOLOGY AND SCIENCE TEACHING.

Sir Henry Roscoe, F.R.S., took the chair at the concluding meeting, at which Prof. Earl Barnes gave an address on nature teaching for young children, and Principal Lloyd Morgan, F.R.S., lectured on psychology and science teaching. Prof. Morgan said a lecturer in psychology had been defined thus by a pupil—"He tells us what every one knows in language which nobody can understand," but he hoped to avoid the dangers mentioned in the definition. It is easier to indicate what is not education than to give a satisfactory account of what it is: "when one fellow talks about what he doesn't understand to other fellows who don't understand him, that's *not* education." The teacher ignorant of psychology is somewhat of a quack, the honest and earnest instructor must have some practical knowledge of mental processes. In fact, all science teachers ought to take a course in psychology as part of their recognised curriculum in training for their life-work. But such work in psychology should have an experimental basis; the professor and his students must participate in an investigation together. Prof. Morgan then described, with a series of practical demonstrations, the research he was assisting his own students to carry out. In all such practical work it is borne in mind that the first stage in a normal course of mental sequence is that of observation presenting facts which demand explanation; the second that of discovery; and the third that of testing and applying the principles. A discussion followed in which the chairman and Dr. Gladstone took part.

A collection of home-made apparatus for science teaching in schools was on view during the days of the conference, and the chemical, physical and mechanical laboratories of the Polytechnic were open for inspection. A. T. SIMMONS.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The Sedgwick prize in geology has been awarded to Mr. F. R. C. Reed, M.A., of Trinity College.

At Peterhouse the following entrance scholarships in Natural Science have been awarded: Blackie, Tonbridge School, 50*l.*; King, City of London School, 40*l.*

THE University of Cincinnati was re-organised in the latter part of last year, and an account of the changes, with photographs and short biographical sketches of the Faculty as now constituted, is given in *Chic.* The most distinctive change is the introduction of the elective system, which permits the student to follow the course of study which best suits his needs for the profession or business he intends to follow after leaving the University. A college of commerce and administration is in contemplation, which will have for its object practical instruction in methods of business in conformity with modern demands. The endowment fund of the University, through the bequests of a number of generous benefactors, amounts to the substantial sum of 3,357,308 dollars, or more than 700,000*l.* The president of the University is Dr. H. Ayres, formerly professor of biology in the University of Missouri.

Literature remarks:—The close of the term for the Christmas vacation has shown the interest of the American millionaire in the advancement of learning. Mr. J. D. Rockefeller gives 300,000*l.* to the University of Chicago and 3000*l.* to the Vermont Academy. Wellesley College, Mass., receives 20,000*l.* from various donors, and Ripon College, Wisconsin, comes into possession of a handsome building for scientific study, the gift of Mr. O. H. Ingram. The Universities have, on the whole, done well by the millionaires. Here is a summary of the largest endowments and their givers:—

Chicago University	J. D. Rockefeller	$9,133,874	£1,902,848
Gerard College	Stephen Gerard	7,000,000	1,458,333
Pratt Institute	Charles Pratt	3,600,000	750,000
Johns Hopkins Univ.	Johns Hopkins	3,000,000	625,000
Drexel Institute	A. J. Drexel	3,000,000	625,000
L. Stanford University	Leland Stanford, jun.	2,500,000	520,833
Cornell University	Ezra Cornell	1,500,000	312,500
Vanderbilt University	The Vanderbilts	1,100,000	229,166
Columbia University	Seth Low	1,000,000	208,333

But there are millionaires outside of America, and the list may at any rate be taken as an example *pour encourager les autres.*

SCIENTIFIC SERIALS.

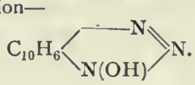
American Journal of Science, January.—The stereographic projection and its possibilities, from a graphical standpoint, by S. L. Penfield. Two stereographic protractors devised by the author are described, and detailed instructions given for their use. These protractors are especially adapted to crystallographic problems, but this branch of the subject is postponed for special consideration in a further communication.—On the mode of occurrence of topaz near Ouro Preto, Brazil, by Orville A. Derby. The yellow Brazilian topaz of the Ouro Preto district was stated by Eschwege to occur in association with talcose or chlorite schist, and this was confirmed to some extent by Mawe, Spix and Martius. This view was contested by Gorceix, who found that the unctuous schists of this region are essentially micaceous. The results of the author's researches in this district show that the occurrence of the topaz here does not differ so materially from the other known ones as has hitherto been supposed. The mineral does not occur in an essentially magnesian rock, nor is its matrix of presumably sedimentary rather than of eruptive origin.—A chemical study of the glaucophane schists, by Henry S. Washington. Analyses of glaucophanes from Syra, Oregon, Croatia, Anglesey, California, Japan and Piedmont, sixteen analyses in all. The glaucophane schists are found to belong to two classes. The larger one is basic, and consists chiefly of glaucophane and epidote, and scarcely differs in chemical composition from the amphibolites and eclogites. A smaller, but widely spread group, is acid in composition, and these are composed largely of quartz and glaucophane.—On the nature of the metallic veins of the Farmington meteorite, by O. C. Farrington. The question of the origin of the metallic veins in a meteorite is of interest as throwing light on the origin, terrestrial or pre-terrestrial, of the meteorite. Preston's views on the veins in the Farmington meteorite are discussed and shown to be improbable.—*Erigenia bulbosa*, by Theo. Holm. An examination of the question as to whether the globular underground part of this plant is a true tuber or a tuberous root. After some trouble, specimens of the plant were obtained in the seedling stage, and the bulb was found to be a tuberous root.—New species of Merycochœrus, in Montana, by Earl Douglass. This species, described as *M. altiramus*, found in the Madison Lake beds of the Loup Fork epoch, is represented by a right mandibular ramus which only lacks the posterior border and some other small fragments. The paper is illustrated by five diagrams of the dentition, accompanied by careful measurements.

Bulletin of the American Mathematical Society, December, 1900.—Prof. F. N. Cole gives an account of, with abstracts of the papers read at, the October meeting of the Society. As these papers will be printed *in extenso* in the *Bulletin*, or in the *Transactions*, we omit the consideration of them here. Prof. M. Bôcher devotes a page to a note on linear dependence of functions of one variable. Report on the groups of an infinite order, by Dr. G. A. Miller, was read before Section A of the American Society for the Advancement of Science, which met at New York in June last. This is a useful *résumé* of recent work done upon the theory of groups, with copious references to original memoirs. Two reviews follow, viz., of Ewing's "The Strength of Materials," by Dr. C. Chree, and of the "Anwendung der Differential- und Integralrechnung auf Geometrie" of Dr. G. Scheffers (Bd. i. "Einführung in die Theorie der Curven in der Ebene und im Raum"), by Prof. J. M. Page. Notes and new publications close the number.

SOCIETIES AND ACADEMIES.

LONDON.

Chemical Society, December 13, 1900.—Prof. Thorpe, President, in the chair.—Prof. H. A. Miers delivered the Rammelsberg Memorial Lecture.—December 20, 1900, Prof. Thorpe, President, in the chair.—On the union of hydrogen and chlorine, by J. W. Mellor. The mixture of hydrogen and chlorine obtained by the electrolysis of hydrochloric acid always contains measurable quantities of oxygen. A slight contraction occurs on mixing gaseous chlorine and hydrogen chloride.—The nitration of the three tolueneazophenols, by J. T. Hewitt and J. H. Lindfield. The three tolueneazophenols are nitrated by warm dilute nitric acid, and in each case the nitro-group enters the phenol ring in the ortho-position relatively to the hydroxyl group.—The bromination of the ortho-oxyazo-compounds and its bearing on their constitution, by J. T. Hewitt and H. A. Phillips. Ortho-oxyazo-compounds appear to react towards bromine as true oxyazo-compounds, and not as orthoquinone-hydrazones.—On the use of pyridine for molecular weight determinations by the ebullioscopic method, by W. R. Innes. Molecular weight determinations show that pyridine does not favour the association of dissolved substances; its molecular rise in boiling point is 29·5.—The influence of the methyl group on ring formation, by A. W. Gilbody and C. H. G. Sprankling. The authors have determined the stability of phenylsuccinimide and its alkyl derivatives in alcoholic solution. It is found that the stability of the succinimide ring is decreased by introducing methyl groups into the fatty ring, whilst Miolati has found that the introduction of fatty groups into the aromatic ring increases the stability.—Experiments on the production of optically active compounds from inactive substances, by F. S. Kipping.—A lecture table experiment for the preparation of nitric oxide, by A. Senier.—The action of ethylene dibromide on xylidine and pseudocumidine, by A. Senier and W. Goodwin.—The action of phenylcarbimide on diphenyl-, dialphyl- and dinaphthyl-diamines, by A. Senier and W. Goodwin.—Note on the action of nitrous acid on β-nitroso-α-naphthylamine, by A. Harden and J. Okell. On treating β-nitroso-α-naphthylamine in alcoholic solution with potassium nitrite and hydrochloric acid, a salt of the composition $C_{10}H_6O_2N_3K$ is obtained; this and the corresponding sodium salt, when treated with stannous chloride and acid, yield a substance which is probably an imidazole of the following constitution—



—1:2:4-Metaxylidine-6-sulphonic acid, by H. E. Armstrong and L. P. Wilson. In accordance with the views previously published by Armstrong, it is found that although excess of fuming sulphuric acid converts 1:2:4-metaxylidine into the 5-sulphonic acid, the 6-sulphonic acid is readily obtainable by heating the sulphate of the base.—The preparation of acetylchloraminobenzene and related compounds, by F. D. Chattaway and K. J. P. Orton.

Geological Society, December 19, 1900.—J. J. H. Teall, F.R.S., President, in the chair.—On the igneous rocks associated with the Cambrian beds of the Malvern Hills, by Prof. T. T. Groom. The Cambrian beds of the Southern Malverns are associated with a series of igneous rocks which have commonly been regarded as volcanic, but are probably all intrusive. They consist of a series of bosses, dykes, sills and small laccolites intruded into the Upper Cambrian Shales and into the Hollybush Sandstone. The dykes appear to be confined to the sandstones, the sills and laccolites chiefly to the shales, while the bosses are found in both. All the rocks have a local stamp, but are probably most nearly related to the camptonitic rocks of the Central English Midlands. Intrusion took place at a period not earlier than the Tremadoc, and probably not later than that of the May Hill Sandstone.—On the Upper Greensand and Chloritic Marl of Mere and Maiden Bradley in Wiltshire, by A. J. Jukes-Browne and John Scanes. The district dealt with is on the borders of Wiltshire and Somerset. The general succession is as follows, the numbers being given in feet:—Lower Chalk, with Chloritic Marl at the base, 200; sands with calcareous concretions, 3 to 8; sands with siliceous concretions (cherts), 20 to 24; Coarse Greensand, 15; fine grey and buff sands, about 120; sandy marlstone, 15; grey marl and clay (Gault), 90.

Royal Microscopical Society, December 19, 1900.—Mr. Wm. Carruthers, F.R.S., President, in the chair.—Mr. Barton exhibited some new forms of lanterns which could be used for ordinary projection purposes either with or without the microscope. The first was a lantern constructed so as to exclude all light from the room except what passed through the lenses; the manner of using this in connection with a microscope was shown. Another lantern exhibited was larger and more complete, and could be used for all purposes, including enlargements. The excellent definition of this lantern was demonstrated by the exhibition on the screen of photomicrographs of mounted preparations of insects, and of whole insects mounted in balsam. Mr. Barton also exhibited and described several new forms of microscope, with detachable circular stage, &c., and a new form of electric arc lamp for lantern use. A new form of lime-light was also exhibited of great brilliancy, steadiness and silence. Mr. Nelson said he was very much struck with the perfection to which the last-mentioned lamp had been brought, and inquired if the gases had been enriched in any way, and how the light was produced with such complete absence of noise. Mr. Barton said nothing was used but the two gases, and the effect was produced by causing them to impinge upon each other previous to their entrance to the mixing chamber, and by the construction of the chamber itself.

MANCHESTER.

Literary and Philosophical Society, January 8.—Prof. Horace Lamb, F.R.S., President, in the chair.—A discussion was introduced by Mr. W. H. Johnson upon the method of navigation employed by the Norsemen on their voyages between Northern Europe and Greenland and Iceland before the mariner's compass was known. Mr. W. E. Hoyle communicated a note on D'Orbigny's figure of *Onychoteuthis dussumieri*, in which he pointed out the resemblance which it bore to a species of Loligo in the Hamburg Museum. The skin of this specimen was partly covered by convex tubercles, giving it a shagreen-like appearance, which was due to its having undergone partial maceration in the stomach of some cetacean. It was further shown that this appearance might perhaps explain the true nature of a cephalopod described by Prof. Joubin, which he stated to be covered with scales resembling those of a ganoid fish. Dr. Lönnberg had found a similar appearance in a specimen of Onychoteuthis from Magellan's Straits, which on investigation proved not to be due to scales at all, but to a swelling of subcutaneous papillæ in consequence of the maceration to which the animal had been subjected. It seemed, therefore, a reasonable hypothesis that all these scalelike appearances were due to a similar cause.

EDINBURGH.

Mathematical Society, January 11.—Mr. Geo. Duthie, Vice-President, in the chair.—Prof. Allardice read a paper on the nine-point conic, and notes were given by Prof. Steggall, Mr. D. B. Mair and Prof. Jack.

PARIS.

Academy of Sciences, January 7.—M. Fouqué in the chair.—M. Bouquet de la Grye was elected Vice-President for the year 1901.—M. Maurice Lévy, the retiring President, announced the changes in the members and correspondents for the past year.—The President announced the death of Dr. Potain, member in the section of Medicine and Surgery.—On the integrals of total differentials of the third species in the theory of algebraic functions of two variables, by M. Émile Picard.—Observations of the comet 1900*c* (Giacobini), made at the Observatory of Algiers, by MM. Rambaud and Sy. The observations, which were made with the 31·8 cm. equatorial on the nights of December 26 and 27, 1900, show that the comet is a nebulosity of 1′ to 2′ diameter with a feeble central nucleus comparable in intensity with a star of the 13th magnitude.—Observations of the comet 1900*c* (Giacobini) made with the equatorial of the Observatory of Besançon, by M. P. Chofardet. The observations were made on December 25, 1900, and show the comet as a rounded nebula without a tail, with a central stellar nucleus of about the 12th magnitude.—On convex closed surfaces, by M. H. Minkowski.—On the theorem of active forces, by M. H. Duport.—On linear equations with indeterminate points, by M. Ludwig Schlesinger.—On the theory of the equations of mathematical physics, by M. S. Zaremba.—On the absolute value of the magnetic elements on

January 1, by M. Th. Moureaux. The absolute values of the magnetic elements is given for four stations, Parc Saint-Maur, Nice, Perpignan and Val Joyeux. The removal of the magnetic instruments to this last station from Parc Saint-Maur was rendered necessary during the year by the increasing disturbances caused by the development of the electrical tramway system of Paris.—On a new phosphide of tungsten, by M. Ed. Defacqz. All attempts to prepare the tungsten phosphide, WP, at the temperature of the electric furnace were unsuccessful, owing to the fact that at the temperature of boiling copper phosphide the tungsten phosphide is dissociated. By working at the highest attainable temperature of a wind furnace, however, in presence of a large excess of copper phosphide, a well crystallised phosphide was obtained having the composition WP. This forms prismatic crystals of a grey metallic lustre, density 8·5, not attacked by air at the ordinary temperature, but converted into tungstic acid at a red heat.—On some properties of sodium peroxide, by M. George F. Jaubert. Sodium peroxide is commonly described as a white substance which deliquesces slowly when exposed to the air. The author now finds that the colour of this substance when prepared in a perfectly pure state is yellow, and further that it does not liquefy when exposed to the air.—Composition of the hydride and nitride of thorium, by MM. C. Matignon and M. Delépine. At a dull red heat metallic thorium burns in a current of hydrogen forming the hydride ThH. With nitrogen, if the metal be heated somewhat more strongly, the nitride Th_3N_4 is formed, which is rapidly decomposed by hot water with the formation of thoria and ammonia.—Some new reactions of the organo-metallic derivatives, by M. E. E. Blaise. A description of a new general method for the preparation of ketones and ketonic acids. The reagent used is the alkyl magnesium iodide obtained by the action of magnesium upon an alkyl iodide, and this is allowed to react with either a nitrile or an isocyanic ester. Thus in this way the author has obtained propionoacetic ester from cyanacetic ester, diethyl ketone from cyanogen, and substituted anilides from phenyl isocyanate.—Action of methyl-acetylacetone and ethyl-acetylacetone on the diazoic chlorides, by M. G. Favrel. The diazo-chlorides react with methyl- or ethyl-acetylacetone with the elimination of a molecule of acetic acid and formation of a hydrazone. This reaction resembles that of the cyanacetic esters containing substituted acid radicles, and also the reaction between the alkyl-acetylacetic esters and diazobenzene chloride.—On the embryology of *Taenia serrata*, by M. G. Saint-Remy. The author gives reasons for believing that the description given by van Beneden of the young egg, not segmented, is not quite exact, and that this description belongs in reality to a slightly more advanced stage.—On the discovery of an origin of the Swiss Pre-alps, by M. Maurice Lugeon.

DIARY OF SOCIETIES.

THURSDAY, JANUARY 17.

ROYAL SOCIETY, at 4.30.—Total Eclipse of the Sun, January 22, 1898. Observations at Viziadrug. Part IV. The Prismatic Cameras: Sir N. Lockyer, K.C.B., F.R.S.—Wave-length Determinations and General Results obtained from a Detailed Examination of Spectra photographed at the Solar Eclipse of January 22, 1898: J. Evershed.—The Thermo-Chemistry of the Alloys of Copper and Zinc: T. J. Baker.

ROYAL INSTITUTION, at 3.—The Origin of Vertebrate Animals: Dr. Arthur Willey.

SOCIETY OF ARTS (Indian Section), at 4.30.—Metalliferous Mining in India: Dr. John W. Evans.

LINNEAN SOCIETY, at 8.—On the Affinities of *Aelurop̄us melanoleucus*, Prof. E. Ray Lankester, F.R.S., with a Description of the Skull and some of the Limb-bones: R. Lydekker, F.R.S.—On the Natural History and Artificial Cultivation of the Pearl Oyster: Dr. H. Lyster Jameson.

CHEMICAL SOCIETY, at 8.—The Preparation of Esters from other Esters of the same Acid: T. S. Patterson and Cyril Dickinson.—Tecomin: a Colouring Matter derived from *Bignonia tecoma*: T. H. Lee.—A New Method for the Measurement of Ionic Velocities in Aqueous Solution: B. D. Steele.—Metal-Ammonia Compounds in Aqueous Solution. II. The Absorptive Powers of Dilute Solutions of Salts of the Alkali Metals: H. M. Dawson and J. McCrae.

FRIDAY, JANUARY 18.

ROYAL INSTITUTION, at 9.—Gases at the Beginning and End of the Century: Prof. J. Dewar, F.R.S.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—Annual General Meeting.—*Possible* discussion upon Mr. H. A. Humphrey's paper on Power Gas and Large Gas-Engines for Central Stations.

MONDAY, JANUARY 21.

VICTORIA INSTITUTE, at 4.30.—Evolution: Rev. G. F. Whidborne.

TUESDAY, JANUARY 22.

ROYAL INSTITUTION, at 3.—Practical Mechanics: Prof. J. A. Ewing, F.R.S.

ANTHROPOLOGICAL INSTITUTE, at 8.30.—On Malay Metal-working (illustrated by Lantern Slides and Experiments): W. Rosenhain.—Slides illustrative of the damage to Stonehenge will also be shown.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Present Condition and Prospects of the Panama Canal Works: J. T. Ford.

MINERALOGICAL SOCIETY, at 8.—Note on an Occurrence of Mirabilite: Dr. Trechmann.—On a Question relative to Extinction-Angles in Rock-Slices: Mr. Harker.—On the Arrangement of the Chemical Atoms in Calc Spar and in some other Crystals: Mr. Barlow.

ROYAL PHOTOGRAPHIC SOCIETY, at 8.—Imitative *versus* Creative (a Comparison): W. Edwin Tindall.

WEDNESDAY, JANUARY 23.

GEOLOGICAL SOCIETY, at 8.—The Glacial Geology of Victoria, Australia: Prof. J. W. Gregory.—The Origin of the Dunmail Raise (Lake District): R. D. Oldham.

THURSDAY, JANUARY 24.

ROYAL SOCIETY, at 4.30.—*Probable* papers: The Boiling Point of Liquid Hydrogen, determined by Hydrogen and Helium Gas Thermometers: Prof. J. Dewar, F.R.S.—Investigations on the Abnormal Outgrowths or Intumescences on *Hibiscus vitifolius*, Linn.: a Study in Experimental Plant Pathology: Miss Elizabeth Dale.—On the Proteid Reaction of Adamkiewicz, with Contributions to the Chemistry of Glyoxylic Acid: F. Gowland Hopkins and S. W. Cole.

ROYAL INSTITUTION, at 3.—Origin of Vertebrate Animals: Dr. Arthur Willey.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Adjourned Discussion: Capacity in Alternate Current Working: W. M. Mordey.

FRIDAY, JANUARY 25.

PHYSICAL SOCIETY, at 5.—The New Physical Laboratories of the Royal College of Science: Prof. A. W. Rücker, Sec.R.S.—Note on an Absolute Method for determining the Hygrometric State of the Atmosphere: E. B. H. Wade.—Exhibition of an Experiment on the Migration of the Ions: S. W. J. Smith.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Sewage Treatment: C. Johnston.

SATURDAY, JANUARY 26.

THE DEATH OF THE QUEEN.

NOT only the British Empire, but the whole world is mourning the death of one of the most beneficent Sovereigns who has ever adorned a throne. History will for many centuries record the fact that her long reign has been contemporaneous with the most tremendous advances of science which the world has so far seen. In consequence of one of these advances, the civilised communities spread over the whole surface of the planet have mourned simultaneously, and as with one voice, the loss of one universally beloved.

But besides the advances in pure science which have characterised the reign, and the applications of it to the amelioration of human ills and to the greater well-being of humanity, there has been progress along other lines which have been largely dependent upon the Queen's own perfect life and character; her efforts to keep the world's peace, and her intense anxiety that the well-being of even the humblest of her subjects should be fully cared for.

Thanks to all these causes, constantly at work, her glorious reign has possessed a special characteristic, and it has been well called the Victorian age.

What we owe to the circumstances of the time, and Her Majesty's unceasing efforts to mould them for the nation's good, has been well stated in the *Times*.

"Her reign coincides very accurately with a sort of second renaissance, an intellectual movement accomplishing in a brief term more than had been done in preceding centuries. Since the days of Elizabeth there has been no such awakening of the mind of the nation, no such remarkable stride in the path of progress, no such spreading abroad of the British race and British rule over the world at large, as in the period covered by the reign whose end we now have to deplore. In art, in letters, in music, in science, in religion, and, above all, in the moral and material advancement of the mass of the nation, the Victorian age has been a time of extraordinary activity."

To mention these facts is sufficient to recall the increased national activities, along these several lines, not long after Her Majesty began her reign, when she had by her side the late Prince Consort, to whom the nation owed the idea of the Exhibition of 1851 and everything which flowed from it. His wide culture and complete training enabled him to foresee then (that is, half a century ago) what very few of our statesmen recognise now, that brains and complete mastery of all the arts of peace are the most stable bases of a nation's greatness.

Few young rulers were so happy as the Queen in her family life until the lamented death of the Prince Consort—one of the best friends that the English nation has ever had. It was largely owing to his wise foresight and influence that the improvement of our British system of education was undertaken; and in 1852, in the Speech from the Throne, Her Majesty spoke as follows:—

"The advancement of the Fine Arts and of practical Science will be readily recognised by you as worthy the attention of a great and enlightened nation. I have directed that a comprehensive scheme shall be laid before you, having in view the promotion of these objects, towards which I invite your aid and co-operation."

The death of Prince Albert in 1861 was a blow rom which Her Majesty may be said to have never recovered. It was also a blow to British science which the nation still feels.

The late Lord Playfair told the story how Her Majesty, not long after the commencement of her reign, expressed her desire to show, by distinctions conferred upon them, that she regarded men of science as fellow-workers for the nation's good. He also told us how it came about that at the time this desire was not carried into effect. But during recent years Her Majesty from time to time has shown in this way her interest in scientific progress, and the position of science in the national regard is vastly different to-day from what it was on Her Majesty's accession.

The world is all the poorer for the departure from us of our noble Queen. The nation is stunned: each of her late subjects is mourning a personal loss, but that does not prevent a universal sympathy with those near the throne who, as children or grandchildren, stood at the bedside at so great a passing.

The Royal Family may rest assured that, among the millions of mourners for the loss of one who was truly the Beloved and Revered Mother to all her subjects all over the world, there are none whose sympathy is deeper or more respectful than that felt by the students of science throughout the Empire.

EDITOR.

AN ALPINE CRUST-BASIN.

1: *Das geotektonische Problem der Glarner Alpen.* A. Rothpletz. Pp. vii+251, and Atlas. (Jena: Fischer, 1898.)

2: *Geologische Alpenforschungen.* A. Rothpletz. I. Pp. viii+176. (Munich: J. Lindauersche, 1900.)

A MORE than ordinary interest attaches to these two works by Prof. Rothpletz, as they treat of the boundary district between the Eastern and Western Alps. This district is already famous in geology, and has attracted all comers by its problems. My own opinion regarding its structure had been formed while I wrote my paper on the "Torsion-structure of the Dolomites" in 1898, and was given by me at the British Association Meeting and at the International Geographical Congress in 1899. I then compared the structure of this district with that of the areas of inthrow of various sizes that I had studied in the Dolomites. I described the Glarus-Prättigau area as a local area of depression or crust-basin within the Alps, around which fold-arcs had formed peripherally. Thrust-masses, taking origin in the peripheral arches, had moved towards the centre of the basin. And as across this area of depression the Alpine wave-movement of compression had also passed, the leading strike-curve of the Alps had been superinduced upon the local curves, making various angles with those, so that the actual crust-forms now presented to us were resultant combinations of the local movements round the subordinate basin, with the more extended Alpine movements round the North Italian crust-basins.

Our knowledge of the geology of this district has been vastly extended by Prof. Rothpletz. The actual observations recorded in these works, the discovery of many leading fossils in rocks whose age had hitherto remained doubtful or been erroneously determined, the large number of geological sections and the geological maps, must be regarded as one of the most brilliant achievements in Alpine geology. Two gems of detailed geological mapping may be recommended for careful study, namely, the north-west part of the Glarus district and the fault-blocks of the Rhätikon: (1: Taf. xi., and pp. 166–185; 2: Taf. i., and pp. 69–90.)

In all the leading text-books, the plication of the Alps is referred to lateral compression having acted mainly from the south in the Eastern Alps and rather more from south-east in the Western Alps, hence the curvature of the Alpine strike. Overthrusts are said to have taken place chiefly towards the north on the north side of the central chain, and towards the south on the south side. Glarus, on the north of the central chain, offered an exception to this rule, as according to Prof. Heim's epoch-making work ("Mechanismus der Gebirge," 1878) there had been within Glarus the advance of overthrust masses both from the north and from the south during the last Alpine upheaval.

Prof. Rothpletz contended (1) the existence of an overthrust mass in the south of Glarus, and (2) the correctness of Prof. Heim's conception of a crushed "middle-limb," as theoretically necessary in the process of overthrusting Prof. Rothpletz advocated that the phenomena of overthrusts were akin to differential movements between fault-blocks ("Querschnitt durch die Ost-Alpen," 1894, and "Geotektonische Probleme," 1895). Prof. Rothpletz, in his latest work on Glarus, in 1898, recognises the presence of a thrust-mass in the south of the Glarus area, but treats it as a mass originally continuous with the large thrust-mass on the north (*cf.* p. 211), and concludes from his observations that the whole of this "Glarus thrust-mass" had travelled *from east to west*, a distance of about twenty-five miles from the Rhine valley to the Linth. The rocks that form the *base* of the thrust-plane comprise all the geological horizons from the older gneiss to Oligocene strata, and have been folded along a *curved* strike, east-west near the Linth Valley, but curving round a southern arc to N.E.–S.W. direction nearer the Rhine Valley.

In the south or "Vorderrhein" portion of the "Glarus thrust-mass" the prevailing strike is N.E.–S.W. In the northern portion the rocks of the thrust-mass are folded along a curved strike, curving from S.S.W.–N.N.E. in the vicinity of the Linth Valley round a northern arc to an east-west strike.

In both the basal mass and the overthrust mass the folds have been overcast to the north and north-west, the compression of the folds having been very much stronger in the south than in the north. As many as ten folds overlie one another in the basal mass at Brigelser Horn, and are surmounted by a twisted portion of the thrust-mass with strike veering from S.W.–N.E. to S.N. This curvature is explained by Prof. Rothpletz as probably due to the local resistance offered by two eruptive masses (p. 160).

Three higher tiers of thrust-masses are present on the west of the Linth Valley in the Glärnisch Mountain; two of these thrust-masses continue in curved direction north-eastward to the Schild Mountain and Lake Walen. The names given to them by Prof. Rothpletz are the Schild, Urner and Schwyz thrust-masses. Prof. Rothpletz says these masses have travelled from the north-west, but he expressly states his opinion that they advanced subsequently to one another and subsequently to the advance of the Glarus mass from the east, or locally south-east (p. 216).

Looking now at the second work, which treats of the east side of the Rhine Valley, the most important result is the description of a Rhätikon and Silvretta overthrust from the east. Prof. Rothpletz proves that the rocks of the Rhätikon Chain rest on a basal mass which is the natural continuation of the Glarus thrust-mass eastward, and he concludes that the Rhätikon mountain mass travelled from the Montafon Valley to the Rhine Valley, about nineteen miles from east to west. Tracing the origin of this thrust southward, he finds the rocks of the Silvretta Massive have been thrust eastward above the basal mass of the Prättigau, and still farther south the overthrusts are continued in the Lenz and Oberhalbstein mountain-group. The independence of the over-thrusting and the folding processes may, in Prof. Rothpletz's opinion, be concluded from the fact that the direction which has been followed by the thrust-mass frequently makes an angle with the strike of the folds. He attributes the difficulties which have hitherto attended the solution of the geological problems here:—

(1) Partly to the fact that all these overthrust masses and the basal mass in the district of the Glarus and Rhätikon have been pushed subsequently towards the north-west above the folds in the outer, or "molasse," zone of the Alps; thereby the original inclinations of the several thrust-planes have been altered or masked. (2) Partly to subsequent displacements effected along longitudinal and transverse fault-lines. (3) Partly also to the insufficient knowledge of the details of the stratigraphical succession as exhibited in the different facies of the Helvetic and the Austrian Alps.

What occurs to me in reading these works is that a great number of the observations which Prof. Rothpletz has given are unaccounted for in the conception of the structure as yet presented by that author. The conception does not go far enough, it misses the significance of the author's carefully collected data of strike and dip which prove intercrossing and curved strikes to be really the leading structural feature of the district. Prof. Rothpletz does not offer any explanation of that remarkable fault-curve in his map which follows the Linth Valley N.N.E. as far as the Schild Mountain, then curves east to the Sees Valley, and again S.S.E. and S.E. to Sargans; or interpret that other zig-zagging fault which curves round the south of the Rhätikon and south-east through the Falknis Chain, then southward in the Silvretta Massive, and again south-west through the Lenzerhorn Chain. According to my experience in the Dolomites, and having regard to the variations of the strike in the folds of the thrust-masses, I would consider these as primarily strike-faults through curved folds that formed round a local crust-basin (*cf. Geological Magazine*, 1894, pp. 54-58; *Q.J.G.S.*, 1899; *Geographical Journal*, 1900).

Let any one glance at my figure of the torsion-curves round the northern periphery of the Adriatic crust-basin (*L.C.*, 1899, fig. 22). The curves are convex to the north; the chief overthrusts have come from the W.N.W., N.W., N. and N.E., and have moved centripetally with reference to a centre in the Adriatic depression. Or compare the much smaller fold-arc of the Gröden Pass arch and its accompanying fault-curve from Plon over the Gröden Pass to Ruon and Corvara.

The arc of origin of the thrust is convex to the north; the thrust-mass has advanced southward and been broken up into several fault-blocks by faults, for the most part, transverse to the arc of origin. Return, now, to the map of the Glarus (Rothpletz's Atlas, Taf. xi.), and it will be clear that there is a repetition of similar geological phenomena. Even the details in the typical fold-forms are essentially alike (compare Rothpletz, Plate v., Figs. 5, 6, with sections 4, 5, 6 and 16, 17 in my "Torsion-structure.") In passing, it may be said that this similarity is in so far important, as it shows how much closer is the resemblance in the structure of the Eastern and Western Alps than has been usually supposed.

My interpretation of Prof. Rothpletz's data may now be indicated. His description of the continuation of the Glarus thrust-mass westward and eastward from the Mürtschen-Stock shows that it is broken by numerous faults along which both horizontal and vertical displacements have taken place, and that the typical fold-form has undergone quite different modes and degrees of compression in the several fault-blocks. From the Firz Stock in the east to the Linth Valley in the west one is presented with a series of uplifts and downthrows having the character of incipient folds, where arches and troughs are limited by steep septa or faults. The Mürtschen and Firz group is buckled into three main fault-blocks, the central of which is the highest, while the Schild group is depressed relatively to the eastern group, but within itself shows also a central upthrow flanked by downthrown blocks. The faults which have determined this cross-buckling are practically transverse to the local curvature of the strike. They therefore represent what I termed "radial" faults, or the fault-radii of a fold-arc (*Q.J.G.S.*, 1899, p. 604). This cross-blocking of a fold-arc demonstrates the action of horizontal pressures parallel with the direction of the curved strike, in addition to the action of horizontal pressures rectangularly to the fold-arc, and indicates that we have here *a system of local pressures complete in itself.*

I further note from Prof. Rothpletz's sections that the horizontal compression along N.W.-S.E. lines has been much stronger in the case of the Schild group than in that of the Mürtschen group (1: Taf. vii., Figs. 8, 15). The N.W.-S.E. strike represents the general Alpine strike at this part of the Alps, and it will be observed that in the Schild area the "Alpine" strike coincides, or is very slightly oblique, with the local strike, hence the resultant crust-deformation here represents the sum of two almost similarly-acting sets of pressures. Moreover, it is well known that the Alpine movements became rapidly less intense from west to east in this boundary district between the Western and Eastern Alps. The predominance of the N.E.-S.W. or "Alpine" strike in the basal mass of plastic strata, and the general overcasting to N. and N.W. of the folds, both in the basal mass and the thrust-mass, together with oblique overthrusting between the fault-blocks, seem to me conclusive evidence that the "Alpine" movements were not only subsequent to the formation of the fold-arcs, but also subsequent to the initiation of the N.N.W.-S.S.E. faults through the fold-arc (*cf.* footnote, *Q.J.G.S.*, 1899, p. 559).

Take, again, the Rhätikon thrust-mass in Prof. Rothpletz's map (2, p. 161). Faults virgate from Bludenz to W.S.W. and S.W., and cut the curved fault which separates the Rhätikon and the Falknis crust-blocks. These faults I take to have been originally fault-radii of a Rhätikon fold-arc formed round the north-east of the crust-basin. The overthrust of that mass has taken place in the main *from* this direction towards the south-west. Each fault-block in this thrust-mass is gently folded between the Montafon Valley and the Falknis, and a N.W.-S.E. strike is present in the Gorvion and other parts close to the Falknis Chain. This strike, together with the folding, indicates the action of horizontal pressures from the north-east; and the virgating group of faults across the Rhätikon indicates the action of horizontal strains parallel with the curved strike of the fold-arc, effecting transverse fractures in the sense of fault-radii of the arc. Hence there is in the Rhätikon evidence of a complete set of local phenomena of compression

analogous in character to those which appear in the north-west portion of the Glarus-Prättigau crust-basin.

The Falknis block is an anticlinal block separated by curved strike-faults from the Rhätikon on the north and he Prättigau on the south, and cut by north-south faults. It shows, therefore, the general east-west strike and transverse fractures characteristic of the eastern Alps. The curvature of the strike in the west part of the Falknis Chain from east-west to north-west may, like the curvature of the fault at this part, be taken to signify a resultant or compensatory divergence due to the inter-crossing of the local and the east-Alpine strike. Similarly, at the east end of the Falknis, the east-west strike curves to the south-east. The Falknis fault-block is a replica of the Gröden Pass anticlinal fault-block. The east-west strike is the dominant strike of the Eastern Alps, trending to E.S.E. in South Tyrol. It is acknowledged to have been an ancient strike along which movements have recurred in various ages in the Eastern Alps, although during the Pliocene movement the horizontal compressions from north and south were much less intense in the eastern than in the western Alps. This fact expresses the chief difference which obtains between the structures on the east and the west of the Rhine Valley. The fold-arcs round the east of the Glarus-Prättigau crust-basin have not sustained the same degree of compression during the subsequent Alpine folding as those round the western periphery; neither have the horizontal pressures acted quite from the same directions, the Alpine pressures having acted across Glarus towards the N.W., and across the Prättigau and Rhätikon more towards the north.

The eastern thrust from the Silvretta Massive gives expression both to the horizontal compressions rectangular to the eastern fold-arc of the local crust-basin, and to the horizontal strains acting along the strike of the Alpine curve. In the greater Alpine curve, just as in the case of the smaller curve of the local basin, the formation of radial uplifts and downthrows is determined by these tangential pressures. And it is this cross-system which is more particularly accountable for the diagonal N.N.W. and N.N.E. and transverse faults and thrust-fractures in the Alps.

In my interpretation the Lenzerhorn Chain represents fold-arcs on the south-east of the local basin. The curved strike veers here from north-east to west, and there are also fault-radii in N.N.W. direction. The oblique shearing that has occurred here is apparently stronger than in the Rhätikon, but not nearly so strong as in the Brigels and Vorderrhein Chain, which represents the southern fold-arc in the Glarus district. My inference is that the original Glarus-Prättigau crust-basin with its peripheral folds has been cut into two unequal halves by the development of the Rhine fracture during the later Alpine movements. The Rhätikon and the Glarus have been rent asunder at the north of a radial Alpine fracture. The regional Alpine movements have superinduced wider curves above the local curves and have affected the two halves of the basin with different degrees of intensity, so that the eastern half occupies a broader area from north to south than the more strongly crumpled western half.

Hence the ground-work of the structure in this region is based upon *intersecting fold-arcs*, and all the additional details supplied by Prof. Rothpletz can be adopted in the scheme of Alpine geology which I demonstrated in 1899 upon the basis of the "fold-arc" and the "unit-area of depression" surrounded by torsion-curves of strike (Report Intern. Geogr. Congr. Berlin, 1899). The science of geology finds itself, at the threshhold of this new century, entering upon a development of research in which advance can only be made if the student of earth-structures can bring to bear upon his observations a sound knowledge of the laws of higher mathematics, dynamics and physics. And, if I may make a forecast, it is that structural geology will be ere long grouped in our university curricula with these exact branches of science.

MARIA M. OGILVIE-GORDON.

THE ZOOLOGICAL RECORD FOR 1899.

The Zoological Record. Vol. xxxvi. Being Records of Zoological Literature Relating Chiefly to the year 1899. Edited by D. Sharp. (London: Gurney and Jackson, 1900.) Printed for the Zoological Society.

THE editor of this invaluable record is to be congratulated on its early issue, the present volume having been in the hands of the public during the first week in December. The amount of energy on his part necessary, in order to secure punctuality in the delivery of their quota of manuscript from twelve contributors, can scarcely be realised except by those who have undergone a similar experience. This early appearance of the volume is, however, in part due to the circumstance that the contributors are now instructed not to await the arrival of the whole of the year's literature, but to be content with as much as is to hand at the date when their manuscript is required. That this decision is a wise one there can be no doubt, for it is much more important to issue the record at as early a date as practicable, than it is to insist on its containing the whole available literature of the year to which it is specially devoted.

This leads naturally to the remark that some want of uniformity is noticeable with regard to the inclusion of portions of certain serials in each year's record. For instance, the fourth part of the volume of the *Proceedings* of the Zoological Society of London for each year is not issued till well on in the following year. Now we find that in the records of mammals and birds, the contents of this part are quoted in the year to which they nominally belong, while they are omitted in the reptile and fish records. It is not for us to discuss which plan is the better, but we do urge that strict uniformity in this respect should be insisted upon by the editor.

Nor is this the only instance in which that functionary does not appear to have his team sufficiently well in hand. As the record of insects is by the editor himself, we may take this as the model which ought to be strictly followed by all his subordinates. This record is preceded by a carefully written introduction, bringing into special notice the leading features in the year's work; the papers are numbered, and where a series of new species are described in any particular genus, they are collectively designated as such at the end of the paragraph. In the

main, this admirable model is copied in the mammal record; but in the bird section the introductory notice is confined to five lines, and the number of unnecessary repetitions of "n. sp." (as on page 38) wastes much valuable space. In the reptile and fish records no introduction at all is given, and the papers are not numbered. Introductions are likewise wanting to the Bryozoa and Cœlenterata records. On the other hand, in the Tunicate record the notices of work accomplished are, compared with other sections, disproportionately long and too verbose.

Again, there are many minute details where more supervision on the part of the editor might, we think, have been devisable. For example, some recorders use "P. Z. S.," and others "P. Zool. Soc., London," for a familiar zoological journal. In the case of another journal we find it abbreviated to "P. New England Zool. Club" in the editorial list at the commencement of the volume; but in the mammal record (p. 4) it is quoted as "P. New England Club"; and in the bird record (p. 39) as "New England Zool. Club." Again, on p. 4 of the reptile record we find the abbreviation "Bull. Philad. Mus.," for which there is no corresponding entry in the serial list.

As an example of another type of what we venture to call lack of smartness, it may be noticed that on p. 38 of the bird record the entry relating to temperature should have come under the heading of Ratitæ instead of under one of the subdivisions of the same; and a similar remark applies to the second entry under the heading Accipitriformes, on p. 47. Again, on p. 39 of the same record, we fail to see why initials are prefixed to some authors' names and not to others; and why a well-known ornithologist is alluded to in one line as W.R. Ogilvie Grant and a few lines later on simply as Grant. In our opinion, such initials, except when there are two authors of the same name, should always be omitted, whereby much space would be saved. But here, as elsewhere, we crave above all things for rigid uniformity, which, in our opinion, should be made a *sine quâ non* by the editor.

We should also think it an advantage if it were definitely decided whether reviews of papers are to be included in the record. Such reviews are quoted in the Echinoderm record, but are omitted in the majority of the others. And here we may take the opportunity of inquiring why the names of authors in the Echinoderm record are printed in much larger type than in the other sections of the volume. Much valuable space is also wasted in this record by the very unnecessary multiplication of paragraphs. Catalogue numbers are also added to the papers, which is not done elsewhere.

Turning from the unpleasant task of fault-finding to the more congenial duty of commendation, it may be said that, apart from trivial errors and what we regard as imperfections, the work on the whole has been carried out in a most excellent manner alike by the editor and his contributors. With the aid of the admirable subject-index which has been introduced of late years by Dr. Sharp in each record it is now practicable for a worker in any special branch of morphology—say histology of the eye—to find out what has been done in that particular subject in each group of the animal kingdom. The record of new species and sub-species seems to be as well kept as in previous years, and at present shows no signs of diminution in length. Of course there are some omissions which ought not to have occurred—notably one of a so-called new species of reindeer by the mammalian recorder; but these, it is to be hoped, will be filled up in the next year's issue.

And here it may be remarked that it is a great pity that certain scientific bodies are so dilatory in despatching their publications. For instance, the library of the Natural History Branch of the British Museum, on which so many of the contributors to the *Record* depend for their material, only received in November last certain parts of the *Bulletin* of the Paris Museum which were issued in 1899. Consequently the names of several species of mammals published during the year do not appear in the present volume, and similar omissions not improbably occur in other groups.

A feature of Dr. Sharp's insect record is the inclusion of an obituary list. There is no doubt that such a list is frequently very useful, but if a separate one were made for each division of the record a very unnecessary repetition of names would occur, and there would be some names whose position it would be difficult to allocate. A preferable plan, we think, would be to give a general obituary list, indicating the special subject or subjects connected with each name by appropriate letters.

We believe ourselves justified in saying that the Council of the Zoological Society have resolved to continue the issue of the *Record* for at least another year; and although to some it may appear an unnecessary expenditure of time and money to do work twice over, the convenience of having a special record of zoological work is so great that the apparent waste of energy may be justified.

As one who has worked for some years under Dr. Sharp's supervision, the writer of this review may take the opportunity of acknowledging the extreme lightness of the pressure of the editorial yoke, and the courtesy with which his own suggestions or objections have always been received.

R. L.

OUR BOOK SHELF.

Practical Lessons in Metal Turning. By Percival Marshall. Pp. 166. (London: Dawbarn and Ward, Ltd., no date). Price 2*s.* net.

OF all the different trades included in the term "mechanical engineering," that of the turner is probably as interesting as any, and seems to appeal to the amateur mechanic rather more than the others, for, given an efficient foot lathe, the work done is of general interest.

The book under notice will be found to contain information of much value to the happy possessor of a lathe, more particularly to the apprentice or amateur in the early stages of learning his trade; and in dealing with his subject the author prefers to devote the space at his disposal to a description of how a lathe is worked, rather than to how it is made.

The various processes are clearly dealt with in nine chapters, commencing with the important question of cutting tools with their proper angles for clearance, cutting and top-rake when working various materials We note, however, that the question of cutting speeds appears to have been overlooked, and this is unfortunate because it leaves the apprentice or amateur very much in the dark at the very beginning. Further on, measuring appliances are dealt with. More should have been made of micrometer callipers, so largely used in the States. These are not even illustrated.

On chucks and mandrils our author has much to say, and useful advice is given on how to centre work for the lathe, the book concluding with a chapter on screw-cutting of a rudimentary nature, sufficient, however, to give the amateur a good start in this somewhat difficult subject.

Taken as a whole, the little book will be of much use to the young apprentice and amateur. It flavours more of the workshop than of the technical school, which is very much in its favour.

Principles of Plant Culture. By Prof. E. S. Goff. Second Edition. Pp. 287. (Wisconsin: Madison. Published by the Author, 1899.)

MANY of our county councils have now instituted training colleges for teachers, and laboratories for the instruction of pupils in the elements of agriculture and horticulture. In such establishments Mr. Goff's little treatise, which is now in a second edition, will be most useful. The phenomena of the life of plants are clearly explained, and the details of internal structure sufficiently set forth. The application of these facts to the practical details of cultivation is shown, and stress laid upon the conditions that are propitious, as well as on those that are adverse, to plants. Numerous illustrations are given and, as an appendix, is provided a syllabus of laboratory work containing directions whereby the pupil may be assisted in realising for himself the teachings of the text.

It is a book suitable not only for those who have the advantage of access to a laboratory, but also for those who have to acquire a knowledge of plant-life without the assistance of a teacher.

Photography in Colours. (Photography Bookshelf, No. 5.) By R. Child Bayley. Pp. 74. (London: Iliffe, Sons and Sturmey, Ltd., 1900.)

THERE are probably many people who wish to obtain a general survey of the different attempts that have been made to solve the fascinating problem of "photography in colours" without necessarily entering deeply, or at all, into the practice of any one or more methods. Every one who practises photography should, however, have an intelligent idea of the various processes in use, even if such knowledge amounts to a mere outline of the principles involved. Until now there has been no book devoted to such a summary, so the one before us is very welcome for filling such a gap in our literature.

The author has naturally avoided all technicalities, and confined himself strictly to the explanation of the fundamental principles on which each method is based. The book, it may be mentioned, originated from the editorial articles written by the author for *Photography*, which have been revised and published in this handy form.

The Romance of the Earth. By A. W. Bickerton. Pp. 181. (London: Swan Sonnenschein & Co., Ltd., 1900.) Price 2*s.* 6*d.*

THIS is an attempt to trace, in a popular manner, the history of the earth from the time it had a separate existence to the present, together with that of its fauna and flora. As giving an idea of the subjects touched upon it may be mentioned that among the titles of the various chapters are "The Beginning of the Earth," "Earth-Sculpturing," "Ice-Ages," "Evolution," "Embryology" and "Organic Ascent." In order to make the story a connected one, the author admits that where facts have not been available he has permitted himself "to speculate, to make deductions from the accepted laws of nature." To this there could be no objection had some clear indication been given whereby the reader might distinguish the generally accepted ideas from the personal views of the author. Still, the book is well written and appropriately illustrated, and provides an interesting first course of reading on some of the greater problems of science.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Directions of Spirals in Horns.

THE direction of the spiral in the horns of Bovidæ is, I think, a less simple matter than might be inferred from Mr. G. Wherry's interesting note in NATURE for January 10, p. 252; at all events so far as sheep and goats are concerned.

The only wild goat with truly spiral horns is the markhor, *Capra falconeri*, in all varieties of which the spiral is, as Mr. Wherry states, "crossed" (right horn twisting to left, left horn to right), but in the great majority of tame goats the reverse is the case, the horns being "homonymous." This was pointed out to me many years ago by the late Edward Blyth, and I have been able to confirm his observations repeatedly in countries where tame goats abound, both in India and in North-East Africa. The rule is not without exceptions, a few tame goats having horns coiled like the wild markhor. I have already called attention to these facts in the "Fauna of British India, Mammalia," p. 508. The "homonymous" spiral in tame goats is the more interesting because it is probable that most of them are derived from the wild *Capra aegagrus*, which has horns curving backwards, not spiral.

As regards sheep, the horns in all the *Ovis ammon* group, including *O. poli*, are "homonymous," as Mr. Wherry says. But the bharal, *Ovis nahura*, has its horns arranged on the reversed or "crossed" system. It is true that the bharal is in some other respects intermediate between sheep and goats.

W. T. BLANFORD.

The "Usefulness" of Science.

IN your interesting article on "The New Century" in the January 3 number of NATURE, I notice that you endorse M. Lévy's account of the usefulness of "useless" studies and even proceed to suggest that "all our progress has come from the study of what was useless at the time it was studied." Now while fully agreeing with your main argument, it seems to me that this goes too far. Certainly M. Lévy's illustrations do not prove it. For it so happens that the early astronomical observations, to which he appeals, so far from being useless in the eyes of those who made them, were believed to be of the utmost practical importance. In fact, it may be doubted whether the study of astronomy has ever again been prosecuted in so directly utilitarian a spirit as in its infancy. For, quite apart from the practical need of determining the succession of the seasons, which M. Lévy seems to have strangely overlooked, it was generally believed that the observation of the heavenly bodies was "useful" as a method of forecasting terrestrial events. Astronomy was the offspring of astrology, and assiduously practised because no distinction had yet been made between those heavenly bodies which made great practical differences to human affairs, like the sun and the moon, and those whose influence was inappreciable. Furthermore, it must be remembered that these same bodies were regarded as literally deities of the highest order, so that their observation was a religious rather than a scientific act. This veneration of the heavenly bodies, moreover, persists throughout Greek science, and even Aristotle regards them as composed of a purer and diviner material than anything "sublunary." So that, when he advocates the "useless" θεωρία of astronomy and mathematics as the highest exercise of human faculty, he does *not* mean "seek knowledge for its own sake," but rather "raise yourself to the contemplation of what is nobler and diviner than anything earthly." For the eternal and immutable truths of mathematics also were regarded as being of more than human validity. Hence it seems a mistake to call these primitive researches useless because we do not happen to believe in the use they were supposed to have.

And this suggests a further scruple. Does not the doctrine that the "useful" discoveries arise out of the study of the "useless" come perilously near to a psychological paradox? For how can any one rationally pursue the study of what he at the time conceives to be useless? It must at least be useful to him, *i.e.* satisfy his desires in some way or other. In the last resort, what can the useful be but that which satisfies some human desire, subserves

some human purpose? In the widest sense, therefore, all knowledge which is desired must be useful in some way and for some purposes, and, even on the most narrowly "utilitarian" interpretation, the useful is nothing else or more than what satisfies desire—except that an attempt is made to restrict it to the satisfaction of a very limited set of desires. An absolutely useless method or study would be one that could not be worked in any conceivable manner or for any conceivable purpose, *i.e.* it would be not merely useless, but *false.* The proper defence, therefore, of the so-called "useless" researches seems to me to consist in showing in the first place that the context of a science requires them, and in the second in pointing out that it has always, so far, proved possible to find a directly practical application for what is organically connected with a system of knowledge.

Corpus Christi College, Oxford. F. C. S. SCHILLER.

The Field-mice and Wrens of St. Kilda and Shetland.

IN his notice of Messrs. A. H. Evans and T. E. Buckley's "Fauna of the Shetlands" (NATURE, May 24, 1900, pp. 75 and 76), your reviewer regrets that the authors are silent in regard to the special characters of the Shetland field-mouse, in view of my own recent recognition of a peculiar representation of this type in St. Kilda. It may be interesting to point out that in a recent paper on geographical and individual variation in *Mus sylvaticus* and its allies (*P.Z.S.*, 1900, p. 387), I found myself unable to separate the Shetland field-mouse (specimens of which I had fortunately been able to examine), at least at present, from that of Great Britain generally. I would not, however, therefore necessarily bind myself to follow your reviewer in his suggestion that the comparative distinctness of the local forms of wren and field-mouse may guide us in forming a decision as to the relative periods during which St. Kilda and the Shetlands have been separated from the mainland. So many factors seem to be brought into play in the evolution of a local race or subspecies that it is, I fear, unsafe to rely too much on such points, and I have a strong suspicion that the influence of the environment has been too little taken into account by recent writers. At all events the field-mouse of Iceland would, it might be thought, show remarkable deviations from the mice of Western Europe, yet the little that we know of it only shows us how closely allied it is to *Mus sylvaticus* proper.

As regards the wrens of Iceland and of the various Scotch islands, attention may be directed to an interesting series of measurements of wings given by Mr. R. M. Barrington in a footnote to p. 641 of his book on "The Migration of Birds as Observed at the Irish Lighthouses and Lightships." These seem to show a gradual diminution in size from the large *Troglodytes borealis* of Iceland through the Shetland wren, which, although smaller than *T. borealis*, seems to be larger than *T. hirtensis* of St. Kilda; the latter exceeds in size the wrens of Ireland. But no doubt intermediates occur, and a wing received from the lighthouse on the Tuskar rock off the Wexford coast in October, 1888, equals that of a specimen from St. Kilda, whence, perhaps, it may have been a migrant.

G. E. H. BARRETT-HAMILTON.

Kilmanock, Arthurstown, Waterford, Ireland.

Sexual Dimorphism.

IF Prof. Meldola does not suppose that all spontaneous variations are limited in inheritance to one sex, he is logically bound to admit that the theory of sexual selection does not explain unisexual inheritance. There can be no possibility of verbal juggle in my arguments, because I define a secondary sexual character as one that is affected by castration, one that does not develop normally after removal of the generative organs, a spontaneous variation as one that is not produced by the conditions of life.

But it is not my theory that "the stimulations which produced a male character necessitate the restriction of that character to the male," and therefore I am not affected by the dilemma in which Prof. Meldola thinks I am placed. On p. 94 of my book will be found these words:—

"It is possible that unisexual characters originally developed by special stimulations related to reproduction, tend sooner or later to be inherited in common by all individuals of the species, that, considered in relation to periods of evolution, their sexual limitation is only temporary."

I fear that Prof. Meldola has not yet sufficiently considered my theory. J. T. CUNNINGHAM.

Penzance, January 11.

THE theory of sexual selection never pretended to *explain* unisexual inheritance. Its author started with a fact:—"Inasmuch as peculiarities often appear under domestication in one sex and become hereditarily attached to that sex, so no doubt it will be under nature" ("Origin of Species," 6th ed. p. 69).[1] Neither does the theory of natural selection pretend to *explain* ordinary, *i.e.* bisexual, inheritance. But Mr. Cunningham pretends that his theory does explain unisexual inheritance, and having in spite of the statement contained in the concluding sentence of the above letter—given very full consideration to his views, I have come to the opposite conclusion. I repeat that his theory does not explain unisexual inheritance.

Mr. Cunningham has now given a further and more restricted "definition" of secondary sexual characters. In this he has not only gone far beyond Darwin, but he has virtually cancelled at least half of his own book. The whole of the evidence that characters developed in one sex are latent in the other was summarised by Darwin in 1868:—"We thus see that in many, probably in all cases, the secondary characters of each sex lie dormant or latent in the opposite sex, ready to be evolved under peculiar circumstances" ("Variation of Animals and Plants," 1st ed. vol. ii. p. 52). All the evidence with regard to secondary sexual characters which Darwin considered in arriving at the above conclusion was based on cases observed in mammals and birds, and, with his well-known caution, he only admits probability in extending it to all cases. But Mr. Cunningham now has converted Darwin's cautiously expressed probability into a "definition"! In doing this he has practically wiped out the whole body of material relating to classes other than mammals and birds which he has brought together in his own work. I confess that I have not of late years been able to follow very closely the progress of knowledge in this direction, but, so far as I know, there is no single observation, with the exception, perhaps, of *Stylopised* bees, which would bring the secondary sexual characters of fishes, reptiles, crustacea, insects, &c., within Mr. Cunningham's definition. Is there any known case among these lower groups where the "removal of the generative organs" (to use Mr. Cunningham's own expression) leads to the appearance of the characters of one sex in individuals of the other sex?

There is another inexplicable statement in the above letter: "It is not my theory that 'the stimulations which produced a male character necessitate the restriction of that character to the male.'" I must again quote Mr. Cunningham's own remark of December 29, 1900. "My theory is that they (the variations) were so limited in development because they were due to stimulations similarly limited" (NATURE, January 10, p. 252). If this does not mean that he is attempting to explain the sexual limitation of characters by "stimulations" applied originally to the sex in which they are now developed, then it appears that he has abandoned his fundamental proposition, viz., that his theory *explains* unisexual inheritance. The restriction of this sexually limited inheritance by considering it temporary instead of permanent, as indicated in the passage quoted by Mr. Cunningham at the conclusion of the above letter, does not affect the argument in any way. We still have to learn how and why the theory of "stimulations" explains unisexual inheritance, even if the latter be only temporary.

I venture to think that editorial hospitality has been sufficiently taxed in connection with this subject. So far as I am concerned I must beg Mr. Cunningham to consider the discussion as closed. The issue is before the readers of these columns, and I do not think that any further advance is likely to be made by mere iteration and reiteration. I consider that indirectly the author of "Sexual Dimorphism" has done excellent service to the cause of Darwinian evolution by enabling us to realise how a well-conceived and well-worked-out application of Lamarckian principles completely breaks down on critical examination. R. MELDOLA.

January 12.

Very Cold Days.

THE following account of days on which the minimum temperature was under 20° (at Greenwich) may be found instructive.

There have been 162 of these very cold days in the last sixty

[1] "We may conclude that one cause, though not the sole cause, of characters being exclusively inherited by one sex, is their development at a late age" ("Descent of Man," &c. 1st ed. vol. i. p. 295). This is the utmost extent of Darwin's application of the evidence in discussing the sexual limitation of certain characters. The explanation is based on the hypothesis of "pangenesis" (*loc. cit.* p. 284).

years; thus averaging about 2·7 days annually. (The annual number of frost days is about 55.)

The year distribution is as follows:—

1841	7	1856	2	1871	3	1886	4
1842	—	1857	—	1872	—	1887	4
1843	—	1858	—	1873	—	1888	3
1844	1	1859	3	1874	3	1889	4
1845	4	1860	3	1875	1	1890	7
1846	3	1861	5	1876	2	1891	6
1847	6	1862	—	1877	—	1892	2
1848	1	1863	—	1878	3	1893	5
1849	2	1864	4	1879	5	1894	5
1850	—	1865	4	1880	5	1895	11
1851	—	1866	—	1881	10	1896	—
1852	—	1867	7	1882	—	1897	—
1853	1	1868	—	1883	—	1898	—
1854	2	1869	—	1884	—	1899	1
1855	14	1870	7	1885	—	1900	2
							162

The greatest number in any one year is 14, in 1855. Next come 1895 with 11, 1881 with 10, four with 7 each, &c. Considering *winters* instead of *years*, the highest number is 12, in 1854–55. On the other hand there are 22 years with none of these days, *i.e.* more than a third of the whole. We do not find more than *four* such years in succession; such a group is presented in 1882–85.

The distribution in months is as follows:—

Jan.	Feb.	Mar.	Nov.	Dec.	
68	42	5	2	45	= 162

Thus, January is *facile princeps*. February and December are nearly equal. The days are rare in March, and most rare in November. Of the two in November, one was on the 30th, in 1856 (19°·4), the other on the 28th, in 1890 (18°·3). The latest in March was on the 14th, in 1845 (13°·1).

Speaking roughly, we seem to have had an increase in those very cold days. Grouping in decades we find this:—

1841–50	1851–60	1861–70	1871–80	1881–90	1891–1900
24	25	27	22	32	32

The first three total 76; the last three 86. To put it otherwise, the thirty consecutive years ending 1895 had more of those days than any other thirty-year group.

Do these days present any definite relation to the sun-spot cycle? I think we may discern (as in the case of frost days) a tendency to greater cold before a maximum of sun-spots than after. This may be variously shown; here *e.g.* is one way:

Compare the group of years from the seventh after a maximum year to the next maximum year (inclusive) with the six years after the latter maximum. We may construct a table as follows:

	a Annual Average.		*b* Annual Average.	Relation *a* to *b*.
1844–48	3·0	1849–54	0·8	+2·2
1855–60	3·7	1861–66	2·2	+1·5
1867–70	3·5	1871–76	1·5	+2·0
1877–83	3·3	1884–89	2·5	+0·8
1890–93	5·0	1894–99	2·8	+2 2
				Av. +1·7

Thus the group of years ending with a maximum year shows an average which is always in excess of that of the six-year group following.

These very cold days are often found in groups. Among the longest are February 16–22, 1855, and February 5–10, 1895.

I may close with a list of the ten coldest days:—

		Min. °
1.	January 9, 1841	4·0
2.	January 5, 1867	6·6
3.	February 8, 1895	6·9
4.	February 12, 1845	7·7
5.	January 4, 1867	7 7
6.	December 25, 1860	8 0
7.	February 7, 1895	9·6
8.	January 8, 1841	9·8
9.	December 25, 1870	9·8
10.	December 29, 1860	10·0

ALEX. B. MACDOWALL.

NATIONAL PHYSICAL LABORATORY.[1]

THE first annual report of the Executive Committee of the laboratory, which was laid before the Royal Society at its annual meeting, is in some respects disappointing. It contains a record of much valuable labour, rendered useless by the opposition to the site on the Old Deer Park at Richmond, which had been selected for the laboratory; while the delays caused by that opposition have made the progress of the scheme very slow.

The Richmond site was chosen by Lord Rayleigh's committee, and approved by the Treasury; the director's first task, after taking up his duties, was to visit the Reichsanstalt and the Bureau International at Sèvres. The courtesy of the authorities of these two institutions is suitably acknowledged in the report, and is another evidence of the international character of science. Meanwhile, in order that the new laboratory might, from the beginning, adapt itself to real wants, various committees had been considering the questions which seemed to press most urgently for solution. With their reports before them, the executive committee prepared plans, and authority was given in June last to obtain tenders for the work. Then followed a delay of some four months. During the summer a deputation from the Royal Society waited on Mr. Hanbury, urging that the original scheme should go on; but towards the end of October it was announced that Her Majesty had been graciously pleased to assign Bushy House and grounds for the purposes of the laboratory, and that in order to meet the additional capital expenditure involved, the Government were prepared to ask Parliament to raise the grant of 12,000*l.* for building to 14,000*l.* This was accepted by the Council of the Royal Society, but it was pointed out that, to quote the words of the report:—

The executive committee "cannot, however, conceal from themselves that it will be very difficult for them to maintain and administer a national physical laboratory on the Bushy site for the amount annually allowed by the Treasury, and they fear that it may be necessary for them to press, in the near future, for an addition to that allowance."

Meanwhile, plan-making had to begin again. With the very cordial assistance of the Office of Works a new scheme was prepared and approved, and now the workmen are on the ground and the alterations have commenced.

Fortunately, the structural changes necessary will be remarkably small.

Bushy House is in many respects well suited, as it stands, for a physical laboratory; the basement, however, was dark and damp, and the whole sanitary arrangements needed reconstruction. The basement is to be improved by the construction of a dry area round the house, and the insertion of larger windows; the present flagged floor is to be removed, and to be replaced by concrete and cement. Modern drainage is to be introduced everywhere, and in place of the cess-pools now in use, connection is to be made with the public sewer; this necessitates a main drain some 300 yards long.

The house itself consists of a central block about 70 feet square, containing a basement and ground floor with two floors over. The ground floor rests on brick groining, forming the roof of the basement; it is thus possible to secure steady supports for apparatus at almost any point; the building is very substantial, and it will be easy to maintain a uniform temperature throughout the basement.

The front of the house faces east approximately; unfortunately, the two main rooms of the central block on the first floor look south and west respectively; in

[1] Report of the Executive Committee for 1900, and Programme of Work for 1901.

other respects they will make good laboratories, requiring only the provision of some steady supports, and, in common with the rest of the house, arrangements for heating and for the supply of gas, water and electricity for light and power.

But besides this main block, which is some 50 feet in height, there are five large wings, one at each corner and a fifth adjacent to the north front. This fifth wing, three stories in height, contains a number of small rooms, which will be of service for special pieces of work; the other four wings give the main laboratory accommodation. Two of these each contain two large rooms about 35 feet long by 25 broad—one of which has been subdivided—the other two are of about half the size, and contain one room each of the above dimensions. All these rooms are on the ground; they have excellent floors, and are in the main well lighted; in each wing there is considerable space between the ceiling and the roof; in two of the wings this space contains attic rooms. Thus omitting the room which has been subdivided, there are five large laboratories on the ground floor in the wings, and two in the central block. There are, in addition, a number of while some existing buildings will be utilised for a battery-room, a drawing office, and for other purposes. To the north of these buildings stand, at a distance of about 100 yards, the house. To minimise the risk of vibrations from the engine being felt to enter the physical laboratory, a Parson's Turbo-Generator will be used to provide light and power, and the latter will be transmitted electrically. The engineering laboratory will have a traversing crane fitted, and will contain the main workshop of the Institution.

The grounds of Bushy House, under the direct control of the Royal Society, are nearly twenty-five acres in extent; it will be possible, therefore, to put up, if required, isolated buildings for special experiments; the use, for example, of a large testing machine in the engineering laboratory might shake the physics laboratory, and would certainly disturb many of the experiments in the engineering laboratory itself. At present the funds available are insufficient to permit of the purchase of such a machine; if it is found that one is wanted, and money were forthcoming, the necessary buildings could be erected in another portion of the grounds.

[*Photo. by Lascelles London.*

FIG. 1.—National Physical Laboratory. Bushy House from the East.

other smaller rooms, and at the back various kitchen offices, which can easily be rendered most useful.

This general plan has some distinct advantages; it is not unlike Principal Lodge's ideal laboratory, a central block to serve as a museum, entrance-hall, offices, &c., with four wings assigned to definite branches of the work. Each wing is isolated from the others, and the chances of an observer being affected by his colleague in the next room are reduced. At the same time the difficulty of supervision is increased, while the fact that the levels are different in the wings and in the main building renders the transport of apparatus a matter of some trouble.

Our illustrations give a view of Bushy House from the east and a plan of the ground-floor.

This building will serve then for the more delicate physical measurements. For the engineering work a new laboratory is to be built; this will be 80 feet by 50 feet in area, with a weaving-shed roof lighted from the north and arranged so as to be easily capable of extension. Adjacent to it will be an engine and dynamo-room,

Together with their report the Committee presented a scheme of work for the current year.

The experimental work, which it is possible to do with the appliances at the Kew Observatory, is small; still it is hoped to increase the testing work which goes on there. Arrangements are being made for examining chemical measuring apparatus, flasks, burettes, and the like, and also, at the request of the Board of Agriculture, the bottles used in the Babcock milk test. An air thermometer, given by Sir A. Noble, has been erected, and will be in use as a standard of temperature up to about 400° C., while preparations are being made for the construction of mercury standards of resistance.

As to work for the future, which is to be taken up when Bushy House is occupied, the subject to which three, at least, of the Advisory Committees gave the first place was the connection between the magnetic quality and the physical, chemical and electrical properties of iron and its alloys, with a view specially to the determination of the conditions for low hysteresis and non-agency

properties. This problem, then, will, as soon as possible, be taken in hand.

Another important task is the testing of steam gauges, indicator springs and the like; for this purpose a mercury pressure gauge will be provided in the physics building to measure pressures up to twenty atmospheres —the height of the building will not allow more to be measured directly—together with an arrangement for multiplying in a known ratio the pressure measured directly.

Again, gauges of all kinds used in engineering practice will be tested, including the standard screws which the Small Screw Committee of the British Association hope to issue. Another problem which calls for early attention is that of wind pressure on surfaces.

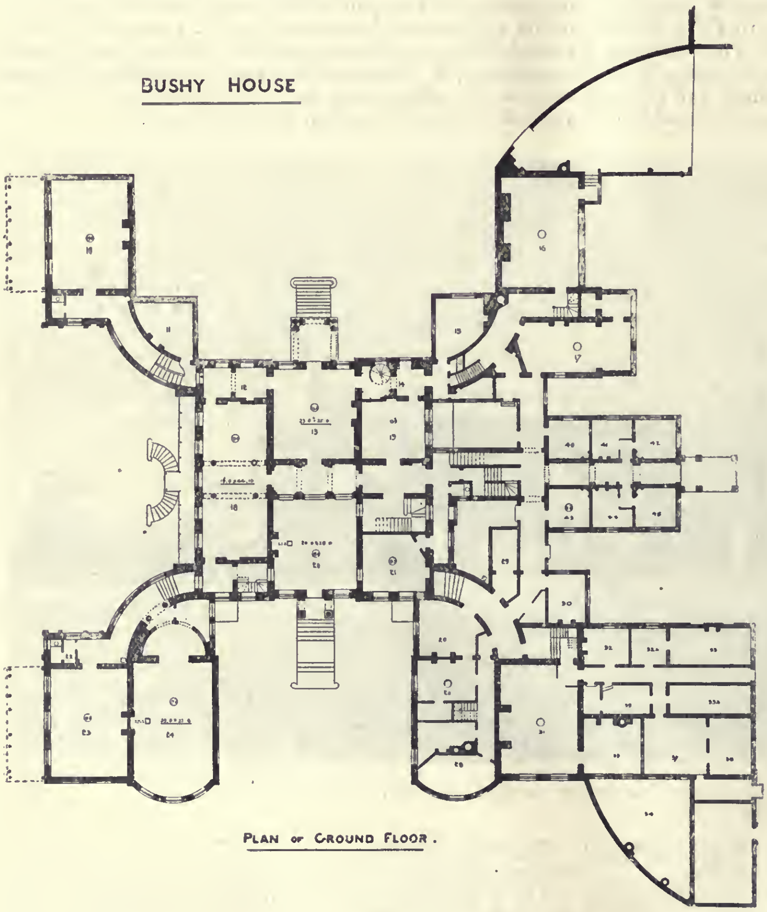

FIG. 2.

In electricity there is ample scope for work. The magnetic testing of iron for commercial use will be undertaken at once, and there are many forms of apparatus which do not come under the direct cognisance of the Board of Trade Electrical Department for which it is desirable to have some recognised test—*e.g.* condensers, special forms of cells, resistance boxes as distinct from standard coils and the like. A valuable list of measurements, by which the work of the Board of Trade Laboratory would be supplemented and assisted, has been submitted to the committee by Mr. Trotter.

Optical and thermometric testing is now carried out to a large extent at Kew Observatory, but both these branches of the work can be extended; the question of the measurement of very high and of very low temperatures is becoming more important each day. In the Optical Department photographic lenses are now tested by eye observations only. It is proposed to establish a photographic test, and to include microscope and other lenses.

It will be seen thus that there is a full programme of work before the staff of the laboratory; the Committee are anxious to keep in the closest touch with trade and industry, and the Director will welcome any suggestions to secure this end. The laboratory has been established to deal with physical problems bearing on manufacture and commerce; it can hope to succeed only through the cordial co-operation of the men who know what those problems are, and who can indicate the lines along which the necessary investigations should proceed; with their assistance it may soon do a national work.

THE PRESENT CONDITION OF THE INDIGO INDUSTRY.

FOR some time past letters on the subject of artificial *versus* natural indigo have been appearing in the *Times*. One by L. J. Harington, which appeared at the end of last month, is of considerable interest, since he writes as a planter of nineteen years' experience. He considers that the days of natural indigo are not numbered, and that the Government of India are not likely to take the advice of Dr. Brunck (NATURE, p. 111) and endeavour to grow food stuffs in place of cultivating indigo. He further remarks that "there is so little to choose between artificial and natural indigo that the whole thing is a matter of price, and the victory must go to the one who can afford to sell cheapest." He then goes on to say: "Indigo had always paid, at times well, at other times fairly so, and planters were content to grow and manufacture indigo exactly as their predecessors had done. Then in 1897 the Badische discovery came like a bolt from the blue." This is a rather remarkable admission. Here were men manufacturing indigo, and they had evidently not taken the trouble to ascertain what was being done in the scientific world and by other manufacturers. Were they not aware that so far back as 1880 indigo had been synthetically prepared, and that numerous patents had been taken out? Certainly the processes had not been commercially successful; but surely they should have taken warning, and endeavoured to improve their product and to manufacture it more cheaply.

Mr. Harington says that after the "bolt from the blue" in 1897 the price of indigo steadily fell until 1899, when, owing to the bad season, one of the finest crops ever seen in Behar was ruined and the price rose nearly 25 per cent. This naturally gave the producers of artificial indigo their chance, and they were able to offer their product at prices slightly lower than those ruling for the natural article. According to Mr. Harington, when synthetic indigo was first placed on the market the average cost of manufacturing Behar indigo was 170 rupees per maund, but that now, owing to more careful working and by sowing only on good lands, it

can be produced for 100 rupees, and he hopes that by engaging, not one chemist, but a dozen, the "cost of making indigo will soon be reduced to a level at which it will be quite impossible for synthetic to compete." Mr. Harington says, however, that the Behar planters cannot afford to spend more on experiments than they are now doing, and he appeals to the Indian Government to give a grant of at least 5000*l.* for five years. It is certainly refreshing when an indigo planter calls, not for one experienced chemist, but for a dozen. It is, unfortunately, more usual for manufacturers to sneer at chemists, saying that they only waste material in experimenting. Do they imagine that experiments which are carried out by chemists on the Continent and in America, and which enable these countries to undersell us, cost nothing?

If our manufacturers employed capable chemists and gave them a free hand, instead of employing what one may perhaps be allowed to term *glorified bottle washers*, there is very little doubt but that they would find experimenting does pay.

If it is true that, owing to bad seasons in India, the indigo producers cannot afford to pay for expert advice, then, owing to the enormous interests which are involved and the danger of delay, surely the Indian Government will not refuse its aid. It must, however, be remembered that Government cannot aid every industry.

It has already been stated in a previous article that Sir William Hudson had applied to the Indian Government for a loan to help the indigo planters to reintroduce the cultivation of the sugar-cane, as an auxiliary to the production of the dye-stuff. The Government of India thereupon appointed Mr. O'Conor, head of the Statistical Department, to report on the proposed scheme of rotating sugar with indigo crops.

Before 1840 sugar was cultivated and manufactured in Behar, but the methods employed were of the crudest, and transport was bad and expensive, therefore the production of sugar gradually died out, and many of the sugar planters turned to the manufacture of indigo. Since 1840 railways and good roads have been introduced. By careful selection and cultivation a better quality of cane-seed is now obtainable. Further, improved modern machinery and methods enable the sugar grower to obtain a much enhanced yield of a good class of sugar. The committee appointed to inquire into the possibility of the cultivation of sugar by indigo planters have nearly finished their work, and it is understood they are of the opinion that the cultivation should yield a handsome return to the planters in Behar, "*if its cultivation, manufacture and distribution are conducted on business principles.*" I might also add on *scientific* principles, and let them employ chemists who are able to do more than simply determine the strength of the sugar by means of a saccharometer. It is to be hoped that the indigo planters, if the cultivation of sugar is introduced, will not again settle down into lethargic coma with the idea that all is now well. They may be absolutely certain that any advantage which they obtain will only add to the energy with which the German men of science will attack the problem. F. MOLLWO PERKIN.

THE ROYAL INDIAN ENGINEERING COLLEGE.

ALL the members of the teaching staff at Coopers Hill must be gratified at the expression of public opinion in support of the cause of the seven gentlemen who have received notice of dismissal. Since our remarks upon the matter were written last week, leaders and letters have appeared in the *Times*, *Daily News* and other newspapers, expressing astonishment at the condition of things which permits distinguished men of science to be treated with indignity, and demanding that an inquiry shall be made not only into the present case of injustice, but also into the whole system which renders it possible for scientific service to be belittled by the action of an official unable to appreciate its value.

Testimonies to the importance and efficiency of the work done by the scientific staff at Coopers Hill have been given by men whose opinions carry weight with the public as well as in the world of science. As mentioned last week, Lord Kelvin has directed attention to the valuable work done at the College, and has given his great influence to the cause of the teaching staff. Prof. J. A. Ewing, F.R.S., professor of mechanism and applied mechanics in the University of Cambridge, has since come forward to add his testimony to that of Lord Kelvin and others. The following words of Prof. Ewing's are of particular value in enabling people to appreciate the gravity of the case.

"To suggest that the dismissal of men like Prof. McLeod and Prof. Hearson can make for efficiency is preposterous. I know nothing of the finances or of the administration of Coopers Hill, but I do know something of its teachers and of their teaching. I have examined Prof. Hearson's students at Coopers Hill, and have had the advantage of co-operating with him as examiner in the Mechanical Sciences Tripos at Cambridge. The pages of the Royal Society's *Philosophical Transactions* bear witness to his originality as a contributor to engineering science. Those who know, as I do, what fulness of knowledge and what infinite patience he brings to bear upon his teaching are not surprised that he teaches with success. One feels that to praise him is an impertinence, but when he and his colleagues are treated in this incredible fashion those who know their merits should speak out."

So far as personal qualifications are concerned, therefore, the dismissed members of the staff are perfectly competent to perform their duties; and the results obtained prove that the teaching has been done in a most efficient manner. But a much larger question is at issue. A writer, who signs himself "J. P.," in the *Times* substantiates this remark with a statement of personal experience.

"For upwards of a quarter of a century," he says, "Coopers Hill has supplied the Indian Public Works Department, and for more than half that time the Indian Forest Department, with a body of recruits whose efficiency has been the admiration of all those whose position and experience render them competent to judge the question, men with whom I for one (and I am sure that I express the opinion of all the older members of the Public Works Department) feel it an honour to be associated."

If it were worth while, evidence to this effect could be considerably multiplied, but no useful purpose would be served by doing so. Every one who has followed the expressions in the public Press since the letter from Colonel Ottley was published, is convinced of the abilities of the gentlemen who have been dismissed, and the efficiency of the College.

This efficiency has been attained in spite of circumstances tending to discourage the teaching staff. It is nothing short of a scandal that capable men like those giving instruction at Coopers Hill should be controlled as if they were orderly-room clerks or petty assistants in a private school, with a Mr. Squeers as their over-lord. The only reasonable way to carry on the work of an institution for higher education is to let the teaching staff be largely responsible for the arrangement of courses of studies as well as for the actual instruction, but this does not appear to be the method followed at Coopers Hill; for the present deplorable state of affairs could not have arisen if the views of the staff as to the reorganisation of studies had been obtained. "J. P." expresses this view in the following extract from his letter:—

"One of the reasons why it has been so successful is that former presidents have looked upon the college not as a field for the display of their own vanity, or for trying experiments

to prove their own powers of organisation, but as an institution of lofty traditions and high standards, the maintenance of which it has been their study to secure by constant watchfulness and such gradual changes as experience has shown to be necessary, rather than by hasty and sudden departure from the practice of the past. They have also recognised that the power of control vested in them is not one to be hastily and capriciously brought to bear upon every detail of the life of the college; that the members of the teaching staff are their colleagues and friends, men of honour, integrity and experience, whose advice and opinions on matters connected with their work should be sought for with eagerness and listened to with respect, even if they cannot ultimately accept them.

"When an institution has been worked under a particular system with conspicuous success for eight-and-twenty years, and in the twenty-ninth year we find, in place of order, chaos, in place of friendship and *esprit de corps* of the best kind, distrust and recrimination, when half the staff are dismissed with the notice that would be given to a coachman, and the other half are in the dark as to what their future duties are to be, when the students are on the verge of mutiny, and threats of dismissal are daily occurrences—it is not 'the system' which is to blame."

The president of the College apparently rules as an autocrat, and the members of the teaching staff have to do as he directs them, whatever their own opinions as to the scheme of work or value of subjects may be. The Board of Visitors has a conference with the president for an hour or so once a year, and his views or recommendations are naturally adopted. The board does not come into contact with the teaching staff, and the members are, therefore, unable to understand the conditions under which the work of the College is carried on. It is stated, indeed, that the Board of Visitors imagined the revised curriculum submitted to have been considered by the teaching staff, whereas the staff were not consulted.

We notice in the *Times* the statement that the Secretary of State for India has refused to grant the inquiry asked for, but it is to be hoped the matter will not be allowed to rest here. A strong deputation must be organised to present the memorial which we understand has been prepared, begging for an inquiry into the case, and directing attention to the position of the teaching staff in relation to the educational policy of the College. Unless there is a reformation, the case of the members of the staff left will be even worse than that of those who have been ordered to retire in such an inconsiderate way.

Among the signatures already appended to the memorial are those of—Lord Kelvin, Lord Lister, Lord Rayleigh, Sir William Huggins, Sir Frederick Abel, Sir Frederick Bramwell, Sir William Crookes, Sir Archibald Geikie, Sir Norman Lockyer, Sir Andrew Noble, Sir Henry Roscoe, Prof. Armstrong, Mr. W. H. M. Christie, Prof. Dewar, Prof. Ewing, Mr. R. T. Glazebrook, Mr. W. N. Shaw, Prof. J. J. Thomson, Prof. Marshall Ward, and of some seventy other Fellows of the Royal Society. Professors and teachers at all the educational centres in the country are sending in their names and testifying to the widespread indignation at the action of the India Office.

H. W. CHISHOLM.

MR. H. W. CHISHOLM, late Warden of the Standards, Board of Trade, died in his ninety-second year on January 16. He was formerly chief clerk of the office of the Comptroller General of the Exchequer, and on the abolition of that office in 1866 he was appointed to take charge of the old Department of Weights and Measures. In 1867 a new Standards Act was passed, by which all powers and duties of the Treasury and Exchequer were transferred to the Standards Department of the Board of Trade, and Mr. Chisholm was made the chief of the department with a salary of 1000*l.* per annum. In 1868, mainly on Mr. Chisholm's representations, a Royal Commission on Standards was appointed, on which he became an active member. The Commission included also the late Prof. W. H. Miller, Sir George Airy and General Sabine, eminent men of science, by whose efforts the Standards Department was raised to a prominent scientific position, furnished with proper standards of length, mass, capacity and cubic measurement, and with instruments essential for verifications for scientific purposes.

Mr. Chisholm held the appointment of Warden of the Standards until 1877, when he retired after fifty-three years of public service. With his retirement the title of Warden of the Standards was dropped, the duties then being undertaken by a superintendent of the Standards Department.

Mr. Chisholm issued an annual report during the ten years he held office, which was always full of information of great interest and public use, and in which metrological researches were dealt with in an exhaustive manner. For instance, amongst the subjects which his printed reports dealt with we find, besides the ordinary work of testing and comparing, standards of measure, &c., investigations as to the expansion of metals, density of water, effects of atmospheric pressure with reference to the measurement of gas, calculation of probable errors of observation in micrometric work, &c.

Mr. Chisholm took a prominent part in the early work of the Bureau international des Poids et Mesures at Paris, which was established under a Metric Convention; and he represented Great Britain at a diplomatic conference at Paris in 1875. In 1877 he published a book relating to the history, &c., of the standards, entitled "Weighing and Measuring" (Macmillan).

With Mr. Chisholm an important link has passed away between the old and the new civil servants, and all who had the pleasure of knowing him well will remember for many years his varied abilities, cheerful disposition, and his desire to help others.

NOTES.

IN consequence of the death of the Queen, all the lectures at the Royal Institution have been abandoned until further notice.

WE have received information from Cairo that the time ball at Port Said is dropped daily at 12 noon (30° meridian time) by direct automatic signal from Abbassia Observatory. Omdurman receives the same signal, and from about the middle of February the time ball at Alexandria will be similarly controlled. Arrangements have been made by which a daily weather telegram at 8 a.m. is exchanged between Alexandria and Malta, Brindisi, Trieste, Athens and Beirut. The information so received is posted outside the port offices at Alexandria and Pord Said daily for the use of shipping.

PROF. R. BLANCHARD has resigned his office of general secretary of the Zoological Society of France, after twenty-three years of service. The Society has decided to present him with a medal in commemoration of his work.

WE regret to see in the *Times* the announcement of the deaths of Dr. Danckelmann and M. Gramme. Dr. Danckelmann was director of the Prussian Royal Academy of Forestry at Eberswalde. He rendered great services to the science and art of forestry in Prussia, and was one of the first to advocate effectively the training of foresters in special colleges. He took a leading part in the teaching at Eberswalde and was the author of many interesting works on forestry. M. Gramme will be remembered by his inventions in connection with dynamos and electric batteries. For his dynamo he received 20,000 francs from the French Government and the Volta prize of 20,000 francs from the Academy of Sciences.

THE annual general meeting of the Geologists' Association will be held at University College on Friday, February 1. The president, Mr. W. Whitaker, F.R.S., will deliver an address entitled "Twelve Years of London Geology."

THE thirty-first course of lectures and demonstrations for sanitary officers will commence at the Sanitary Institute on February 1. There will be four lectures on elementary physics and chemistry in relation to water, soil, air, ventilation and meteorology; twenty-one lectures on public health statutes, the practical duties of a sanitary inspector, municipal hygiene, and building construction; and seven lectures on meat and food inspection.

CAPTAIN J. C. BERNIER, of Quebec, is in England, and has described to a Reuter's representative and the Royal Colonial Institute his plans for an Arctic expedition, which have received the approval of the Quebec Geograpical Society. His first plan is to enter Bering Strait during July, and, following the Siberian coast, the ice would be entered between 170 and 165 degrees, as far east as its state would permit, pushing north in August and September, and dropping buoys at intervals to test the ice drift. Monthly, as the wind suited, small balloons would be despatched with records, each balloon having a copy of the previous records. Photography would be largely employed, kites being used for long-distance photographs. With suitable appliances, it was known that a long distance could be run on the packed ice during the proper season. In the second spring and summer it is suggested that two routes be taken—one in a north-east, the other in a south-west direction—with stations at intervals, keeping communication with the ship by wireless telegraphy and gun signals. The routes would be marked at mile intervals by hollow staves, the hollows being filled with condensed provisions and records, and each staff would be numbered. When in the neighbourhood of the Pole, the north-eastern route would be extended to more stations, always in communication with the ship. These plans are to be laid before the Canadian Government.

THE annual report of the Council of the Institution of Mechanical Engineers was read at the annual meeting on Friday last. We learn from it that the award of the Willans premium has been for the first time in the gift of the Council, and, from the papers read before the Institution since the foundation of the fund in January 1895, they have selected that read in April 1895 by Captain H. Raill Sankey, on "Governing of Steam-Engines by Throttling and by Variable Expansion," as the most suitable for the award. Sir William Roberts-Austen is still at work upon the sixth report to the alloys research committee, dealing mainly with the effect of annealing and tempering on the properties of steel. Prof. F. W. Burstall expects to complete his second report to the gas-engine research committee in the course of a few weeks. Progress has been made in the experiments on the value of the steam-jacket, by Prof. T. Hudson Beare. Prof. D. S. Capper has made a first series of tests on the compound steam-jacketed engine at King's College with different steam-pressures and speeds, working single-cylinder, non-condensing. The results have been worked out, and are expected to be ready shortly. The Council have consented to take charge of the mechanical section of the Glasgow International Engineering Congress, the meetings of which will be held during the first week of September. They have also decided that these arrangements should not interfere with the ordinary summer meeting of the Institution, which will be held during the last week in July at Barrow-in-Furness. Mr. W. H. Maw has been elected to succeed Sir W. H. White as president of the Institution.

THE experiments made with a view to using liquid air as one of the constituents of an explosive are described by Mr. A. Larsen in a paper (No. 786) received from the Institution of Mining Engineers. The cartridges used for blasting trials in the Simplon tunnel consisted of a wrapper filled with a carbonaceous material, such, for instance, as a mixture of equal parts of paraffin and of charcoal, and dipped bodily in liquid air until completely soaked. The cartridges were kept in liquid air at the working face of the rock until required for use, when they were put quickly in the shot-holes and detonated with a small guncotton primer and detonator. The life of such a cartridge is, unfortunately, very short after the cartridge has been removed from the liquid air. A cartridge eight inches in length and three inches in diameter has to be fired within fifteen minutes after being taken out of the liquid to avoid a miss-fire. On this account the Simplon trials were discontinued; nevertheless, Mr. Larsen says that much attention is still being devoted to the matter in Germany, where investigations are being carried on in three different centres, one of them being the largest explosives works on the Continent, namely, the carbonite factory at Schlebusch.

A REPORT of the Government of India shows that during the year 1899 the number of deaths among human beings attributed to wild animals was 2966. Tigers caused the death of 899, wolves of 338, and leopards of 327 human beings, while bears, elephants, hyenas, jackals and crocodiles were accountable for a large proportion of the remainder. The loss of human life from snakes reached the high total of 24,621, a greater mortality than in any of the four preceding years. Nearly half the deaths occurred in Bengal, while the North-Western Provinces and Oudh came next with nearly one-fourth of the total. In Bengal the relatively high mortality is attributed to floods, which drove the snakes to the high lands on which village homesteads are built. As will be observed, snakes are more destructive of human life than are the wild animals, but the reverse is true of the destruction of cattle. In 1899 no fewer than 89,238 cattle were destroyed by wild animals, and 9449 by snakes.

THE U.S. Weather Bureau has published a very useful and comprehensive treatise on West Indian hurricanes, by Prof. E. B. Garriott (*Bulletin*, No. 232). The chief of the Weather Bureau points out that the paper in question reviews the writings of the more prominent meteorologists of the past century, so far as they refer to the tropical storms of the North Atlantic, and that it graphically illustrates and describes the more important hurricanes that have occurred during the last twenty-five years. A table is given (partly taken from that by Señor A. Poey) of the chronological occurrence of West Indian hurricanes since 1493. This list shows that while storms occurred in every month, the great majority took place between July and October. During the principal hurricane months the storms generally recurved east of the Gulf of Mexico, the mean track being farther west in September, when it approached very near the East Florida coast. But the tracks from 1878 to 1900, which are laid down on charts, show that during the principal hurricane months recurvature may occur from far to the eastward of the Bahamas to the west coast of the Gulf of Mexico.

WE have received from the meteorological reporter for Western India a copy of his "Brief Sketch of the Meteorology of the Bombay Presidency for 1899–1900." The meteorology of the year is of more than usual interest, owing to the almost unprecedented failure of the south-west monsoon rains over a large region, and the consequent partial or total failure of crops and water supply. From a statement showing the most severe droughts and famines of the last 150 years, and the areas affected, it appears that the drought of 1899 and famine of 1899–1900 extended over a very much larger area than that of

previous years. The failure of the rainfall was chiefly due to the weakness of the Arabian Sea monsoon current, which generally brings heavy rainfall in July and August. Another feature of the year was the abnormal high barometric pressure which obtained during the monsoon months. The observations of many years show that such conditions are attended by a general decrease in the rainfall; in the years 1876, 1896 and 1899, the most recent years of drought, the average pressures during the monsoon months were ·015, ·012 and ·054 inch, respectively, above the normal. It is noteworthy that in South Africa 1899 appears to have been a year of excessive rainfall.

THE *Electro-Chemist and Metallurgist* has made its appearance, and we trust it has come to stay; for it should be the means of directing attention to a very promising branch of applied electricity, and of advancing a knowledge of electrochemistry. Germany has two periodicals devoted exclusively to electro-chemistry, and is in advance of us, not only in this respect, but also in the provision made for the study and use of electro-chemical processes. The first article in the new periodical, on "Recent Progress in Electro-chemistry," shows that England's share in the advances of recent years is not in proportion to her position in science and industry. It is stated that the total horse-power expended in electro-chemical industries is about 400,000, "equivalent to a total yearly production valued at over 30,000,000*l.*, of which the United States contributes between 60 and 70 per cent., Germany and France about 10 per cent. each, Switzerland about 2 per cent., and England not more than 1½ per cent." Among the subjects of other articles in the journal are little-known carbides, borides and silicides; electro-chemistry at the Paris Exhibition; deposition of metals from mixed electrolytes; and the present and future of accumulators. In addition, there are several pages of abstracts from foreign contemporary journals, and from recent patent specifications. The journal will be published monthly, and should have a wide sphere of influence in the electrochemical and metallurgical professions in England.

TO the December issue of the *American Naturalist*, Prof. H. F. Osborn contributes the third instalment of his investigations into the origin of the Mammalia, taking as his text the evolution of the occipital condyles of the skull. It has been very generally supposed that the paired mammalian condyles are inherited directly from those of the Amphibia. This, however, the author considers to be a misconception; his objection being largely based on the circumstance that in the Amphibia the condyles are derived exclusively from the exoccipitals, without any trace of a basioccipital element. On the other hand, in many mammals, especially Echidna, the basioccipital forms the basal portion of the condyles, or, at all events, the intercondylar interval; and it is shown by figures how such condyles are traceable to the tripartite condyle of reptiles by the gradual abortion of the median basal element. In fact, one anomodont reptile (*Cynognathus*) has actually attained the dicondylar type by means of this elimination.

IN the same journal, Prof. C. S. Minot, preparatory to the publication of a text-book on the subject, calls attention to his own method of teaching mammalian embryology. He recommends, first, the study of pig embryos of from 9 to 12 mm. in length, and, secondly, larger examples of the same, after which the embryo chicken should be taken in hand to illustrate the germ-layers. Then should come the study of the fœtal envelopes, including the human placenta, and finally an investigation of the genital elements, segmentation, &c. Before calling attention to the importance of the "cervical bend" as distinctive of mammalian embryos, Prof. Minot takes occasion to refer to the superiority of the German system of "black line" wood-engraving for the purpose of illustrating embryological studies, the cheapness of German work being likewise an important factor.

DR. J. BEARD, of Edinburgh, has recently contributed to the current volume (xviii.) of the *Anatomischer Anzeiger* two suggestive papers bearing on the fate and function of that physiological puzzle, the thymus gland. In the former of these (Nos. 15 and 16) he identifies a certain structure in the spiracle of the ray (Raia) as the representative of the thymus. In the latter (Nos. 22 and 23) he arrives at the conclusion that the thymus is the source of all the "leucocytes" of all true vertebrated animals, and hence that it is the origin of all the lymphoid structures of the body. The latter statement, he observes, throws light upon the fact that the thymus is an example of an organ which, after being functional in early life, gradually atrophies. "This is only certainly known to happen in mammals, and from it the inference is drawn that in later life the organ ceases to exist. It no more ceases to exist than would the Anglo-Saxon race disappear were the British Isles to sink beneath the waves."

AN interesting description of the ravages of white ants, or termites, in Rhodesia is furnished by the Rev. A. Lebœuf to the *Zambesi Mission Record* for January. The special interest of the contribution centres in the account of the damage done to property by white ants in Rhodesia, which seems to be even greater than in India. It is no uncommon thing, says the writer, for the colonist, on returning from his day's labour, to find the coat he left hanging on a nail of his cottage wall and the books on the table absolutely destroyed by these tiny marauders. Nor is this all. "On awaking next morning," writes Mr. Lebœuf, "you are astonished to see in the dim light a cone-shaped object rising from the brick floor a short distance from your bed, with two holes on the top like the crater of a miniature volcano. Upon closer examination you discover that the holes have just the size and shape of the inside of your boots, which you incautiously left on the brick floor the night before. They have given form and proportion to an ant heap, and nothing is left of them except the nails, eyelets and, maybe, part of the heels." And as the same dismal story—with variations—has to be told about every other article of apparel and all perishable objects, it must be admitted that there are drawbacks to the lot of a settler in Rhodesia.

THE *Agricultural Students' Gazette* for December contains an appreciative article on the late Sir John Bennet Lawes, who always took a kindly interest in the success of the college at Cirencester.

THE West of Scotland Agricultural College has sent out an interesting report on a series of experiments on the growth of oats in the season of 1899. A considerable number of the leading varieties were grown under equal conditions in various districts of Scotland; their yield, as regards grain, straw, meal and husk, being subsequently determined. While the results of a single season—and that an altogether abnormal one—cannot be accepted as final, enough is shown to justify further attention being bestowed on the matter. Greater care should, however, be given in future to safe-guarding the crops against the depredations of birds and ground game, for where such pests are admitted to have interfered with growth, a justifiable lack of complete confidence in the results is engendered. On the whole the older varieties have come satisfactorily through the trial, most of the newer sorts being apparently unable to contend successfully with unfavourable conditions of growth. They have, moreover, in some cases an undesirably thick husk, and a correspondingly small kernel. It is to be hoped that Profs. Wright and McAlpine have continued this work during the past season.

THE current number of the *Journal* of the Royal Agricultural Society of England opens with an interesting account, from the pen of Dr. Voelcker, of the results obtained by means of pot-culture at the experimental station at Woburn. He first points out the advantages and the limitations of this form of research, and, like Wagner, of Darmstadt—the originator of this method of cultural experiment—advises that results obtained in pots shall subsequently be tested in the field before they can be confidently recommended to the attention of practical agriculturists. A considerable amount of time has been taken up in testing the effects, on farm crop-plants, of "rare forms of earth," as stipulated by Mr. Hills in his bequest. For the most part the results are not encouraging, though some benefit appears to have resulted from steeping the seeds of cereals in one per cent. solutions of sodium iodide and sodium bromide. Where equal numbers of large and small seeds of wheat and barley were sown in separate pots the yield was, rather unexpectedly, but little affected by the difference in character of the seed. The journal, further, contains some interesting matter on the manufacture and ripening of cheese, by Prof. Reynolds Green, and the valuable report of the Tuberculin Committee.

THE phenomenon of anaërobic life, originally discovered and defined by Pasteur as the existence of living forms in the absence of oxygen, has recently had fresh light thrown upon it by the important researches of Dr. Klett, of Würtemberg. Investigating the problems surrounding the production of spore-less anthrax outside the living body, Dr. Klett has found that if anaërobic conditions for the bacillus are provided by the substitution of nitrogen for air, the growth of the organism is not impaired, and spores develop as freely as under ordinary conditions. If, however, the air be replaced by hydrogen, no spores develop providing the nutritive medium is of a character which permits of the gas being in intimate contact with the culture. It is not, therefore, as supposed by so many investigators, the absence of oxygen which is responsible for the non-production of spores in so-called anaërobic cultivations of anthrax, and this view is also supported by Dr. Weil's experiments on this subject. The mystery of the phenomenon remains still to be solved; meanwhile Dr. Klett has provided a new method for the production of sporeless or asporogène anthrax, and in future it will be advisable to supplement the term anaërobic as applied to a micro-organism by referring to the conditions under which the latter was deprived of air.

THE Zoological-Botanical Society of Vienna will hold its Jubilee meeting on Saturday, March 30. Representatives of the various learned societies with which the Society is in correspondence are invited to the meeting. Information from those intending to be present is requested by the secretaries not later than the middle of February.

TWO communications have reached us from the U.S. Department of Agriculture (Division of Vegetable Physiology and Pathology). The first (*Bulletin* No. 25), by H. Von Schrenk, deals exhaustively with the diseases caused by fungi to which conifers are liable in New England, the symptoms of the disease, the nature of the injury inflicted, and the remedies. The parasitic fungi to which attention is specially directed are *Polyporus Schweinitzii*, *P. pinicola*, *P. sulfureus*, *P. subacidus*, and *Trametes Pini*. The second (*Bulletin* No. 23) describes a disease, known as the spot disease, to which violets grown in America are liable, so virulent that the cultivation of the flower has been abandoned in many parts of the country. It is due to a parasitic fungus, probably of American origin, which the author, Mr. P. H. Dorsett, describes as a new species under the name *Alternaria Violae*. Both papers are very well illustrated.

PROF. STRASBURGER has recently published, in the *Biologischen Centralblatt*, an account of his observations on certain diœcious plants, especially *Melandrium* (*Lychnis dioica*). It is well known that the flowers of this plant are normally unisexual, and that there are also certain correlated differences, *e.g.* the elongation of the internode between the calyx and the corolla, which are likewise characteristic of the staminate flowers. But whereas the stamens are, as a rule, reduced to minute rudiments in the female flowers, they are stimulated to develop, in a normal manner, if the plant happens to become infected with the smut fungus, *Ustilago violacea*. The stamens then grow and advance so far as to form the pollen mother cells in a manner indistinguishable from the process as it occurs in the ordinary staminate flowers; but the fungus, perhaps owing to the abundant supply of available nutrition, then becomes virulent, it kills and consumes the cells, and the anthers are finally filled with the purple spores of the parasite. Nor is this all, for the ovary becomes arrested in its development, the ovules hardly advancing beyond the embryo-sac formation. Moreover, the lengthening of the calyx-corolla internode referred to above also occurs, and these facts have given rise to the mistaken impression that the fungus merely castrated the stamens of a male flower, causing the female organs to develop. This is not the case, for when the male flowers are attacked there is no development of the pistil to be seen. Prof. Strasburger utilises these results as the basis for a treatise on the possibilities of artificially interfering with, or determining, the sex of unisexual organism, and the whole paper is well worth careful reading for the wealth of illustration and critical exposition which it contains. The conclusion is reached that it is not possible, at least in the higher plants and animals, to influence the sex of an individual either by nutrition or by modifying the normal physical environment. The organism in this respect develops on predetermined lines, and only an extraordinary stimulus can surprise the latent potentiality into active development.

A CATALOGUE of the recent marine sponges of Canada and Alaska is contributed by Mr. L. M. Lambe to the *Ottawa Naturalist* (vol. xiv. No. 9).

PROF. E. RICHTER has issued the fifth report on the periodic variations of glaciers (*Archives* des Sc. phys. et nat. Genève, tome x. 1900). References are made to glaciers in Europe, the Polar regions, North America and Asia.

MR. R. E. C. STEARNS publishes some revisions of the nomenclature of Tertiary land shells of the John Day Region in Western North America (*Proc.* Washington Acad. Sc. vol. ii. December 1900). Thus the species named *Helix* (*Aglaia*) *fidelis*, Gray (Stearns) now becomes *Epiphragmophora fidelis antecedens*, Stearns. Truly multiplication becomes vexation in the case of zoological names.

WE have received the annual report of the Geological Commission of the Cape of Good Hope for 1898 (Cape Town, 1900). It is a record of arduous but highly interesting work, hampered to some extent by the want of good maps, but of acknowledged advantage to the inhabitants of Cape Colony. The field-work has been carried out by Messrs. A. W. Rogers and E. H. L. Schwarz under the superintendence of Prof. Corstorphine, and they furnish detailed reports on the districts examined, including the country around Worcester.

THE Geological Survey of India has lately issued several important scientific works. In the Memoirs (vol. xxviii., Part 2) there is an essay on "The Charnockite series, a group of Archæan hypersthenic rocks in Peninsular India," by Mr. Thomas H. Holland. The history of the naming of this series is interesting. A hypersthene-granite, regarded as a new type, and composed of hypersthene, microcline, quartz and accessory iron-ores, was

discovered in 1892; and it was afterwards found that the tombstone of Job Charnock, the founder of Calcutta, was made of the same rock, so the name Charnockite "was suggested for it in honour of the man who was the unconscious means of bringing the first specimen of this interesting rock to the city which ultimately became the capital of India." The members of the Charnockite series are now fully described and illustrated. They are regarded as igneous in origin, and as intrusive in the older schists and gneisses.

IN the "Palæontologia Indica" we have (in series xv., relating to Himalayan fossils, vol. iii. part 2) a monograph on the Trias Brachiopoda and Lamellibranchiata, by Dr. Alexander Bittner, a work translated by Dr. and Mrs. A. H. Foord. About sixty species are described. The genera are all well known and generally distributed in the Alpine Trias. Identical species, however, are only sparingly represented in India. Another monograph (belonging to series ix., Jurassic Fauna of Cutch, vol. ii. part 2) is on corals, by Dr. J. W. Gregory. A magnificent collection of corals from the Peninsula of Cutch was made by Wynne and Fedden and Stoliczka between 1867 and 1872. It was sent to England in 1890 in the hopes that the late Dr. Duncan would undertake the task of description. Owing to failing health he requested Dr. Gregory to carry out the work, and this the latter has now done with conspicuous ability, but not without much anxious consideration. The author was reluctant at first to treat as mere individual variations differences which in the case of the corresponding European corals are regarded as of specific value; but he was driven, and happily so, to this course, as the alternative was the creation of some 3,000 new species or varieties. The bulk of the collection comes from the Putchum Beds (Bathonian) to the north-west of Jumara, and they represent a coral bank rather than a reef. Some corals were obtained from the Chari Beds (Callovian and Oxfordian), and some indicate higher geological horizons. In all seventy-one species are desciibed, and illustrated in a series of excellent plates.

THE question of Hindu castes is treated by Mr. Tribhovandas Mangaldas Nathubhai in the *Journal* of the Anthropological Society of Bombay (vol. v. p. 74). He points out that "the present castes did not strictly adhere to their original distinguishing characteristics," and that the spirit of the original laws "not being rightly understood and followed, they yielded not the advantages intended, and produced evils never contemplated." The author makes some sensible remarks on the remarriage of widows; and with regard to the caste system he advocates, not abolition of caste or the raising of the status of the lower castes, but a reversion to the teaching of the Shastras. In the same number of the journal are some notes on the folklore of the lizard and ominous birds in India.

AN article upon Huxley's life and memoirs appears in the January number of the *Quarterly Review*.

THE meteorological observations made at the Adelaide Observatory and other places in South Australia and the Northern Territory during the year 1897, under the direction of Sir Charles Todd, K.C.M.G., F.R.S., are tabulated and discussed in a volume just published by the Government of South Australia.

A NEW volume of "The Fauna of British India, including Ceylon and Burma," edited by Dr. W. T. Blanford, F.R.S., has been published under the authority of the Secretary of State for India. The author of the volume is Mr. R. I. Pocock, who mentions in the preface that it "contains descriptions of all the species of Arachnida of the orders Scorpiones (scorpions), Uropygi (whip-scorpions), Amblypygi, Solifugæ, and of most of the larger and otherwise conspicuous species of Araneæ (true spiders) known to occur in British India, Burma and Ceylon, together with diagnoses of the genera, families and sub-orders into which they fall."

Popular Astronomy for December 1900 contains the address delivered by Mr. J. A. Brashear at the ceremony of laying the foundation stone of the New Allegheny Observatory at Riverside Park, Allegheny, Pa The history of the institution is reviewed since its incorporation in 1860. Prof. F. L. Wadsworth is the present director of the Observatory. The existing fine equipment is to be considerably augmented, and a special feature is that one department is to be open day and night to the students in the high schools and higher grades of the common schools, and also to citizens—a proposal first suggested by the late Prof. J. E. Keeler, a former director.

MESSRS. ILIFFE, SONS AND STURMEY, LTD., have sent us the fourth edition of Mr. John A. Hodges' "Practical Enlarging." This edition, we find, has not only been thoroughly revised and brought up-to-date, but much additional matter has been included. The worker is provided with a sound and elementary practical handbook, and it is interesting and important to note what the author states in the preface, that "no formula is given, nor any method of working described, which I have not personally thoroughly tested and proved to be trustworthy." With the introduction and general use of hand cameras and lenses giving flat fields, the process of "enlarging" the originals is now so widely adopted that such a serviceable handbook as this will be found most useful.

"WILLING'S PRESS GUIDE" is a handy index to the press of the world. The newspapers and other periodicals included in the lists are classified alphabetically according to title, and are also arranged in other groups according to place of publication and subject. We notice a few curious entries in the various classes of scientific publications of the United Kingdom. Under Astronomy the reports of two observatories are included, and "Astronomical Leaflets" which are not known to us. Under Science also several unimportant publications are named, while others are omitted. For instance, the *Journal* of the City of London College Science Society is given, but the *Philosophical Magazine* does not appear in the list, though it does appear under Philosophy. Reports of local scientific societies are also mentioned under Science and other heads, but the "Year-Book of Scientific Societies" shows that the number of omissions far exceeds that of societies included. If space cannot be found for the reports of all important local societies concerned with natural history and other sciences, it would be better to omit such societies entirely. At present the lists do not give a correct view of the publications of societies of this kind.

SOME interesting measurements of the electromotive force of concentration batteries containing non-aqueous solutions are communicated by L. Kahlenberg in the *Journal of Physical Chemistry* (vol. iv. p. 709). Whereas the E.M.F. of batteries containing aqueous solutions has been shown in very many cases to agree quite well with the potential difference calculated on the basis of Nernst's osmotic theory, the author's experiments indicate that the difference between the observed and calculated electromotive force is very considerable in the case of solutions in non-aqueous solvents. In view of the discrepancies, it is suggested that Nernst's formula should be subjected to a rigid test for the case of non-aqueous solutions.

A COURSE of lectures on electro-chemistry to a large audience is only with great difficulty capable of being illustrated by quantitative experiments. The usual methods of measuring current, resistance, voltage, &c., cannot readily be adapted in a completely satisfactory manner to the exigencies of the lecture-

table. A measuring instrument to remedy the defects associated with the use of the ordinary apparatus is described by Messrs. Miller and Kenrick in the *Journal of Physical Chemistry* (vol. iv. p. 599). Provided with a dial two feet in diameter, and "dead-beat" in its action, the instrument is so arranged that ohms, mhos, volts and amperes can be read off directly, and it can be changed from any one use to any other without delay. A series of fifteen quantitative experiments, chosen so as to illustrate the various principles of electro-chemistry, and which can be shown to a large class by means of the instrument, are described by the authors.

THE additions to the Zoological Society's Gardens during the past week include a Stanley Crane (*Anthropoides paradisea*) from South Africa, presented by Mr. J. E. Matcham; a White Pelican (*Pelecanus onocrotalus*), a Lesser Black-backed Gull (*Larus fuscus*), European; a Yellow Hangnest (*Cassicus persicus*), a Common Boa (*Boa constrictor*) from South America, two Japanese Greenfinches (*Ligurinus sinicus*) from Japan, a Yellow-winged Sugar-bird (*Coereba cyanea*) from South America, a Three-striped Boa (*Lichanura trivigata*), a Chained Snake (*Coluber catenifer*), a —— Snake (*Zamenis taeniatus*), a —— Snake (*Rhinochelus lecontii*) from North America, deposited; an Axis Deer (*Cervus axis*), born in the Gardens.

OUR ASTRONOMICAL COLUMN.

NEW VARIABLE STARS.—Two more variables are announced in the *Astronomical Journal*, vol. xxi. No. 487, as having been detected by Mr. R. T. A. Innes, at the Cape Observatory.

24.1900. *Arae.* This star is C.P.D. – 49° 10361, and has the position

$$\left.\begin{array}{ll} \text{RA.} = & 17^{\text{h}}\ 49^{\text{m}}\ 32^{\text{s}} \\ \text{Decl.} = & -49^\circ\ 24'{\cdot}9 \end{array}\right\} (1875).$$

The range in magnitude is from 8·9 to 9·75, and the period very short—about 7h 28m. 36s.

25.1900. *Octantis.* This star is No. 9192 in Gillis's Polar Zones, and has the position

$$\begin{array}{ll} \text{R.A.} = & 13^{\text{h}}\ 9^{\text{m}}\ 32^{\text{s}} \\ \text{Decl.} = & -83^\circ\ 34'{\cdot}1 \end{array}$$

The variation in magnitude is from 7·7 to 10·3.

THE ALMUCANTAR.—The Case Observatory, Cleveland, Ohio, has recently been equipped with one of the new type of instruments invented by Dr. S. C. Chandler in 1879, and in the *Astronomical Journal*, vol. xxi. No. 488, Mr. C. S. Howe gives a description of its construction and working, illustrated by photographs of the instrument in position. It is adaptable for all determinations usually made with the transit circle, as time, latitude, right ascensions and declinations, &c., but has several advantages. As the name implies, the instrument is inclined at a fixed elevation, generally equal to the latitude of the station, and being free to move in a horizontal plane, the times of passage over the parallel of altitude are observed in exactly similar manner to meridian transits; in general both transits may be observed, east and west. The advantages claimed are (1) elimination of flexure; (2) elimination of refraction errors depending on zenith distance, leaving only those produced by variations of pressure and temperature; (3) greater precision of fundamental plane of instrument; (4) greater extent of sky available.

The Case almucantar has an object-glass of 6 inches aperture and 60 inches focus, by Brashear, and instead of the telescope being inclined, the light is reflected from a mirror inclined at the proper angle, outside the object-glass.

The whole of this optical apparatus rests on a massive hollow iron ring 57 inches in diameter, which floats in mercury, means being provided for preventing lateral movement. The float, telescope tube and frame weigh about 1800 pounds, and additional weights are provided for adjusting the position of the centre of gravity. Preliminary experiments show that, although the instrument weighs about 2300 pounds, the oscillations after it has been moved die out in slightly over one minute, so that stars can be observed at intervals of three minutes. Another of these instruments, of about the same size as the above, has been erected at the Durham Observatory, and is described by Prof. R. A. Sampson in *Monthly Notices*, vol. lx. pp. 572–579.

THE ETHNOLOGY OF ANCIENT HISTORY DEDUCED FROM RECORDS, MONUMENTS AND COINS.

SERIOUS students of ancient history are fully aware that the narratives which have been preserved by professional historians are usually so eclectic and so meagre in many important details that they require to be largely supplemented by other data before the full significance of the events can be appreciated. The spade of the archæologist has provided innumerable documents of the greatest historical importance which serve to supplement the imperfection of the written record, and the observations and measurements of the physical anthropologist have to be called into evidence as well as the comparative studies of the ethnologist. The historian who ignores archæology, physical anthropology and ethnology deprives himself of the most voluminous of historical documents which lead, when carefully studied, to accurate conclusions. Thus alone can written records be established.

As in the distribution of animals, so in that of man, it is impossible to draw a line of demarcation between Europe and Asia. The pure Northern European type is as distinct as possible from the true Mongol, but there is such a chain of links between these two primary human races that they pass insensibly into one another.

It is now generally admitted that the fair dolichocephalic European race (*Homo Europaeus*, the Northern or Nordic race of some authors, the Aryan of others), stretched in Neolithic times far away into Asia, where they mixed to a variable extent with the Mongols, more so to the eastward, less so to the westward. To portions of this hybrid population have been applied such terms as Allophylian, Turanian, Finno-Turki, Ural-Altaic, Ugro-Altaic, Turko-Tatar, Mongolo-Turkic, Tatar, Turki. Part of this spectrum of mixed peoples was spoken of by ancient historians under the collective name of Scythians, those in Europe being "Aryans," those in the extreme east being largely Mongolised.

A short, dark, brachycephalic race (*Homo Alpinus*, Alpine or Slavo-Celtic race) which wandered into Central France in Neolithic times still persists in a central zone across Europe and into Asia, and there can be little doubt that this element also entered into the population of Western Asia in very early times. But at whatever period they arrived, their descendants can be found amongst the Tadjiks, who are brown brachycephals and quite different from the brachycephals of the yellow race whose point of origin appears to have been towards Tibet, whereas Lapouge and Ujfalvy believe the former to have followed the dolichocephals either from Asia Minor or from Europe.

A third race, of medium stature and dark complexion, is the dolichocephalic Mediterranean group (*Homo Mediterranensis*). This was located in Neolithic times in Western and Southern Europe, Northern Africa, South-Western and Southern Asia. The Dravidian peoples of India do not now concern us, and attention need be drawn only to the Semitic branch of the Mediterranean race, with its various offshoots. It is possible that the rise of Babylonian culture was due, as Keane points out, to the influence of Semites on the indigenous Akkado-Sumerians, who were almost certainly of Finno-Turki origin.

The typical Mongols (*Homo Mongolicus*) are a short, brachycephalic people with a yellowish skin, high cheekbones, very characteristic eyes, lank, black hair on the head, and sparse hair on the face. This race is as purely Asiatic as the negro is African.

The easterly drifting of tall, fair, long-headed peoples speaking dialects of the Aryan group of languages took place, perhaps, about 2000 B.C. The migrants to India had scarcely attained the agricultural phase of culture, and it was not until the conquests of Alexander in 327 B.C. that a true civilisation flourished in the Panjab. The Persian branch advanced much more rapidly, owing to their proximity to the ancient civilisations of Mesopotamia.

Few portions of the world have had so complex a history as the region between the Caspian Sea, the Persian Gulf and the

Himalayas. Streams of migrations have passed through this district, to be caught up into ethnological eddies of which written history is incompetent, by itself, to unravel their intricate movements and blendings.

There is insufficient evidence concerning the physical type or types of the ancient inhabitants of Persia, but one predominant primitive Persian type resembled that of the ancient Hindus, that is, both were long-headed (dolichocephalic), narrow-faced (leptoprosop), with long, thin noses (leptorhine). They also had skulls of but slight height, which were flattened above. In all these respects these Persians of the time of the Achæmenian dynasty resembled the Macedonians of the time of Alexander the Great, and these traits are also represented on Greek coins of the archaic style.

Nearly two hundred years later we again meet with this ancient form of skull, but with slight modifications. On the very beautiful sarcophagus from Sidon is represented a battle (? of Arbele) between Macedonians led by Alexander and Persians under Mazaïos, one of the bravest of the generals of Darius. The main differences between the physical characters of these two nations consist in the head of the Persians being higher and the forehead broader and more vertical than that of the Macedonians. The latter were still characterised by a rather low, flat head, by a rather retreating forehead, and often with prominent supra-ciliary ridges and a well-marked nasal notch. The nose of the Persian is very delicate, but inclined to be arched. Their beautiful eyes are more sunken, but less widely open than those of the Greeks. This superb monument has the inestimable advantage of retaining some of its original coloration, and all the Persians, like the Macedonians, had fair or red hair.

FIG. 1.—Coin of Kadphises II., King of the Kushans; circ. 55 A.D.

On the road from Nineveh to Ecbatana is a most interesting bas-relief, carved on the face of a rock by Darius to commemorate his victories over ten kings and princes, whose portraits are carved, and we have portraits of Semites, Persians, a Mede, Magian, Armenian and Sacian. Behind Darius are represented two Achæmenian Persians, who have a gently-curved cranial vault, a high forehead and a curved nose with a slightly flattened tip. The Magian, who is also a Western Persian, is broad-headed. Dolichocephalism is predominant among the Iranians of this period, and more so among the Eastern Iranians.

A gradual transformation of the Persian type was accomplished in the interval between the downfall of the dynasty of the Achæmenids and the accession of that of the Sassanids (*i.e.* from 328 B.C. to 240 A.D.). The heightening and shortening of the head, amongst other characters that affected the old Iranian type, was due either to the slow substitution by a very brachycephalic pre-existing population or to infiltration from neighbouring countries. Ujfalvy points out that the first of these hypotheses is without any historical foundation, although one would expect to find representatives of the alpine race in Iran at that period, so for the present we must rely on the second alternative. We know, from de Sarzec's excavations, that in Babylon in very remote times there was a mixture of races in which a "Turanian" (Ujfalvy) element was present. This transformation of the Iranian type was helped by the arrival of the Arsacian Parthians, who brought heterogeneous peoples in their train.

A study of the coins of the Parthian kings of the dynasty of the Arsaces also reveals an interesting series of changes. The aryanised tatar type of the first three Arsaces was transformed in the fifth Arsace (Mithridates I., 174–136 B.C.) by a mixture of races of which we have historical evidence, and the skull became elongated and flattened; but we find Mithridates III. (Arsace XI.), 60–56 B.C., with a very short and excessively high skull, which was retained till the end of the dynasty in 227 A.D. Nevertheless, all through the series the face was practically unchanged. The Chinese annalist, Ma-touan-lin, says of the A-si (Parthians), "they marry their elder and younger sisters and even their mothers in the same manner as animals," and Lucian uses an identical phrase.

Other alterations of the physiognomy of the Persians were shown in the very aquiline nose, widely open, sunken and almond-shaped eyes. One very typical characteristic of some of the Sassanidan warriors is the great height of the chin, which is still to be seen among the Hadjemis of Persia.

Among the living Tadjiks and Sarts of Central Asia, as among some stocks of Afghanistan and Western Himalaya, we meet, after some 2000 years, with individuals in whom the facial characteristics, and in some cases their crania, remind one of the portrait heads of the Grecian kings of Bactria and India. The low height of the head among the Afghans, of the natives of Kafiristan and of the Dards, the noble profile of the Pandits of Kashmir, are all heirlooms from a remote time. Also the long, well-formed nose of the Tadjiks, their wavy beard and crafty expression of face recall the typical coins of Persian satraps. These latter, as well as the Arsaces and Sassanids, appear to have been leptoprosopic brachycephals, as the unmixed survivors of the old Persians in India are to this day, for, after twelve centuries of exile, the Parsis of Bombay retain these ancestral traits.

When the portrait coins of the Greek kings of Bactria and India are compared, there is no difficulty in seeing a racial resemblance. In the first Bactrian princes the head is low like that of the typical Macedonians, in the later kings it is higher till eventually the head was almost high. The prominent brow ridge of the Macedonians was very persistent, but it, too, was diminished in the last Bactrian kings; the same held good for the marked notch between the forehead and the nose. The prominent, delicate nose of the early Greco-Bactrian kings became short and thick; these princes were almost exclusively leptorhine, and only, last of all, became mesorhine, but were never platyrhine. The chin of the Greco-Bactrian princes was round and full, but less prominent than in the Macedonians or Syrians. There is a fairly regular gradation among the Greco-Bactrian kings when placed in chronological order, not only in the increase of the height of the head, but also in the decrease of the head-length. The face, too, had a tendency to broaden and shorten, for while leptoprosopy was the rule, chamæprosopy was sporadic and was found in only a few of the later Greco-Bactrian kings. Thus it is evident that the purity of the royal family had been impaired by marriages with women of a different stock.

Allusion has been made to Scythians. Certain Asiastic so-called Scythian nations have played an important part in Western Asia, and we must now see what light monuments and coins can throw on the relationships of these much-discussed peoples. The three Scythian groups known as the Sacæ, Kushans and Epthalites constitute an instructive series.

At the time of the Achæmenian kings, the Sacians (Sakas) occupied all the regions between the lower course of the Silis (Iaxartes) and Lake Balkash. "They," says Herodotus, "were in truth Amyrgian Scythians, but the Persians called them Sacæ, since that is the name which they give to all the Scythians." They were renowned for their bravery and wealth and were recognised tributaries of Persia, and formed the advance guard of the empire against the east, as they were settled in the plains of Turkestan almost at the confines of China.

It would appear that even at this time the Sacæ were a mixed race, as, according to the *Chinese Annals*, the Ssé or Sek (who are identified with the Sacæ) originally inhabited Southern China, but they occupied Sogdiana and Transoxiana at the establishment of the Greco-Bactrian monarchy. Towards 165 B.C. they were dislodged from Sogdiana by the Yué-tchi, who themselves were flying before the Hiung-nu. The Ssé thus dispersed invaded Bactriana, chased in their turn from Bactriana by the Yué-tchi in 120 B.C., the Sacians passed over the Paropamisus (Hindu Kush) and directed their steps towards Southern Afghanistan, occupying Sakastan (Seistan to Arachosia); but a century later they were again harassed by

the Yué-tchi, and a part of them, under Maues, founded a kingdom in the Panjab, where they quickly appropriated Hellenic culture.

The Sakas appear to have been mesaticephalic; the height of the head was rather low, they had straight eyes, a well-formed nose, straight, projecting chin. Ujfalvy remarks that they were not true Scythians, as the Aryan element was outweighed in them by another strain. They are nearer to the typical Parthians, but they are not Tatars.

For two thousand years they have persisted, and in the Balti of to-day Ujfalvy recognises the direct descendants of the Sacæ who, about 90 B.C., invaded India from the north over the Karakoram passes, since, in their physical features, the Balti strikingly resemble the effigies on the rock carvings or on the coins of the kings of the Sacæ. The Pamir countries of the Chugnan and Sirikol still retain Sacian linguistic traces.

The Chinese annalists inform us that the Yué-tchi were located in eastern Turkestan, south of the Celestial Mountains, but being invaded by the Hiung-nu in 201 and 165 B.C., they fled to the west and spread over Sogdiana and Bactria, and dispossessed the Ta-hia (Tadjiks). The annalist thus speaks of the inhabitants of Sogdiana: "Sunken eyes, prominent nose and bushy beard, they excel in trade," just like the living Tadjiks. The primitively nomadic Yué-tchi became sedentary and prosperous in this fertile country. In B.C. 25 Kieu-tsieu, or Kudschula, whom the Greeks called Kadphises, the prince of the Kuei-schuang (Kushan), one of the five tribes of the Yué-tchi, conquered the four other tribes, and, crossing the Hindu Kush, invaded

FIG. 2.—Coin of Jayatu Mihirakula (Mo-hi-lo-kiu-lo of the *Chinese Annals*), last King of the Hûnas; 515–544 A.D.

Kophen (Ki-pin of the *Chinese Annals*), the country of the Asascides, and took possession of Kabul. His son Kadaphes conquered most of Northern India, and this empire lasted till towards the commencement of the fifth century of our era. The *Chinese Annals* tell us that Ki-to-lo (Kidara of the coins) chief of the Great Kushans, yielded before the incursions of the Ephthalites, crossed the Paropamisus and settled at Gandhara, in the Valley of Kabul. Towards 475 A.D. the Ephthalites, or White Huns, conquered Gandhara, forcing the Kushans to retire in the Chitral and up to Kashmir. After the defeat of Mihirakula, the last Huna king, the Kushans preserved their power in these regions till the ninth century of our era.

The Kushans appear to have been a brachycephalic folk with a normal head, high forehead, straight eyes, powerful Semitic nose, full mouth, with a somewhat Semitic cast of countenance, but not in the least Mongolian; there was a full beard. These, according to Ujfalvy, are Tatars and not Mongols, the true Scythians of Hippocrates; with Keane ("Man, Past and Present," p. 322) we may call them a Turki people.

They were a gifted and powerful people, and, in consequence of their high political endowments and their adaptability, they played a predominant part alike in Bactria and North-west India, and to a large extent contributed to the formation of the present racial type north and south of the Hindu Kush, and especially so among the Dards of the Himalayan Valleys.

The Hoa or Ye-tha, originally a small people located to the north of the Great Wall of China, were hunted from their territory by the Yuan-Yuan (or Avars?) and fled to the west, and eventually invaded Transoxiana (425 A.D.) and founded a great empire as far as North-west India. The invasion of Europe by Attila (430 A.D.) and that of the Caucasus by the Kidarite Huns were the result of the same pressure of the Yuan-Yuan.

The Hoa sovereigns had the family name of Yé-ta-i-li-to (Ephthalites) which became the name of the dynasty; this was abridged to Ye-tha. Unlike the Yué-tchi they remained nomads, and, as the Chinese annalists inform us, they practised polyandry. Their empire lasted till 557 A.D., when the Tu-kiu (Turks), profiting by the troubles that had fallen on the Hoa or Huna, seized the government. After their defeat, the Ephthalites did not disappear from Turkestan but retired to the east, while another portion mixed with Kushans south of the Oxus.

The Chinese annalists give various interesting accounts of this people. The Hoa migrated with their flocks and did not live in towns. The women took a good standing; brothers took a wife in common, and the women wore a horn on their headdress for each husband that they had. The people were cruel, valiant and bellicose, and had strict laws.

According to the coins the three kings of the Hûnas (the White Huns or Ephthalites of India) were absolutely hairless, the face has a savage expression, the eyes appear somewhat oblique, the nose is large, jaw powerful, neck fleshy, ears immense and in two of the kings recall the legendary pointed ears of Attila. The occipital region of the head is deficient, the vertex being produced into a truncated cone; this remarkable shape must have been the result of artificial deformation, which greatly exaggerated the natural brachycephaly. They are still Tatars, but approach the Mongolian type.

Polyandry was one of the most characteristic traits of the Hoa, and it still persists in the regions which formerly belonged to their empire. The employment of the horned headdress, which was formerly associated with polyandric practices, still exists among the inhabitants of Kafiristan.

There are still many problems awaiting solution among the intricacies of Asiatic ethnology, and it may be that some of the foregoing conclusions will require emendation, but there can be little doubt that the brilliant researches of C. de Ujfalvy have paved the way to a clearer comprehension of the ethnic affinities of various ancient historical peoples, and his papers in *l'Anthropologie*, Tomes ix. (1898) and xi. (1900), and in the *Archiv für Anthropologie*, Bd. xxvi. (1899), are full of references to the labours of his distinguished fellow-workers, Drouin, Percy Gardner, de Lapouge, Maspero, Rapson, Specht, Stein and others.

ALFRED C. HADDON.

THE CURRENTS IN THE GULF OF ST. LAWRENCE.

THE result of investigation of the currents in the Gulf of St. Lawrence, by the Survey of Tides and Currents, has been issued recently in the form of a pamphlet by the Department of Marine and Fisheries, Canada. These investigations were carried on by Mr. W. Bell Dawson, in charge of this Survey, and were made during the summer months of 1894, 1895 and 1896; and they are supplemented by information collected personally by him from captains of vessels, fishermen and others having a long experience in the Gulf. The examination of the currents was made chiefly along the lines of the leading steamship routes which traverse the Gulf. It thus comprises the more open area of the Gulf rather than the estuaries and straits in which stronger tidal streams occur locally.

In the investigations a steamer was employed. It was anchored in positions carefully selected for the purpose in view. These were in all depths, up to 250 fathoms. The steamer thus served as a fixed point from which to observe the behaviour of the current. The observations of the current and of the force and direction of the wind were continuous day and night. Both the surface current and under-currents were investigated, current-meters, registering electrically, being chiefly used for the purpose. Temperatures and densities were also obtained at all depths, to 200 fathoms; and these indications were found of much assistance in tracing the movement of the water. For fuller descriptions of the methods and appliances employed, some of which were specially adapted to the conditions in the Gulf, the reports of progress issued from year to year by this survey must be referred to.

With regard to the general circulation in the Gulf area, the investigations point to its being, broadly speaking, a movement

of rotation in a left-handed direction. It has been proved that there is no great influx of cold water into the Gulf area through Belle Isle Strait, as was formerly supposed. On the contrary, the chief interchange of water between the Gulf and the ocean is at Cabot Strait, the wider entrance to the Gulf south of Newfoundland.

We cannot enlarge further on these interesting results, as the information as now published is in as concise a form as it can be put. We desire, rather, to draw attention to some points which the investigations themselves emphasise, and which are of general application elsewhere in similar work.

The most important of these is the relation of the under-currents to the current on the surface. These were examined everywhere, to a depth of 30 fathoms at least, as this depth extends almost uninterruptedly over the whole Gulf area. It may be thought, at first sight, that the direction of the under-current has no bearing upon the movement of the water as it affects navigation. In such a region as the Gulf of St. Lawrence, however, the currents in the summer months are all very moderate in their speed, usually ranging from half a knot to one knot per hour; and their direction on the surface is accordingly much influenced by the wind. It was found in these circumstances that the movement of the under-current at 20 or 30 fathoms often showed more definite characteristics; as, for example, a tendency to make constantly in some one direction, or to vary with the tide. The wind is thus a disturbing element; and the under-current, being more in accordance with the normal conditions of the locality, will come up to the surface as soon as the disturbing influences which have been acting on the surface of the water cease to operate.

It may be unfortunate, from the point of view of the navigator, that it is the surface of the water to a depth of 5 or 10 fathoms which is so readily and so frequently disturbed; but, on the other hand, it is clear that it is essential to make a careful investigation of the under-current in order to understand the surface current itself. The study of the under-current is also necessary, if any hope is entertained of arriving at the general circulation in the Gulf or the true relation of its currents to the causes which influence them.

When a period of some length is considered as a whole, and the under-current is also taken into account, it becomes possible to trace the general circulation of the water; which depends upon a greater movement in some dominant direction rather than in other directions, when long averages are taken.

The primary tendency in the surface current is thus to follow the direction which the general circulation has in the locality in question; but this tendency is disturbed and often overcome by the influence of the tide and wind. The tidal influence shows itself chiefly as a veer in the direction of the current, which is either through a limited range or completely around the compass; and it is also probable that the tides themselves are irregular in some localities, owing to interference. When the wind remains in one quarter and has any considerable strength, the drift which it gives to the surface water soon extends to a depth of five fathoms or more, and its influence thus makes itself felt throughout the thickness of the surface layer which affects shipping. As a rule these influences are all acting at the same time; and it is their combined effect which gives rise to the actual behaviour of the surface current.

A knowledge of the general circulation is also important to mariners, as it includes all the more constant currents, and it shows the direction which the surface current tends to take when undisturbed. Although there are few instances of currents in the Gulf area which run steadily enough to be termed constant, we have yet found it possible, from continuous observation or long experience, to arrive at a dominant direction for each locality; or the direction in which the current runs more frequently, and in which, therefore, the water makes on the whole.

With regard, also, to the drift of ice as an indication of the set of the current, a superficial view may readily be taken; but it is here pointed out that to infer correctly the set of the current it is necessary to distinguish between the different kinds of ice met with and their relation to the movement of the surface of the water and to the under-current, respectively.

This is illustrated by the character of the ice met with in the Gulf of St. Lawrence, which is of three kinds:—(1) Berg ice, or true icebergs, found in the vicinity of the straits opening into the ocean. (2) Flat or pan ice, forming fields or in broken pieces, usually not more than 6 feet in thickness, but sometimes as thick as 10 feet. This often jams or shoves along the shore or between islands, and may form masses 20 feet or more in thickness, but it can never be mistaken for berg ice. (3) River ice, from the St. Lawrence River and its estuary. This is also flat ice, but it can be readily distinguished by its appearance from the Gulf ice.

The berg ice, from its great depth in the water, will evidently move with the under-current; and it will not be appreciably affected by the wind. These bergs do not necessarily indicate the direction of the current as affecting shipping, except when the surface current has also the same direction. They show in reality the average direction the current has between the surface and the depth of their draught. This draught is limited to about 30 fathoms by the depth of the Belle Isle Strait. They are thus of much value as an indication of the general movement or circulation of the water.

The relation of the flat ice to the wind and current requires some little consideration. It is, of course, just as true of this ice as of the berg ice, that the greater part is under water; but, as it is almost always in broken pieces, more or less piled and with upturned edges, the wind has a much greater hold upon it, in proportion to its total weight, than on the berg ice. Even when this is allowed for, its depth in the water still gives the current a greater hold upon it than the wind has. For example, if such ice is drifting with a current in a given direction, and the wind is blowing across that direction at right angles, the ice will seldom be set more than two points, or three at the most, off the true direction of the current. When the ice becomes soggy or water-soaked and loses its edges, as it does later in the spring, it will set still more correctly with the current.

When the surface current itself is moving in the direction of long-continued or prevalent winds, as it often does in the Gulf, the flat ice naturally follows the same direction too. Also, in regions where the current is tidal, and the ice in calm weather would drift as far in the one direction with the flood tide as in the other direction with the ebb, the direction in which it makes, on the whole, will depend upon the wind. It is probably for these reasons that it is so often said that the ice drifts with the wind; although this merely expresses the fact, without distinguishing between the relative influence of the wind and the current upon it.

There is also a direct effect which the ice has upon the strength of the current in regions where the direction of the surface drift is under the influence of the wind. The broken and upturned edges of the ice give the wind a much greater hold upon the water than it otherwise would have. Hence during long continued winds the speed of the current is appreciably greater than if the ice were not present. This is undoubtedly the explanation of the common belief which is expressed by saying that "the ice makes its own current." It may be well to recall that the weight of the ice itself is the same as the water which it displaces; and, therefore, the wind has no greater mass to set in motion in producing a surface current than if the ice were to melt and refill the hollow which it makes in the water; yet the presence of the ice gives the wind a better hold than it would have upon the surface of open water free from ice.

There is one condition of the ice which may prevent it from showing correctly the movement of the water. When it is set against an island or headland and packed together for a long distance out, with open water beyond, it may circle round as on a pivot. The outer edge of the pack may thus make a long sweep very different in its path from the true set of the current; and its movements also become irregular, as vessels caught in such ice which are near together in the evening may be ten or fifteen miles apart in the morning.

The influence of rivers flowing into such a land-locked area as the Gulf of St. Lawrence is also discussed, with approximate measures of volume which show how small the volume of even such a river as the St. Lawrence is, relatively to the water in motion in a costal current, which is more nearly comparable with an ocean current.

The probable balance of flow between the Gulf and the ocean is also explained, but measurements of volume of even an approximate kind are wanting to give precision to the results. The importance of such investigations with regard to the movements of fish, which must be influenced by the temperature of density of the water, is also emphasised, in view of the large annual value of the Canadian fisheries.

The further investigation of the currents has been discontinued since 1896 for reasons of economy; but the tides themselves are receiving careful attention, and already trustworthy tide-tables

are issued by the Survey for the more important Atlantic harbours, as well as for the Pacific coast of Canada. The tides are complicated by a great variation in range, and the observations secured will serve also as a basis for future investigation of the currents, many of the strongest of them being tidal in their nature.

THE ABSORPTION SPECTRA OF SALINE SOLUTIONS.

IN the *Scientific Transactions* of the Royal Dublin Society (vol. vii. series ii. pp. 253–312), Prof. W. N. Hartley gives the results of a long series of experimental investigations which he has undertaken to determine the action of heat on the absorption spectra and chemical constitution of saline solutions. After reviewing previous researches by Schœnbein, von Babo, Schiff, Gladstone, Bunsen, Melde, Burger, Vogel, Landauer, Morton, Bolton and Russell, the author gives a description of his mode of experimenting. Wedge-shaped cells containing the liquids under examination were heated in an air-bath with glass sides. The sources of light used were sunlight and an argand burner fed with oxygen.

Then the absorption spectra of solutions of the salts of nickel, copper, cobalt, chromium, uranium, didymium, and various permanganates are described, with details of the measurements, accompanied by drawings from, or reproductions of, the photographed spectra. Much of the discussion is directed to the bearing of the spectral evidence as to the constitution of the solutions, and the following conclusions indicate the results arrived at:—

(1) The absorption spectra of different salts of the same metal, whether solid or in solution, are not identical, even when the spectrum is a marked characteristic of the metal.

(2) When a definite crystalline hydrate dissolves in a solvent which is not water, and is not a dehydrating agent, the molecule of the salt remains intact.

(3) In any series of salts which are anhydrous, and which do not form well-defined crystalline hydrates, the action of heat up to the temperature of 100° C. does not cause any further alteration in their absorption spectra beyond that which is usual with substances which undergo no chemical change by such rise of temperature. The change is usually an increase in the intensity of the absorption, or a slight widening of the absorption bands.

(4) As a rule the crystallised metallic salts, in which water is an integral part of the molecule, dissolve in water at ordinary temperatures without dissociation of the molecule.

(5) Crystallised hydrated salts, dissolved in a minimum of water at 20° C., undergo dissociation by rise of temperature. The extent of the dissociation may proceed as far as complete dehydration of the compound, so that more or less of the anhydrous salt may be formed in the solution.

(6) The most stable compound which can exist in a saturated solution at 16° or 20° C. is not always of the same composition as the crystalline solid at the same temperature, since the solid may undergo partial dissociation from its water of crystallisation when the molecule enters into solution.

(7) Saturated solutions of hygroscopic and deliquescent salts combine with water when diluted to constitute molecules of more complex hydrated compounds in solution.

(8) When a saturated solution of a coloured salt undergoes a great change of colour upon dilution, or any remarkable change in its absorption spectrum due to the same cause, the dilution is always accompanied by considerable evolution of heat.

CONFERENCE OF SCIENCE MASTERS IN PUBLIC SCHOOLS.

WHILE carrying out the important work of spreading scientific instruction in this country, our educationists should make themselves quite sure that the teaching already inaugurated is what it claims to be. Care must be exercised in order that a training in habits of exactness and observation is imparted, as well as an appreciation of the principles of science quite apart from a mere knowledge of facts. By intelligent practical work upon the part of the individual scholar this alone can be attained, and under present circumstances such exercise is difficult to successfully organise in schools.

Expensive laboratories and able masters are of no avail if the necessary conditions be not introduced. The scientific staffs of our large public schools are fully aware of their responsibility to the nation, and what is lacking to enable them to fulfil it. It might, therefore, be thought that they would have been the very first to advocate the necessary changes, but their position, it will be seen, is such a peculiar one that, without strong general feeling behind them, their trouble would be all thrown away.

With the dawn of the new century, however, and in view of the present agitation for an improved system of scientific education, the public school science masters have combined all their energies for the attainment of that end. On January 19, therefore, a conference was held at the rooms of the University of London, and was attended by a thoroughly representative body of men. Sir Henry Roscoe, Vice-Chancellor of the University, and a member of the governing body of Eton College, occupied the chair, and explained the importance of the action taken.

Among the papers read, that by Mr. Oswald H. Latter, of Charterhouse, contained perhaps the most general observations. "Science teaching," he told us, "was first introduced into our public schools as a sop to a growing public opinion, and with a desire to impart a gentlemanly acquaintance with scientific matters. The broad-minded persons who ventured on this new departure imagined, unfortunately, that the admirable mediæval methods of classical and mathematical teaching were equally well suited to the new comer, who, however, had to be content with a very small portion of the temporal possessions of its elder bretheren." Mr. Latter then urged the necessity of a scientific education for future legislators, and our commercial and professional men, and from a national point of view. Form teaching would do much, he considered, to remove the incubus of ignorance and apathy in the coming generation, the following being his recommendations with regard to it:—

(1) Science should be raised to the dignity of a "form subject," and no longer be regarded as a more or less negligeable extra. It should enter for at least one hour into the ordinary work of every day, and claim, at any rate, some portion of the time devoted to preparation. There must be some lopping of the old branches of education if good fruit is to be borne by the engrafted scion.

(2) A classification according to proficiency in science throughout the school.

(3) At least half, and with lower forms more than half, of the allotted hours should be devoted to systematic laboratory work in the elements of physics and chemistry.

(4) The teaching should be continued to the sixth forms instead of being deliberately withheld from them as is so often the case, a distinction which at once narrows the intellectual horizon of the ablest boys in the school, and degrades the subject in the eyes of the remainder.

Mr. E. E. Ashford, of Harrow, would with very good reason teach some physics before chemistry, and, if possible, elementary biology before either, for, he said, let us first use the facts a boy knows to teach the methods of science. All boys, he continued, are acquainted with many bits of natural history, and its general laws were more easily appreciated than the more exact ones of the other sciences. The paper by Mr. Ashford concluded with the following resolution, which found favour with the meeting, viz., that "it is essential that every boy before leaving school should go through a course of practical measurement and experiment involving no previous theoretical knowledge."

Prof. Armstrong, who was present, true to his tenets that academic words should not be used in schools, suggested nature-study in place of biology, but the terms were not recognised as synonymous by several speakers, and so he was somewhat misunderstood. Mr. A. Vassall, in describing the work at Harrow, recommended that the biological lessons should form a continuous course, and it must be remembered that the boys (over fourteen and under sixteen years of age) he teaches are not tiny children for whom unconnected object-lessons are best adapted. The list of lessons given to the conference well illustrated Mr. Vassall's plea for the "judicious skipping" of subjects not quite suitable for introductory work. Mr. Cumming, of Rugby, used, he said, to teach all his boys botany; he owned, however, that he had no qualifications but a love of the subject, and it is not surprising that the other sciences he has since substituted have succeeded better.

Mr. W. D. Eggar, of Eton, pointed out that, owing to external pressure, many public schools had started elementary

physical measurements for small boys, following Board School methods; but that in the latter institutions mathematical and science teaching were continuous, the same master teaching both to the same boys. In public schools the two subjects are kept separate. Much of what is now taught in the laboratory could more usefully be acquired in mathematical class-rooms with all the necessary apparatus. Mathematics would gain enormously, and much valuable science time be saved. Here Mr. Eggar submitted that he was only urging the adoption of practical mathematics which Prof. Perry had long advocated, and without opposition, but also without any visible effect upon the universities, which still, among other things, demanded a modicum of unapplied and undigested algebra. Sir Henry Roscoe bore out what Mr. Eggar had said, and proposed that a meeting of mathematical masters should be held, at which Prof. Perry might possibly convince them. Speaking as a mathematical master, Mr. Hurst, of Eton, cordially agreed with the views of Prof. Perry and Mr. Eggar; he stated, however, that limited time and the requirements of the universities utterly forbade their adoption in his own case. Another point emphasised by Mr. Eggar was that trigonometry mechanics should be introduced at an earlier stage into the teaching of mathematics, and his resolution that "some knowledge of physics should be required of all candidates for a university degree," was carried unanimously.

The universities came in also for a good deal of criticism, among other examining bodies, from Mr. C. Falkner, of Weymouth. Their entrance science scholarships cause boys to specialise while too young, and before they have got a sound foundation upon which to base their education. No college seems to require the same scope of science, and this necessitates what amounts to the private coaching of every boy in the scholarship class of a public school. Mr. Falkner had some very good suggestions to make for the improvement of these and army examinations, and repeated the plea that is now finding much favour, that teachers and examiners should meet and work together.

The paper by Mr. W. H. Lewis, of Exeter, was not discussed, owing to the author's absence. It dealt with the desirability of longer hours and smaller classes, and larger staffs. The difficulty which a "literary" head-master has of realising the peculiarly laborious nature of science teaching where complicated apparatus has to be fitted up was also alluded to.

An interesting survey of the work of school natural history societies was to be found in the address by Mr. A. Vassall, of Harrow, and the discussion upon it. Many advantages were claimed for the subjects involved, from the education of future landowners and travellers as well as for the boys at school. The sectional system, which divides workers up into groups according to their study, was advocated. Compulsory games very often spoiled matters, and individualism, Mr. Vassall very rightly pronounced, was thereby extinguished. Public opinion among the boys and the standing aloof of those with influence, as well as the apathy of many masters, were also cited as obstacles in the way of field work at schools. Nevertheless, quite a number of successful societies at present exist.

Many suggestive methods of actually dividing up the time for teaching were given by various members of the conference; but, one takes it, the most useful purpose it will serve is to bring before head-masters, governors of schools, and examining bodies the results of the experience and the serious recommendations of a body of picked scientific men whose hearts are in their work.

WILFRED MARK WEBB.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

THE annual meeting of the Association of Technical Institutions will be held on Tuesday, January 29, in the Fishmongers' Hall, London. An address will be given by Sir W. Hart Dyke, Bart., M.P.

WE learn from *Science* that Dr. D. K. Pearsons has given Colorado College 50,000 dollars, promised some time since, and it is reported that he has given Northwestern University 30,000 dollars for the erection of a woman's dormitory, and 200,000 dollars to an educational institution, the name of which is not to be made public during his life time. It is believed that Dr. Pearsons' gifts to educational institutions amount to three million dollars.

SCIENTIFIC SERIAL.

THE *Journal of Botany* for January contains a useful paper by Mr. Arthur Lister on the cultivation of the Mycetozoa from spores. Mr. George Murray and Mr. C. Bucknall contribute a discussion on the question whether the box, *Buxus sempervirens*, is a native of Britain. They conclude that this is unquestionably the case with the locality near Wootton-under-Edge, an adjacent farm having been known as "Boxwell" for at least seven centuries. This increases the probability of the shrub being indigenous also in other localities, including Boxhill, near Dorking. Mr. W. Carruthers and Miss A. Lorrain Smith have a paper on a disease in turnips caused by bacteria. Prof. Potter has named the bacterium *Pseudomonas destructans*.

SOCIETIES AND ACADEMIES.

LONDON.

Geological Society, January 9.—J. J. H. Teall, F.R.S., President, in the chair.—The geology of South-Central Ceylon, by John Parkinson. In this communication the author endeavours to give some account of the relations between the various granulitic rocks of Ceylon. A series of more or less isolated sections were studied, the rocks in each considered under separate heads, and conclusions put forward relative to the whole.—Note on the occurrence of corundum as a contact-mineral at Pont-Paul, near Morlaix (Finistère), by A. K. Coomára-Swámy. The intrusive granite of Pont-Paul, near Morlaix, contains highly altered fragments of sedimentary rock. The minerals found in them are biotite, muscovite, corundum (first recorded by Prof. Barrois in 1887), plagioclase, andalusite, pyrite, magnetite, sillimanite, green spinel, and zircon.

Mathematical Society, January 10.—Dr. Hobson, F.R.S., President, in the chair.—Prof. Love, F.R.S., made a communication on streaming motions past cylindrical boundaries. Mr. Basset, F.R.S., also spoke on the subject.—Mr. Campbell read a paper entitled "A Proof of the Third Fundamental Theorem in Lie's Theory of Continuous Groups."—The President communicated a paper by Mr. E. W. Barnes on the zeroes of Bessel's functions, and a paper on some cases of the solution of $z^{p^n-1} \equiv 1$, mod. p, by Prof. F. S. Carey.

Zoological Society, January 15.—Prof. G. B. Howes, F.R.S., Vice-President, in the chair.—Mr. W. E. de Winton exhibited and made remarks on a skin of the large grey Cynictis (*Cynictis selousi*), obtained by Mr. P. C. Reid on the west bank of the Linyanti River, South Africa. The species had been described from a skull only, from Bulawayo, and the skin of the animal had previously been unknown to naturalists.—Mr. O. Thomas exhibited, on behalf of Mr. R. Lydekker, a specimen of the skull of a common fox (*Canis vulpes*) with two upper canines on each side of the jaw.—In describing the collection of fishes brought home from Lakes Tanganyika and Kivu by the Tanganyika Exploring Expedition, under the leadership of Mr. J. E. S. Moore, Mr. G. A. Boulenger pointed out that the study of this important collection did not modify the conclusions embodied in his first report published in 1898. The exploration of Lake Kivu had thrown no light on the origin of the Tanganyikan fauna; the smaller lake proved to be very thinly populated with fishes, which all belonged to widely distributed genera, the species showing a mixture of Nile and Tanganyika elements, with two that might prove to be endemic. The list of the fishes from the two lakes comprised 91 species, 74 of which had been named by the author. The collection now described consisted of examples of 50 species, 26 of which were new to science, 2 being made the types of additional genera of the family *Cichlidae*.—Mr. G. A. Boulenger read a paper on a collection of freshwater fishes made by Dr. W. J. Ansorge in the Niger Delta. The collection was described as one of exceptional interest. One of the two new genera, for which the name *Phractolaemus ansorgii* was proposed, constituted the type of a new family (Phractolæmidæ), intermediate between the Osteoglossidæ and the Clupeidæ. The second new genus, *Polycentropsis*, belonged to the Nandidæ, a family new to Africa; its position was regarded as near the South American *Polycentrus*. A new *Gnathonemus* and three new *Pelmatochromis* were also described.—A communication was read from

the Rev. O. Pickard-Cambridge, F.R.S., containing an account of some new and interesting spiders collected in South Africa by Mr. G. A. K. Marshall, and in the Malay Peninsula and Borneo by Mr. R. Shelford.—Mr. F. E. Beddard, F.R.S., contributed a fourth instalment of his notes on the anatomy of Picarian birds, which contained an account of the skeletons of the ground-hornbills (*Bucorvus cafer* and *B. abyssinicus*) and notes on other species of hornbills.—A communication from Dr. A. G. Butler contained notes on and a list of the butterflies recently collected by Captain H. N. Dunn on the White Nile.—Dr. F. G. Parsons read a paper on the muscles and joints of the giant golden mole (*Chrysochloris trevelyani*), based on an examination of three specimens of this animal. The author found that previous observations, which hıd been made on less material, though mainly correct, were somewhat inaccurate in details.

Entomological Society, January 16.—Annual Meeting. Mr. G. H. Verrall, the President, in the chair.—It was announced that the following had been elected officers for the session 1901–2. President, the Rev. Canon Fowler; Treasurer, Mr. R. McLachlan, F.R.S.; Secretaries, Mr. Herbert Goss and Mr. H. Rowland-Brown.—The President referred to the losses the Society had sustained during the past session by the deaths of Mr. Spence, the Baron de Selys-Longchamps, Mr. Blatch, Major G. Cockle, Mr. P. Crowley, Lord Dormer, Mr. J. H. Leech, Dr. W. H. Lowe, Prof. Joseph Mik, Prof. Emile Blanchard, Dr. Staudinger, and other entomologists. He then delivered an address, in which he dealt chiefly with the abuses and errors which have crept into entomological nomenclature and the reckless manner in which types of various genera are described from single specimens, without careful study of the many forms which a single insect may assume even in a limited locality. He especially deprecated the publication of supposed new species or varieties before their identity had been certainly established, where the object of the author was to claim something more than a contribution to material for determination. In the vexed problem of priority in nomenclature, he expressed himself all in favour of retaining distinctive names only when such names were neither offensive to good sense nor grammar, and cited instances in which a printer's error was still received as orthodox, while the obvious and original name given by the inventor was rigorously discarded. Lastly, in reply to those who have questioned the value of entomology as a science, he mentioned several amusing instances of what an experienced entomologist might do in the way of turning his knowledge to practical account. Commentators on the work of the late Robert Louis Stevenson were unable, but anxious, to discover whether the notes made by him in a certain book were written before or after he had taken up his residence in Samoa. A fly which had been squeezed between the pages settled the question, for Mr. Verrall at once pronounced the remains as those of an insect peculiar to the Polynesian islands.

Institution of Mining and Metallurgy, January 16.—Mr. A. G. Charleton, Vice-President, in the chair.—Notes on mine surveying, by G. A. Troye. In this paper the author refers chiefly to the practice in the Transvaal, and briefly describes the methods employed there. He aims at a high standard in a mine surveyor, who, he thinks, in addition to essential requirements, should be expected to be a competent geologist, with a thorough knowledge of the occurrence of ore deposits, their dislocations, &c. He considers that it is to him the management should appeal in cases of disturbed ground, and he, more than any one, should be able to quickly find a lode lost through displacement, and should be held responsible for the proper development of a mine. Numerous examples explain the different forms of calculation. Stress was laid upon the necessity of checking all survey work most carefully, and to attain this the co-ordinates are always calculated by the author from two sides of a triangle in order to obtain independent results. The traverses are calculated by inverse multiplication of the natural sines and co-sines of the angles of direction or bearings. A strong point is made in the paper of the desirability of having substantial permanent bench-marks both above and below ground, the latter being labelled with a numbered tin ticket. This, the author says, has proved of great advantage to the mine-manager, sampler, &c., and facilitates work of all kinds, especially when a change of staff takes place. Many useful hints are given as to conducting a survey, keeping the field-book and calculating results.—Paper on electro-silvered *versus* plain copper plates, by Edward Halse. In this paper the author deals with the question of the use of electro-silvered plates in gold milling in preference to plain copper plates, and quotes in support of his view various works on the metallurgy of gold. An important question to the millman is whether silvered plates extract more gold from the crushed ore, and the author is convinced from experience that this is the case and that therefore silvered plates should supersede plain copper plates in gold milling. He gives numerous tables of results in support of his view, and the paper contains much useful information. In the discussion it was pointed out that in many cases the percentage of gold extracted was low in consequence of the failure of the millman to keep his plates clean, and the importance of the increased use of "elbow-grease" rather than chemicals was strongly emphasised.—Note on an improved native gold-mill, by the same author. The note gives details of an improved mill worked by overshot water-wheel erected by the Colombian Mines Corporation at Antioquia, Colombia, where the water supply was much in excess of requirements.—Note on the geology of Lake Nyasa, by Alexander Richardson. The author describes Lake Nyasa as a sheet of clear water some 360 miles in length by from 14 to 40 miles in width, lying at an altitude of 1500 feet, its deepest part being 1000 feet below sea-level. After describing the geological formations he goes on to say that whilst as yet no valuable minerals have been discovered in British Central Africa, half-caste Portuguese at one time worked alluvial gold between the Angoni country and the Zambesi, and gives it as his opinion that workable gold will be found in the mountainous region to the west. For half the year the climate is wet and malarious and for the other half dry, cool and healthy.

Royal Meteorological Society, January 16.—The President, Dr. C. Theodore Williams, in the chair.—Annual General Meeting.—Reference was made to the celebration of the Society's Jubilee on April 3–4 last, and also to the death of Mr. G. J. Symons, F.R.S., who had amongst other things bequeathed to the Society about 2200 volumes and 4000 pamphlets from his valuable library.—Dr. C. Theodore Williams delivered the presidential address, taking for his subject the climate of Norway and its factors. He considered that its meteorology should prove an attractive study for the Society as having much in common with that of our country, both the Norwegian and the British shores being influenced by the same Gulf Stream, and having their winters and summers tempered by the same equalising agency. The factors which influenced the climate were: (1) the insular character of the country; (2) the distribution of the mountain ranges, which explains to a large extent the rainfall; (3) the waters of the ocean, which, from a variety of circumstances, come into close connection with much of the country and thus temper extremes of climate; and (4) the sun, which in this latititude remains in the summer long above the horizon, and in the winter long below it. The address was illustrated by a large number of lantern slides of Norwegian scenery, embracing mountains, glaciers, fjords, &c.—The election of officers and council for the ensuing year then took place, Mr. W. H. Dines being appointed president, and Dr. C. Theodore Williams treasurer.

Linnean Society, December 20, 1900.—Prof. S. H. Vines, F.R.S., President, in the chair.—Mr. B. Daydon Jackson exhibited two editions of Hill's "Flora Britannica," the earlier, of 1759, being apparently unknown to bibliographers. This edition differs from the usual issue of 1760 in having a different title-page, and publisher's name: the copy exhibited wants the plates mentioned on the title. The species ascribed to the genus Statice are three in number; in modern nomenclature one species of Armeria and two of Statice.—Prof. Howes, F.R.S., exhibited a couple of pigeon's egg-shells, cast up at the mouth by the tropical African egg-eating snake *Dasypeltis scabra*, now living in the Zoological Society's Gardens, and called attention to the presence of a series of spiral and longitudinal fracture-lines, pointing to an elaborate co-ordinate muscular activity in the "crushing" process, the probable nature of which he discussed, in the light of the recent investigations of Katheriner into the anatomy of the animal and the observations of Miss Durham upon its feeding habits.—Prof. Poulton, F.R.S., exhibited a living specimen of the death's-head moth (*Acherotia atropos*), and proved with a stethoscope that the late Prof. Moseley was correct in stating that the sound comes from the proboscis. He also showed that all sound ceased the moment the tip of the

straightened proboscis was dipped in water, and could not be resumed until the organ was withdrawn; thus supporting Prof. Moseley's opinion that the sound was produced by forcing air through the proboscis. Prof. Poulton also exhibited projected photographs of *Acraea unicolor* var. *alcippina* recently received from Sierra Leone by Mr. Herbert Druce, together with specimens of *Limnas chrysippus* var. *alcippus*, which they closely resemble. He showed that this Acræa is represented in the South and East Central regions of Africa by varieties which correspond to the respective forms of *L. chrysippus*; that in fact the geographical coincidence between the two is much closer than with the forms of the female of *Hypolimnas misippus* and those of *L. chrysippus*. The former is one example of Müllerian mimicry, both forms being independently distasteful; while the female Hypolimnas is generally regarded as a Batesian mimic.—Mr. Arnold T. Watson read a paper on the structure and habits of the Ammocharidæ, a group of marine Polychæte worms which inhabit sandy localities and are protected by tubes of unique structure.—Mr. I. H. Burkill read a paper on the flora of Vavau, a little known island of the Tonga group, on which some remarks were made by the President.

PARIS.

Academy of Sciences, January 14.—M. Fouqué in the chair.—The President announced to the Academy the death of M. Ch. Hermite, member of the Section of Geometry, and of M. Adolph Chatin, member of the Section of Botany.—On the theory of precession, by M. H. Poincaré. The secular variations of the terrestrial equator, as determined by Stockwell, lead to an entirely different coefficient from that obtained by Backlund using the method of Gylden. It is shown on analysis that the coefficients obtained by Stockwell are correct, there being a fundamental error in the method of Gylden.—Researches in the formation of organic sulphur compounds, by M. Berthelot. A study of the thermal properties of the mercaptans, the heats of combustion and formation of ethyl mercaptan, ethyl sulphide, amyl mercaptan, amyl sulphide, and allyl sulphide being given.—New researches on the isomerism of the sulphocyanic ethers, by M. Berthelot. Measurements of the heats of combustion and formation of phenyl isosulphocyanide.—The gaseous products disengaged by the action of heat from some igneous rocks, by M. Armand Gautier. Granites from different sources were heated in a vacuum with syrupy phosphoric acid, the gas evolved measured and analysed. The quantities found were very considerable, varying from 560 c.c. to 5438 c.c. per kilogram. The gases found consisted of sulphuretted hydrogen, carbon monoxide and dioxide, methane, hydrogen, nitrogen and argon. From analyses of the gases given off at different stages, it is shown that the gases are not simply stored up in the rock, but result from reactions at the temperature of the decomposition.—On the effects of the substitution of alcohol for sugar in food upon muscular action, by M. A. Chauveau. The question as to how far alcohol can replace sugar in a mixed diet is of considerable physiological interest, the question being attacked by means of the respiratory coefficient. As a net result of a lengthy series of experiments upon a dog, it is concluded that the alcohol introduced, although very rapidly absorbed by the organism, only participates to a very small extent, if at all, in the combustions from which the muscular system draws the energy necessary to its working. The alcohol is not an energy producing food, its introduction into a food having rather the opposite effect.—On the new Giacobini comet, by M. Perrotin.—On quadruply periodic functions, by M. Georges Humbert.—On orthogonal systems admitting of a group of Combescure transformations, by M. D. Th. Egorov.—On the correlation of the experiments made at Dijon in 1894 for the application of the idea of a common return for telephonic circuits, and on experiments made since 1894 on telephony without wires, by M. Rheins.—Action of hydrogen upon bismuth sulphide, by M. H. Pelabon. The action between hydrogen sulphide and bismuth is a reversible one, and has been studied experimentally by the author at a temperature of 610° C. Three reactions were studied, hydrogen and the sulphide of bismuth, hydrogen sulphide and bismuth, and hydrogen with a mixture of sulphur and bismuth.—On the chlorobromides of thallium of the type $TlX_3 3TlX$, by M. V. Thomas.—On the combinations of the chlorides of phosphorus with boron bromide, by M. Tarible. Bromide of boron in presence of the chlorides of phosphorus react with great facility to form double compounds. These bodies, which are well crystallised, are decomposed by cold water, by chlorine, and by ammonia.—On the new mode of preparing hydrated sodium peroxide, and their properties, by M. George F. Jaubert. Although sodium peroxide when treated with water is decomposed into oxygen and caustic soda, if treated with moist air free from carbonic acid, no decomposition takes place, water being absorbed and hydrates formed. Hydrated sodium peroxide is stable in the cold, and may be kept for six months without appreciable alteration.—Determination of the latent heats of vaporisation of some substances in organic chemistry, by M. W. Louguinine. Figures are given for aniline, methylethylacetoxime, anisol and butyronitril.—Study of uranium nitrate, by M. Œchsner de Coninck. Determinations of the densities of solutions of uranium nitrate in nitric and sulphuric acids.—The oxidising action of ammonium persulphate upon some immediate principles of the organism, by M. L. Hugounenq. A study of the oxidation of uric acid, bilirubin, hematin and blood by ammonium persulphate.—On the structure of the vascular plants, by M. G. Chauveaud.—On the occurrence of a mineral smelling of free fluorine at Beaujolais, by M. Jules Garnier.—On the Neomylodon and the mysterious animal of Patagonia, by M. André Tournouër.

THE SCIENCE OF SPECTRUM ANALYSIS.

Handbuch der Spectroscopie. By H. Kayser. Professor of Physics at the University of Bonn. Vol. i. Pp. xxiv + 782. 251 figures. (Leipzig: Hirzel, 1900.)

THERE are comparatively few men of science who can accurately handle a spectroscope and interpret its indications with assurance. The number of chemists, for instance, who could look at the spectrum of a Geissler tube, and pick out at once the lines of hydrogen, oxygen, nitrogen or carbon, is probably very small. No one denies the importance of the spectroscopic method, but its practice requires so long an apprenticeship and so severe a training, while the experimental facts are so numerous and the pit-fâlls so plentiful, that the physicists and chemists are inclined to shirk the whole subject and to leave it to the few who happen to have been brought up in a spectroscopic atmosphere.

Part of the cause of this apparent neglect is due to the want of a proper guide to lead the willing but bewildered student through the intricacies of a most diffuse and uninviting literature. We possess only a few short text-books which are quite insufficient for any serious requirements, and various catalogues of papers relating to spectrum analysis which have proved absolutely useless. Prof. H. Kayser, well known as an authority on the subject, has undertaken what must prove to be the work of a lifetime. The first volume of his "Treatise of Spectroscopy" is now completed and will be welcomed by all who desire to know, as well as by those who already know, something of this branch of science.

This volume covers 750 pages and deals, after an historical introduction, with the instrumental methods of producing and examining spectra. There can be only one opinion on the admirable manner in which Prof. Kayser has accomplished his task. He has succeeded in giving a clear and complete account of his subject, and at the same time avoided overburdening his book with details, which the reader can always find in the original papers, to which complete references are given.

The first 120 pages are devoted to the history of the subject, which is dealt with in a fair and impartial spirit. The early papers, in which ideas, *now* so obvious to us, are present in a vague and intangible form, are fully dealt with, but we naturally turn to the exciting time when Kirchhoff and Bunsen finally disposed of all vagueness and created the science of spectrum analysis. Questions of priority never remain long in an acute stage, and no one would now detract one tittle from Kirchhoff and Bunsen's merit because others may have had some correct ideas before them. Balfour Stewart came very near the truth, but it is very doubtful whether, even if his treatment of the relation between absorption and emission had been as rigid and conclusive as that of Kirchhoff, he would have carried the scientific world with him in the way the Heidelberg philosophers did. In fact, only a small fraction of the chemists and physicists who hailed the new discovery with delight could possibly have appreciated Kirchhoff's mathematical deductions. Even making full allowance for the fact that most men are more easily convinced by an argument which is entirely beyond their comprehension than by one which they partially understand, I cannot believe that the turning point in the history of spectrum analysis lay in Kirchhoff's theoretical proof of the cause of the reversal of the bright lines. The most interesting portion of the history of science lies, to my mind, not so much in studying the evolution of clear ideas from vague forebodings of truth (though that, no doubt, is of great importance), as in tracing the particular theoretical argument or experimental fact which carried conviction. In this respect, I should give the foremost place in the history of spectrum analysis to Kirchhoff's experiment, in which he actually obtained the reversal of the sodium and lithium lines, and I should give almost equal value to the clear insight and experimental skill which allowed Kirchhoff and Bunsen to assign the D lines with certainty to sodium alone. For the ubiquitousness of these lines was one of the great stumbling blocks which had prevented every real advance, by suggesting that different elements might emit the same vibrations. Even those who had recognised that the yellow lines owed their origin to the presence of a sodium salt had failed to realise that the salt itself was decomposed, and that the lines were due to the metallic element.

There is an interesting incident connected with this point which may be mentioned here, though private conversations, unconfirmed by documentary evidence, have no real value in questions of history. The late Prof. Balfour Stewart assigned his own failure to carry his researches to their logical conclusion to his ignorance of the fact that salt was decomposed in the flame. He made an experiment to see whether rock-salt exercised a selective absorption for light emitted by a sodium flame, and failing to discover such an absorption put the matter aside. But I have been carried away by old recollections, and must pass on from Prof. Kayser's first chapter, which carries the history of the subject to Zeeman's discovery, and the Baltimore experiments on the influence of pressure.

The second chapter deals with the methods of producing luminous vapours. Flames, the voltaic arc, electric sparks in various forms and conditions, and vacuum tubes are discussed in succession; and even those conversant with the subject will find a large amount of valuable information, especially as the author includes in the discussion such questions as the temperatures of different sources, and touches on the theory of the electric discharge.

The third chapter, dealing with prisms, has been written by Dr. H. Konen of Bonn. The passage of rays through prisms is traced, and full justice is done to Lord Rayleigh's investigations, though two propositions in §§ 309 and 310, assigned to Wadsworth, are really contained in Rayleigh's first paper. I think that the investigations of this chapter might have been made clearer and shorter by a more frequent application of Fermat's principle. Special attention may be drawn to the reduction of prismatic measurements to wave-lengths by means of the interpolation formulæ, which have been given by Cornu and Hartmann (§§ 327 and 328). Insufficient attention, to which I must plead guilty myself, has been given

in this country to these equations, which are much more convenient than Cauchy's formula, and which much facilitate the reduction of measurements made with prism spectroscopes. The chapter concludes with a complete description of the various devices for compound and direct vision prisms. The combination of prisms to obtain great dispersion and resolving power has lost a great portion of its interest since the more general introduction of diffraction-gratings for spectroscopic purposes. We therefore turn with special interest to the fourth chapter, which deals with diffraction-gratings.

After a short history of the methods of ruling gratings, a discussion of plane gratings is given, which chiefly follows Rowland's and Cornu's investigations. About thirty pages are devoted to concave gratings. A very clear and elegant theory of these gratings, due to Prof. Runge, is, for the first time, published in full, and deserves to be widely read. It includes the very important practical question of the easiest method of adjusting the relative position of the slit, grating and camera, so that when the carriages roll along the beams, the spectrum should remain in focus and be displaced only in a direction parallel to the plane containing the two rectangular rails.

A disadvantage of concave gratings, which has been pointed out by Rowland in his first discussion, is its astigmatism, a point on the slit being drawn out into a line. It seems to me a curious fact that no one should have attempted to correct this astigmatism by means of cylindrical lenses. I was only waiting until the large concave grating of the Owens College was available, to try some experiments in this direction. Prof. Fitzgerald tells me that he has had the same idea, and has already determined by experiment the proper position of the two focal lines of the correcting lens. In looking over the pages of Prof. Kayser's book, I find that I had overlooked a paper by Mr. J. L. Serks, in the *Journal of Astronomy and Astrophysics*, in which the question is, in fact, solved theoretically. It is curious, however, that the author does not seem to have realised this application of his investigation, which he only applied to proving the possibility of finding a position for a comparison prism such that the horizontal edges of the prism should appear sharp on the spectrum plate. If the light coming from a luminous point is passed through a combination of a cylindrical and convex lens, placed so as to give a horizontal focal line in the position given by Serks, and a vertical focal line coincident with the slit, the astigmatism of the concave grating will be corrected.

The fifth chapter discusses the construction of spectroscopes, a good deal of space being devoted to the various devices for securing minimum deviation. The author seems to me to attach a somewhat exaggerated importance to the minimum deviation as regards its necessity to give definition. If the collimator is properly adjusted, and the faces of the prisms are plane, the spectra should be equally perfect whether the prisms are in the position of minimum deviation or not. When many prisms are used it becomes, of course, necessary that each prism should wholly take in the beam of light which has passed through the previous prism, and, in that case, the position of minimum deviation is most convenient. For the usual prism, cut so that its base is equally inclined to the faces, the position of minimum deviation is also that of maximum resolving power; but the prism may be turned considerably out of the symmetrical position without sensibly affecting its power of resolution.

The theory of the spectroscope, including the question of resolving power and purity, is fully discussed; but I venture to think that the treatment of the brightness of spectroscopic images might be made much simpler and clearer, and in some cases more correct, by starting from the following two very simple principles.

It is a well-known proposition, in the formation of images by lenses, that the brightness of the image, as deduced from the laws of geometrical optics, simply depends on the emitting power of the source and on the solid angle of the converging beam forming the final image. When the observations are taken by the eye, and the whole pupil is filled with light, the last solid angle is fixed; hence the brightness cannot be altered by any optical arrangement. The same proposition also holds when the light is refracted through prisms, provided the light is homogeneous. The second proposition, to which I have alluded, states that if the object is linear, the width of the central image, due to the finiteness of the wave-length of light, also depends only on the solid angle of the conical beam forming the last image.

These two propositions enable us to draw all the necessary conclusions without restrictions, such as that made by Kayser as to the position of minimum deviation of the prisms; and the results of § 508, derived from a paper by Wadsworth, will be found to need correction in some important particulars. The latter portions of this chapter deal with Michelson's researches, the applications of fluorescence, phosphorescence, and finally with photographic and bolometric methods.

The last chapter is devoted to spectroscopic measurements.

The value of the book is increased by the fact that the author has not been satisfied with a statement of results, but in many cases has added his own criticisms. I entirely agree with the statement made in the preface, that a mere compilation without critical discussion is of very little value. In the present volume there has not been so much opportunity of touching on tender spots as will arise in subsequent divisions of the subject; but Prof. Kayser's evident fairness and knowledge of his subject render it certain that no one need be afraid of placing himself under the judgment of so competent an authority. While congratulating Prof. Kayser on the successful accomplishment of the first portion of his task, we conclude with the hope that we may soon be able to welcome a second volume. ARTHUR SCHUSTER.

LIFE AND WORK OF C. GERHARDT.

Charles Gerhardt: sa Vie, son Oeuvre, sa Correspondance: 1816–1856. *Document d'Histoire de la Chimie.* Par M. Édouard Grimaux et M. Charles Gerhardt. (Paris: Masson et Cie.)

A BIOGRAPHY which involves the history of the turning-point of a science is always interesting; and this one in particular, which tells the tale of the

struggles of a young Alsatian, who came to Paris against the desire of his father to fight his way to recognition and fame, is almost dramatic in the way in which it enlists the sympathy of the reader. The story loses nothing by being told by the distinguished son of the subject of the memoir, and by the unfortunate Edouard Grimaux, whose recent death was—at least, in part—due to the jealousy of the Government of France when any attack on its action is made by men in its official pay. Indeed, it may be surmised that M. Grimaux found in the recital of Gerhardt's combats with those in power some consolation for his own recent dismission from office.

Charles Gerhardt was born at Strassburg on August 22, 1816; he passed his schooldays at the Gymnasium there, and his father, in order to prepare young Gerhardt for the charge of a white-lead works which had fallen into his hands as the result of an unfortunate speculation, sent him to Carlsruhe, where, from 1831 to 1834, he studied chemistry and allied subjects. But, on his return to Strassburg, he found the monotonous existence of a works-manager far from his taste; and after stormy interviews with his father, at which he declared his intention to devote himself to the pursuit of pure chemistry, he entered the army as a preliminary step. This step, however, was far from leading him to the desired goal; and, deciding to abandon the calling of a soldier as rapidly as he had formed the intention of taking it up, he applied to relatives in Germany, requesting help to buy a substitute. The help was furnished by no less than Liebig, who had heard of his ability from his teacher Erdmann, and thought it worth while to secure a promising assistant by payment of 40*l.*—the necessary sum.

Needless to say, the money was afterwards refunded by his relatives.

It will be gathered from this short sketch of Gerhardt's youth that he was a young man of very decided character, and that he did not always take the surest way of gaining his desires—that, in fact, he had more of the *fortiter in re* than the *suaviter in modo*.

After having studied for two years at Giessen, then rising rapidly into repute as the first school of chemistry, Gerhardt made his way to Paris armed with a letter of introduction to Dumas and with authorisation to translate Liebig's "Organic Chemistry" into French—a task for which his bilingual education eminently suited him. At first all went well. Liebig's introduction opened to him the doors of the chemists of the day; but he failed, in spite of all efforts, to obtain a junior post. His repeated endeavours to secure a place in a laboratory where he could continue his researches were met with the advice—impossible to follow, under the circumstances—"Do some work, and you will find a place." But in order to continue his researches a laboratory was necessary; and this *impasse* barred his way for months. At last Cahours obtained leave from Chevreul for him to occupy a bench in the laboratory of the *Jardin des Plantes*. Here he carried on investigations on hellenine; and, at the same time, he published a note on the constitution of salts of organic acids and their connection with salts of ammonia.

The reader must peruse the memoir itself if he wishes to become acquainted with Gerhardt's struggles—how his too direct expression of his opinions, in words calculated to irritate rather than to gain converts to his views, hindered his progress. Indeed, his relations—afterwards so intimate and so inseparable—with Laurent, began with an encounter. But both soon found that their ideas of the necessity of a reform in chemistry, and of the manner in which it was to be carried out, were nearly identical; and they joined forces in a campaign against the ruling powers. These powers were not mollified by the manner in which the campaign was conducted. Even Liebig, his old master, might be excused for resenting words such as the following, relating to a nitrogenous substance, a derivative of cyanuric acid, to which Liebig had given the name "mellon":—"Ce n'est pas une partie seulment du memoire de M. Liebig qui est fausse, mais toute l'histoire du mellon, toutes ses transformations, toutes ses reactions." Still, that did not excuse Liebig from saying that Gerhardt reminded him of a highwayman, who attacks and robs travellers and, after having stolen their clothes and ornaments, wears them with effrontery in the streets.

These were, however, days of hard hitting; and had the contest been confined only to words, little harm would have been done. But, unfortunately, the positions of instructors in the provinces and at Paris were so badly paid (and it is scarcely improved yet) that many offices were held by one individual, and places which gave command of several laboratories were occupied by those who were disinclined to abandon any one of them. Thus the best paid of the Government offices—that of Director of the Mint—had a salary attached to it of 600*l.* a year; many of the chairs were worth little over 100*l.*; and the emoluments sometimes became the gift of an elder to a younger member of a family, and were dispensed with little regard to scientific fitness or eminence. Moreover, it is the unfortunate custom in France that if a man wants a position he must ask for it—nay, he must personally supplicate those in power to bestow it on him. Thus, a candidate for admission to the Institute must canvass the members, hat in hand, and report has it that the reception accorded to a candidate is not always flattering to his *amour propre*. But we in England have little reason to criticise; for, though admission to the Royal Society's Fellowship is, fortunately, free from such disagreeable incidents, the candidature for a chair, with its system of testimonials and interviews, might well be reformed.

To return to Gerhardt. After several years of disappointment, he was finally appointed (through Dumas' influence) to the chair of chemistry at Montpellier, at one time renowned for its medical school; here he had only 6*l.* a year to spend on apparatus, and 12*l.* to provide specimens! Moreover, he found his colleagues occupying sinecures, and anxious to retain their chairs, as such, by discouraging the attendance of students. It is exceedingly galling to a "new broom" not to be allowed to make a clean sweep; and it is difficult to keep on terms of sufferance—not to speak of friendship—with what may be disrespectfully called the old besoms. So Gerhardt's new chair was by no means a comfortable seat; and after some years he applied for, and obtained, leave of absence on half-pay—another arrangement which sounds strange in our ears. In the meantime, however, he had married Miss Jane Sanders, a Scottish lady, resident with her mother and sister at Montpellier; this union was,

from every point of view, a happy one. During his leave of absence, Gerhardt came to Paris; and again, it is strange to us on the other side of the Channel, many of whom are content with an occasional visit to the capital, to see how absence from Paris is, to a Frenchman, absence from civilisation. "La vie du province"—there is no expression which so fitly renders the *ennui* of banishment from "ce cher Paris." But to live at Paris was not necessarily to find an official position; and, after many disappointed hopes, Gerhardt finally accepted two chairs at Strassburg! "Le cumul," as pluralism is termed, has attractions, it appears, to those to whom it is offered.

Gerhardt was not long at Strassburg, however, before he succumbed to an attack of peritonitis; and, after a few days' illness, during which he regretted nothing more than the cessation of work, he passed away.

Gerhardt shared with other reformers absolute belief in his own theories, and want of patience with conservatives who would not be convinced. Patience and a more gracious manner would have not only given him a happier and more prosperous career, but would also have accelerated the acceptance of his doctrines. Still, it is difficult for us to judge. Suffice it to say that the formulæ which we still use are, for the most part, Gerhardt's. While Gerhardt referred the formulæ of compounds to the volume occupied by the molecular weight in grams contained in 22·4 litres of the gas, Laurent extended the same numerical conception to the "formulæ" of elements; while Gerhardt wrote H_2O for the formula of water, but O for that of oxygen, Laurent introduced Avogadro's and Ampère's view that the molecular formula of oxygen should be O_2. They united their forces in advocating the adoption of "types," such as that of H_2, H_2O, and NH_3; and Williamson supplemented their ideas by the addition of "double types"—substances derived, for example, from two molecules of water by replacement of an atom of hydrogen in each. Later, as every one knows, this conception developed into structural formulæ. But the idea of a homologous series, too, was first introduced by Gerhardt; and it has proved one of the most fertile in the whole domain of organic chemistry.

We have witnessed as great, if not a greater change in chemical theory during recent years. Fortunately, it has not aroused the same passion, although it has been resolutely opposed by a conservative faction. At the meeting of the French Association at Havre, the writer remembers well a discussion of which the central point was whether the formula of barium sulphate should be written $BaO.SO_3$ or $BaSO_4$. Is it possible that, twenty years hence, we shall still find a remnant for whom the ionic theory has no value?

W. R.

MONISM FOR THE MULTITUDE.

The Riddle of the Universe at the Close of the Nineteenth Century. By Ernst Haeckel, Ph.D., M.D., LL.D., Sc.D., and Professor at the University of Jena. Translated by Joseph McCabe. Issued by the Rationalist Press Association, Ltd. Pp. xvi + 398. (London: Watts and Co., 1900.)

THERE is a twofold pathos in this book, for with it the author—whom to know is to love—draws, he says, "a line under his life-work," and with it he once more illustrates the sad fact that a great investigator may not be convincing as a philosopher. The book begins with a reproach that philosophy is ignorant and that science lacks consistency, and we end it with a sigh for the same reasons. As a few readers may remember, Haeckel projected, almost a generation ago, the scheme of a "System of Monistic Philosophy"; but the shadow of age has fallen upon him while his early ambition was still not within sight of being realised. Therefore he has given us in this, "which has something of the character of a sketch-book," only a hint of what might have been. For the non-fulfilment of his dream of youth, the order of things is more responsible than the author, for there are few who have worked harder and, at the same time, more brilliantly for their day and generation.

But although Haeckel speaks of the volume as a sort of sketch-book, this is not meant to suggest that its conclusions are mere *obiter dicta*. On the contrary, as he tells us, he has been meditating for fully half a century on the problems of evolution, and now, in his sixty-sixth year, he gives us "the ripe fruit of his tree of knowledge." If this is not an altogether happy metaphor, it may serve to remind the unsympathetic that we have here, at least, the sincere voice of "a child of the nineteenth century," who is conscious of no dogmatism, though the suggestion of it seems painfully frequent, who blinks no facts so far as he is aware, who is impelled by no motive but a love of truth.

> "My 'Monistic Philosophy' is sincere from beginning to end—it is the complete expression of the conviction that has come to me, after many years of ardent research into Nature and unceasing reflection, as to the true basis of its phenomena."

Impulsive the author certainly is, as he has always been—impulsive, for instance, to champion Darwinism in the early days of its unpopularity, and impulsive in his confidence in genealogical trees which many a Jack has hewn at while the giant climbed—but ignorant no one will venture to call the zoologist who has laid so many solid blocks in the scientific edifice, and to whom the Royal Society has lately awarded its Darwin medal. There is, perhaps, no important idea in this volume, admirably translated by Mr. Joseph McCabe, which is not to be found in that wonderful work of 1866, the "Generelle Morphologie"; but the ideas are now illumined with a wealth and confidence of illustration which only a big personal share in the scientific progress of the last forty years could give.

The book, as we have said, begins with a reproach. Scientific workers "do not see the wood for the trees"; the metaphysicians "trouble not about the individual trees, and are satisfied with the mere picture of the wood"; betwixt the two is the multitude, still oppressed by "the riddle of the painful earth." But this incoherence, this ignorance, this oppression result from that blindness to the open secret of unity which is the lasting defect of Western thought. There is but one fact, and, as a writer in the *Monist* recently remarked, it is an evidence of human frailty that the word ever got a plural; there is but one science, the science of the order of nature; there is but one comprehensive riddle, the problem of substance; and there is but one hopeful attempt at solution, namely, of course, scientific monism.

We cannot here discuss the detailed arguments of the book, but the author's standing requires that we should at least indicate the general trend. The chapters run:—the nature of the problem, our bodily frame, our life, our embryonic development, the history of our species, the nature of the soul, psychic gradations, the embryology of the soul, the phylogeny of the soul, consciousness, the immortality of the soul, the law of substance, the evolution of the world, the unity of nature, God and the world, knowledge and belief, science and Christianity, our monistic religion, our monistic ethics, solution of the world-problems. It is from the last chapter that we select a quotation which sums up the author's position.

"Towering above all the achievements and discoveries of the century, we have the great, comprehensive 'law of substance,' the fundamental law of the constancy of matter and force. The fact that substance is everywhere subject to eternal movement and transformation gives it the character also of the universal law of evolution. As this supreme law has been firmly established, and all others are subordinate to it, we arrive at a conviction of the universal unity of nature and the eternal validity of its laws. From the gloomy *problem* of substance we have evolved the clear *law* of substance. The monism of the cosmos which we establish thereon proclaims the absolute dominion of 'the great eternal iron laws' throughout the universe. It thus shatters, at the same time, the three central dogmas of the dualistic philosophy—the personality of God, the immortality of the soul, and the freedom of the will" (pp. 388–389).

There seems some need here for a criticism of categories, but we make only two remarks.

Since, as Haeckel says, "no scientist ever asks seriously of the 'purpose' of any single phenomenon," since, in other words, science does not discuss the meaning or significance of experience, it is obviously *as a philosopher* that he seeks to demolish the ancient beliefs, and there will no doubt be found those who, while bowing to his scientific authority, will prefer Kant or some other as their philosophical guide.

Secondly, to scientific minds who regard laws of nature as merely conceptual formulæ summing-up certain sequences of experience, it may seem that to replace "a deliberate architect and ruler of the world" by "the eternal iron laws of nature" is to be guilty of an anthropomorphism precisely analogous to those on which the illustrious author pours contempt. Altogether, this endeavour to give monism to the multitude seems to us to bear an unfortunate resemblance to the device of trying to pay debts by means of an overdraft without first facing the question of general solvency.

When we say that we do not find in this volume any solution of any of the riddles of the universe, we mean no particular reproach against the author, for he is a scientific worker, and we do not think that it is within the scope of science to solve "Welträthsel." In other words, we adhere to the position that "all science is description, not explanation." If the phenomena which we label gravitational or evolutionary were once riddles, they remain so, although Newton and Darwin have given us what Karl Pearson calls thought-economising devices for dealing with them.

The book falls short of its high ambition because it is neither scientific enough nor philosophical enough to win conviction. It is not scientific enough, since mere formulæ (endowed with "eternal validity") stalk through the book, doing this and doing that, like the Greek gods come back again, and since when the well-known difficulties raised by the "big lifts" in the great process of Becoming have to be faced, the author has no new light to offer (we are not forgetful of his illumining work in the past), but simply rubs his lamp and summons the two genii, Substance and Evolution, and the work is done. In plain fact, Evolution travels through the book like a creator in disguise. There is many a quaint illustration of the metaphysician unconscious of himself, as when the author, after referring the doctrine of the conservation of matter and energy (his "law of substance" or "fundamental cosmic law") to Lavoisier, Helmholtz and others, says: "In the ultimate analysis it is found to be a necessary consequence of the principle of causality."

Nor does the book seem to us philosophical enough; it does not even show an appreciation of the philosopher's problems. In confessing that we are as far from understanding "the innermost character of nature," "the problem of substance" as Anaximander and Empedocles were 2400 years ago, Haeckel says:—

"We do not know the 'thing-in-itself' that lies behind these knowable phenomena. But why trouble about this enigmatic 'thing-in-itself' when we have no means of investigating it, when we do not even clearly know whether it exists or not."

Now many who agree with this assumption of the futility of the "things-in-itself" may at the same time doubt whether the philosopher troubles himself much about it either, whether this is not mere bluffing in presence of the fact that our "routine of perceptions" *is* a problem (not to be ignored, even if insoluble), whether transcendental formulæ have no utility because scientific formulæ (*e.g.* atomic theories, ether theories, &c.) seem to many minds to have much, and whether the position indicated is consistent with the energy expended throughout the book in "shattering" Christian and other philosophies of life which have obviously no standing if from the outset the problem of the significance and meaning of experience is ruled out of court as an irrelevancy. One feels that the author has not quite learned the "rules of the game" when he is satisfied with saying in answer to idealistic monism:—

"In my opinion the existence of ether is as certain as that of ponderable matter—as certain as my own existence, as I reflect and write on it. As we assure ourselves of the existence of ponderable matter by its mass and weight, by chemical and mechanical experiments, so we prove that of ether by the experiences and experiments of optics and electricity."

But this is just Dr. Johnson and Bishop Berkeley over again, and no idealist will so much as turn a hair.

SCHMEIL'S TEXT-BOOK OF ZOOLOGY.

A Text-book of Zoology; treated from a Biological Standpoint. By Dr. O. Schmeil. Translated by R. Rosenstock, and edited by J. T. Cunningham. Parts ii. and iii. Reptiles to Invertebrates. (London: A. and C. Black, 1900.)

THE first part of this school text-book was noticed in our issue of August 23, 1900, and with the publication of Part iii. the work is completed. Considering

the fulness with which it is illustrated, and the somewhat restricted circulation of treatises devoted to zoological subjects, the work is a marvel of cheapness; and the manner in which it is turned out reflects the greatest credit on the publishers. Allusion has been previously made to the popular and interesting style in which it is written; and as examples of clear and accurate treatment of somewhat difficult subjects we may call attention to the description, in Part ii., of a bird's respiration while on the wing, and the manner in which the flight-feathers present either an impervious barrier or an easily traversed sieve to the air according to the exigencies of flight at the moment. The descriptions of these functions are, indeed, decidedly better than in any other text-book with which we are acquainted; and they are by no means solitary instances, both in the vertebrate and invertebrate parts. Again, the diagram of the circulation of the carp on p. 274 may be cited as an excellent example of clearness. And it may be confidently affirmed that, so far as physiology and habits are concerned, the work is for the most part all that can be desired.

But physiology and the description of the habits of animals, although of the highest importance, by no means constitute the whole of zoology; and whether the subject be treated from a "biological" or from any other standpoint, there can at the present day be no sort of excuse for the numerous omissions and inaccuracies which occur in the systematic portion of Part ii. Even if the author's acquaintance with systematic zoology were insufficient to enable him to recognise these shortcomings, it should have been, as we said before, a part of the editor's task to see that these were remedied in the English translation.

Were we so disposed, we could seize many opportunities of finding fault with the generic and specific nomenclature employed; but we will let such minor matters pass without notice, and content ourselves with calling attention to other points.

Taking first the section on birds, we find that not only is the classification of a decidedly antiquated type, and very different from any of those commonly employed, but that it also contains several errors and inconsistencies. The group "Impennes," for example, was formed in 1811 by Illiger for the penguins, but in the present work (p. 225) we find it typified by the divers, which, together with the grebes, constitute Illiger's "Pygopodes"! Nor is this all, for whereas the "Impennes" are termed "Divers," yet no representative of the divers proper (Colymbidæ) is referred to in the work; the notice of the group commencing with the grebes, which are followed by the auks, and these, again, by the penguins—the typical and sole representatives of the entire order. Take, again, the case of the gulls or "Lariform" birds (page 223). Here we have first an account of the herring-gull, followed, under the head of "allied species," with a brief mention of the black-headed gull and the albatross. Of course, it is justifiable to follow Dumeril in including both the gulls and the albatross in a single group (Longipennes), but the reader should have been informed that, according to the universal usage of British ornithologists, the albatross and the other petrels are separated from the gulls as a distinct order (Tubinares).

To take a third instance, those responsible for the book may, if they please, follow the totally obsolete system of including the so-called American vultures (Cathartidæ) among the Vulturidæ, or true vultures of the Old World. But there is no justification whatever for taking the condor as the sole example of the latter family, and avoiding all mention of a single species that really belongs to it! And here it may be remarked that we think ornithologists would be well advised if they discarded the use of the name "Vultures" for the Cathartidæ, and called them all "Condors." Misprints, we are glad to notice, seem few and far between in this and the other sections of the book, but Alaudictæ, in place of Alaudidæ (p. 181), should have caught the proof-reader's eye.

Passing on to the section on reptiles, we have to deplore the use of an antiquated and discredited classification, the groups Ophidia and Lacertilia being regarded as of equal value with Crocodilia and Chelonia. But even more serious is the total absence of the Rhynchocephalia among the ordinal groups of the Reptilia, its single representative, the New Zealand tuatera, being, so far as we can see, not even mentioned in the book! Surely, even from a "biological standpoint," such a remarkable creature is worthy of some notice in a "zoological text-book!"

Nor are minor points for criticism lacking in this section. For instance, on p. 246, the account of the American alligator is simply ludicrous; while the reader should have been informed that an allied species occurs in China. Again, had the editor taken the trouble to refer to the British Museum "Catalogue of Chelonians," he would have found that there is no justification for the use of the name "Chersidæ" for the land tortoises (p. 250), and also that in place of *Testudo indica* being the proper title for the "giant tortoises" of the Galapagos Islands, that name denotes an extinct species from the Mauritius.[1]

Omitting mention of the Amphibians (not because there is no room for criticism), a few remarks are called for in the section devoted to fishes. Here the up-to-date zoologist can scarcely fail to be surprised to find the group divided into (1) bony fishes, (2) enamel-scaled fishes, (3) sharks and rays, (4) round-mouthed fishes, and (5) lancelets, without the slightest indication as to differences in the value of such divisions. To those who have kept themselves at all abreast of modern zoological research, it is almost inconceivable that such a classification should be presented to students.

As regards the details of the class in question, it is decidedly strange to find the "enamel-scaled" group exemplified by the sturgeons, while the two living types (bony pike and bichir) which alone retain scales of this description are totally ignored; and surely the unique type of limb-structure presented by the latter alone among modern fishes should have itself entitled the creature to special mention. Even more startling is the omission of any reference to the lung-fishes (Dipnoi), which we presume the author would include in the "enamel-scaled" group, although the student is left entirely in the dark on this important point.

Without in any way wishing to be unduly severe, we

[1] Neither the popular nor scientific name of this reptile occurs in the index.

can scarcely refrain from saying that in the second part of the work the author seems to have gone out of his way to ignore some of the most peculiar, and therefore the most instructive, types of reptile and fish life.

As regards Part iii., which deals with invertebrates, we feel ourselves less qualified to speak authoritatively either in respect to the excellence of treatment or the reverse on the part of the author, and therefore refrain from detailed criticism. So far, however, as we can judge, the classification adopted is, in some respects, less open to objection than is that of the vertebrates. Even here, however, the author gives opportunity for criticism in many places. For example, among the molluscs no mention is made of Dentalium, which most modern zoologists regard as the representative of an order by itself. And it is scarcely consonant with the facts to say (p. 445) that Ammonites "were animals similar to the nautilus in all essentials of form and structure," unless, indeed, the author attaches a very different meaning to the word "essential" than we are disposed to assign to it. But the most astounding feature in the whole book is the total omission of the Brachiopods, the Tunicates, and the Polyzoans!

At the end of the work two pages are devoted to geographical distribution. Here it will surprise many zoologists to find the domesticated zebu given as one of the characteristic animals of the Indian region, and "the antelope" as one of those of Africa. Neither is it apparent why the leopard *and the panther* are included among the characteristic mammals of Africa as distinct from India. Again, the statement (p. 485) that "tracts of land (*e.g.* the Sahara) have been elevated out of the ocean" may be cited as an extremely unfortunate one, having regard to modern views as to the origin of deserts.

If the editor in his preface is justified in his statement that "the book is far superior in many respects to any other elementary text-book of the subject known to me," we may be permitted to add that in other respects it is decidedly inferior to several works of the like nature that could be named. R. L.

OUR BOOK SHELF.

The Mycetozoa and some Questions which they Suggest. By the Right Hon. Sir Edward Fry, D.C.L., LL.D., F.R.S., F.L.S., and Agnes Fry. Pp. viii + 82. (London: *Knowledge* Office, 1899.)

"WHAT'S in a name?" Much, when it bars the way to the knowledge of a group so rich in curious and beautiful forms, and so important in the information that it can afford upon the nature of protoplasm. The want of a familiar name has led the authors to employ "myxies," and the word may find acceptance, as it is not hard to pronounce or remember, while it has the advantage of leaving open the question of what their pets are. Though generally reckoned now among plants, they are so different from even the nearest groups that they may well receive a neutral name.

They have formed the subject of very excellent monographs in various languages, and to these the student must turn who wishes to investigate the Mycetozoa thoroughly. But the very excellence of these monographs renders them unsuitable to those that wish only such a general outline as will place the group in true perspective in its relation to other low forms of living beings, and will indicate its value in the study of living protoplasm in simple organisms. There was room for a small book that would give such an outline, and this little work has been written to do so. One cannot read it without recognising that it is the work of enthusiasts whose aim is to communicate to others the pleasure gained by themselves in the study. But no less evident is the clearness of statement of the points of chief interest resulting from width of view and facility of expression. One can recognise that it is the work of amateurs by occasional slips, as on p. 35, where it is stated that all plants with a square stem and lipped flowers belong to the family of the Labiatæ. But such slips are few, and no one can read the book without interest, while those not already familiar with the Mycetozoa will have gained as clear a conception of their nature and scientific interest as can be acquired without actual personal study of these organisms. The descriptions are supplemented by figures admirably selected and executed. The book is one that should induce those who read it to desire a fuller knowledge and to become students themselves. It will be found an excellent introduction to the study of a most interesting group.

A School Chemistry. By Dr. John Waddell. Pp. xiii + 278. (New York: The Macmillan Co., 1900.)

MANY text-books of physics and chemistry are now constructed upon the interrogatory plan. Judiciously used, the method has real educational advantages, for it makes the student think for himself instead of merely using his brain as an absorbing medium for what he reads or is told. But the Socratic principle is often overdone. The questions which a teacher asks—either in book or verbally—in connection with experiments in progress, are frequently not those which present themselves to the mind of the student. True, by suggesting questions the pupil can be led to see the main points to be brought out, and to have an interest in finding answers to them; but the ideal plan is to let his own mind do the questioning instead of the mind of the teacher. While, therefore, we agree that the interrogative method largely employed by Dr. Waddell is often stimulating, and certainly much better than the plan of former text-books for schools, we do not believe it is altogether satisfactory.

Consider a boy in a laboratory, with Dr. Waddell's book open at Experiments 9 and 10 (Chap. ii.). The experiments are on the decomposition of water by potassium and sodium, and will often result in accidents unless performed under the eye of the teacher. But leaving this out of account, let us see the questions asked in the course of the description of Experiment 10; they are as follows: "Does the potassium sink in the water, or does it float? What colour has the flame? . . . What shape does the sodium assume? Note how far it acts like potassium, and how far it differs. Is there a flame? Try the experiment with *hot* water. . . . Why is there a flame in some cases with the sodium and not with others? What is the colour of the flame? Does sodium or potassium act the more violently on water?" Now a question we would ask is: How is the pupil to give his answers? Is he supposed to write a reply to each interrogation, or merely to make a mental note of it? If the former, then the pupil must soon get weary of the obstacles offered to the progress of his practical work by the everlasting questions prompted, not by his own curiosity, but by a book. In fact, we do not believe it is possible to carry out the Socratic method of science instruction successfully by means of a text-book. The spirit of inquiry must come from within, or be inspired by a teacher watching the progress of an experiment.

It must not, however, be concluded from the foregoing that Dr. Waddell's book is destitute of the elements of

success. He does not use the plan of questioning to the excess characteristic of some other authors of recent text-books of chemistry; and his book has some special features which make it worth adoption in elementary classes in schools and colleges. The intelligent order in which the subjects are dealt with, and the attention given to industrial processes, are particularly worthy of credit.

Die Photographie im Dienste der Himmelskunde. Von Dr. Karl Kostersitz. Pp. 53. (Wien: Carl Gerold's Sohn, 1900.)

THIS short monograph is a reprint of a lecture given by Dr. Kostersitz before the Vienna Photographic Society. The author describes in a somewhat general way the results that have been obtained by applying the camera to the end of a telescope and turning it towards the heavens. We are thus introduced to the appearance of the general features of the sun in and out of an eclipse, and a brief reference to the planets and asteroids as shown us by photography. Meteor photography is more fully described, and the author here gives two illustrations showing trails as photographed by him. The method of determining the relative brightness of stars by photographing them slightly out of focus is described, and a few words are written about the photography of the Milky Way. The illustrations, which are numerous and good, are chiefly from Scheiner's "Photographie der Gestirne," there being two excellent heliogravures showing the nebula of Orion and Barnard's Milky Way.

The last portion of the book is devoted to the publication of twelve replies that were received from different authorities in answer to a suggestion, proposed by the author, of erecting an observatory on the top of the "Schneeberg." These form interesting reading, although they hardly have any connection with the subject-matter of the book itself.

Although the monograph does not pretend to be complete, yet it gives the reader an idea of the important part played by photography in astronomy.

Die Säkular-Verlegung der Magnetischen Axe der Erde. Von W. van Bemmelen. (Observations made at the Royal Magnetical and Meteorological Observatory at Batavia.) Vol. xxii. Appendix i. Pp. 30.

THIS is an attempt to trace the position of the earth's magnetic axis during the last three centuries, on the supposition that a knowledge of magnetic declination is sufficient to determine the direction of its axis. Great circles drawn through different points, and coincident at these points with the magnetic meridians, would intersect in the poles of the magnetic axis, if the earth were a uniformly magnetised sphere. As this is not the case, the circles all pass through an arctic and an antarctic region instead of through two points, and Mr. van Bemmelen calculates by the method of least squares the point in each region which is nearest to the circles. The two points thus found he takes for the intersections of the magnetic axis with the earth's surface. The reader must be referred to the original for the clever manner in which the calculations are simplified and carried out. The method is first tested for the year 1885, when it is found that the magnetic axis, calculated in this fashion, agrees closely with that derived from the more rigorous analysis of Neumayer and Ad. Schmidt. It is then applied to the declination values for the years 1600, 1650, 1750, 1770 and 1842, and the author draws from the results thus obtained the conclusion that the magnetic axis does not revolve round the geographical axis, but that there seems to be a tendency to revolve round Nordenskjöld's aurora pole. A doubt must necessarily arise in the mind of the reader as to how far the older observations are sufficiently numerous and correct to allow any certain conclusions to be drawn from them. Any one looking at Neumayer's Atlas (Berghaus) of Terrestrial Magnetism will be struck at once by the fact that the distribution of magnetic declination in the year 1600 is represented as being widely different from that of a uniformly magnetised sphere. We must conclude that either the observations were not sufficiently accurate to give us a correct picture, or that the earth differed much more from a uniformly magnetised sphere at that time than it does now. As v. Bemmelen has only tested his method at a time when the deviations from uniformity were small, there is considerable doubt whether equally good results would be obtained with irregular magnetisation. The work, meritorious and interesting as it is, cannot, therefore, be said to have led to any conclusion which can be accepted without further evidence.

The Theory of Commutation. By C. C. Hawkins. Pp. 81. (London: J. Tucker, no date.) Price 2*s.* 6*d.*

IN this pamphlet Mr. Hawkins enters into a complete mathematical investigation of the reactions occurring during the process of commutation in continuous current dynamos. The author first examines the case in which the contact resistance of the brushes is neglected, and then proceeds to give a complete solution of the equation for the current in the short-circuited coil, taking into account this resistance. This solution is due to Prof. Arnold and Dr. G. Mie, but our thanks are due to Mr. Hawkins for introducing it into England and for pointing out its practical bearings. Mr. Hawkins shows that the contact resistance is of the greatest importance in preventing sparking; the employment of carbon as the material of the brushes is consequently desirable, since the contact resistance of carbon is about fifteen times that of copper. Allowing for the fact that the surface needed to collect the same current must be about five times as great with carbon as with copper, the carbon brushes are still, approximately, three times as good as copper. The author also points out the other considerations affecting sparking, and goes fully into the question how it may be best avoided, both in dynamos and motors. The mathematical investigation is made clearer by the application of the results to a practical case, and by a careful explanation of the physical interpretation of the equations.

Album of Papúa. Types II. North New Guinea, Bismarck Archipelago, German Salomon Islands. By Dr. A. B. Meyer and R. Parkinson. About 550 figures on 53 plates in heliotype. (Dresden: Stengel and Co., 1900.) Price 50*s.*

THROUGH the energy and skill of Mr. Parkinson, Dr. Meyer has been enabled to publish a second album of photographs illustrating Melanesian ethnology. The present album supplements the first one, which was published in 1894, and is now out of print. The photographs are well taken, and give us instructive glimpses of native life. The short explanation of each plate is printed in German and English, and these little accounts frequently contain notes of great interest, and there are helpful references to previous publications. There is a photograph (pl. xxiii. 2) of a girl playing the "pangolo." In his admirable memoir on "The Natural History of the Musical Bow," Mr. H. Balfour gives an account of the playing of this interesting musical instrument, which differs from that described by Meyer and Parkinson, the original account of the pangolo, by Dr. O. Finsch, being insufficient. Mr. Balfour evidently read into Finsch's figure more than it was intended to convey.

Albums such as these are of very great service to students at home, as good illustrations are much more readily grasped than are long verbal descriptions, and we hope that other albums will follow in due course. This is not the first time that Mr. Parkinson's labours in ethnology have been recognised in NATURE, and we only wish that some of our British residents and traders

in Oceania and elsewhere would follow the good example of this indefatigable and public-spirited German trader.

The Story of Thought and Feeling. By F. Ryland. Pp. 219. (London: George Newnes, Ltd., 1900.) Price 1*s*.

PSYCHOLOGY is not for those who require spoon-feeding. Many, however, nowadays need a rallying-point for allusions in current literature to a fashionable science, and some would fain still perturbations aroused by the self-consciousness of their children's teachers. To such Mr. Ryland offers a little book which is clear and concrete, and as condensed as possible without loss of these qualities. He confines himself to an interesting account of certain mental phenomena, aims rather at description than explanation which can be controverted, and his book is excellent of its kind. Mr. Ryland is familiar with the most modern authorities, and presents a fascinating subject-matter attractively. Mental imagery is most successfully treated. Mr. Ryland employs the selectiveness of attention inadmissibly as an argument against any form of materialistic theory (p. 22), and he is too vague on the relation of will, self, and kindred formulæ; but his story is so far a story that it in general steers clear of controversies the solution of which lies beyond its scope. It can be confidently recommended to the public for which it caters. H. W. B.

A Primer of Astronomy. By Sir Robert Ball, LL.D., F.R.S. Pp. viii + 183. (Cambridge University Press, 1900.) Price 1*s*. 6*d*. net.

WHILE in many respects this little book seems likely to provide a useful introduction to the study of astronomy, it is to be regretted that greater assistance is not given to those desirous of observing the heavens for themselves. Even without the aid of a telescope the beginner may easily make observations, more particularly of apparent motions, which will go far to encourage a real interest in the subject.

A wide range of subjects is touched upon, and most of the explanations are clear and concise. Many of the descriptive parts are also excellent. Some of the more elementary phenomena, however, as the phases of the moon, receive very scant treatment, and the principal astronomical instruments are neither illustrated nor adequately described. Eleven beautiful plates, mostly from well-known photographs, form the most notable feature of the book.

Hand in Hand with Dame Nature. By W. V. Burgess. Pp. x + 240. (Manchester: Sherratt and Hughes, 1900.)

RURAL life and scenes contemplated in an expansive frame of mind provide excuses for the publication of many pretty books. This one does not differ essentially from many others fashioned on the same model. A country scene, a general knowledge of natural history, an impressionable nature, and a certain facility in the expression of poetic sentiment, seem the chief qualifications of the contributors to literature of this kind. A preface is followed by a "prelude," a dog is "a canine friend," and its runs are "peregrinations." We also read of "larks singing in the meridian blue," the brook "which whilom rippled its pure waters over a bed of cleanest sand," "the realm of spiritual immutabilities," "the obyte of summer," and other fanciful matters. The book is not without some attractive and instructive notes on animate nature, but they are almost lost in a maze of platitudes and inconsequent remarks. The statement on p. 39 that grains of corn "have been found in Egyptian mummy-cases, from which marvellously prolific stems have been raised in this country" contains a popular belief as to the growth of mummy-wheat which has been shown over and over again to have no scientific foundation.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Eclipse Photography.

IN a previous letter (vol. lxii. p. 246) the writer called attention to the possible advantage of positive or reversed photography and development in the light in its application to eclipse work. Since that time very considerable improvement has been made in the methods, and it is now easy to develop, in direct sunlight, plates which have been somewhat over exposed. The pictures obtained in this way are as clear and sharp as any that can be obtained in the dark room by ordinary methods. But I have not been able to secure details on such plates that cannot be secured on a negative by ordinary means. In addition, the over-exposure needed in order to obtain a fine picture is not yet small enough to warrant the usefulness of reverse photography in eclipses.

In the measurement of the actinic values which are required to yield various results on the photographic plate, a discovery has been made which will be of value in the development of eclipse photographs. It has been found that a plate which has been over-exposed as much as two thousand times can be developed as a clear, sharp negative in the dark room. This can be done by the addition of four or five drops of saturated hypo solution to a two-ounce bath of hydrochinone developer. A half ounce of Cramer's mixed hydrochinone bath with an ounce and a half of water and five drops of the hypo solution in place of the potassium bromide, gives clear and brilliant negatives, but they are slow in developing. They can probably be developed more quickly by making the bath more strongly alkaline. With a normal exposure, the addition of two drops of hypo enormously retards the development. The plate may look perfectly clean for half an hour or more, but the picture will surely appear by giving it time and keeping the bath in absolute darkness. It may require an hour and a half or more to secure complete development. With experience, which may easily be obtained in the use of the hypo-developer, there is no need that any valuable photographic plate should ever be lost by over-exposure if a proper exposure has been attempted. If the plate cannot be replaced, and loss from over-exposure is possible, a trace of hypo should always be used at the start in the developer.

With the hypo developer it is possible to develop on a Cramer "Crown" plate, either in the dark room or in the light room, any exposure not in excess of one million candle-meter-seconds. The highest limit of exposure for the development of good negatives in the dark room is one which permits the development of positives in the light. A plate two thousand times over-exposed may be developed either as a positive or as a negative. FRANCIS E. NIPHER.

St. Louis, Mo., January 12.

P.S.—This communication has been made somewhat prematurely, in order to direct the attention of those who will take part in the work of the next eclipse to a matter which may have great importance. It may be that the over-exposures with which I have been dealing are less than has been stated. It is, perhaps, open to question whether a fast plate under a thin positive, and exposed in a printing frame for three-and-a-half minutes at one meter from a three-hundred-candle incandescent lamp, is two thousand times over-exposed. There is, however, no difficulty in developing such a plate as a negative.

The Jamaican Species of Peripatus.

Peripatus jamaicensis, Grabh. and Ckll., was described in NATURE, vol. xlvi. p. 514. At that time it was supposed that all the Jamaican specimens represented a single variable species, but the differences observed were considerable, so that the writer (*Zool. Anz.*, xvi. 341) later separated two "mutations," named *gossei* and *swainsonae*. M. E. L. Bouvier has of late years been making admirable studies of Peripatus and its allies, and having procured from London and Cambridge the original Jamaican specimens, he finds that there are in reality two species represented (*Q. Journ. Micr. Science*, xliii. 755). These he classifies as follows:—

(1) *Peripatus jamaicensis*, Gr. and Ckll.
 (*a*) mut. *swainsonae*, Ckll.
 (*b*) mut. *gossei*, Ckll.
(2) *Peripatus juliformis*, Guild., var. n. *gossei*, Bouvier.

Unfortunately, however, the type-specimen of mut. *swainsonae* had twenty-nine pairs of legs, and was *P. juliformis gossei*. This specimen M. Bouvier so identifies, but he overlooks the fact that it is the type of *swainsonae*, and must therefore bear that name. The dark variety of *P. jamaicensis*, which M. Bouvier calls mut. *swainsonae*, may be termed mut. *bouvieri*, and the proper classification will be as follows:—

(1) *Peripatus jamaicensis*, Gr. and Ckll.
 (*a*) mut. *gossei*, Ckll.
 (*b*) mut. *bouvieri*, Ckll. (*swainsonae*, Bouv.).
(2) *Peripatus juliformis*, Guild., var. *swainsonae*, Ckll. (*gossei*, Bouv.)

T. D. A. COCKERELL.

East Las Vegas, New Mexico, U.S.A., January 4.

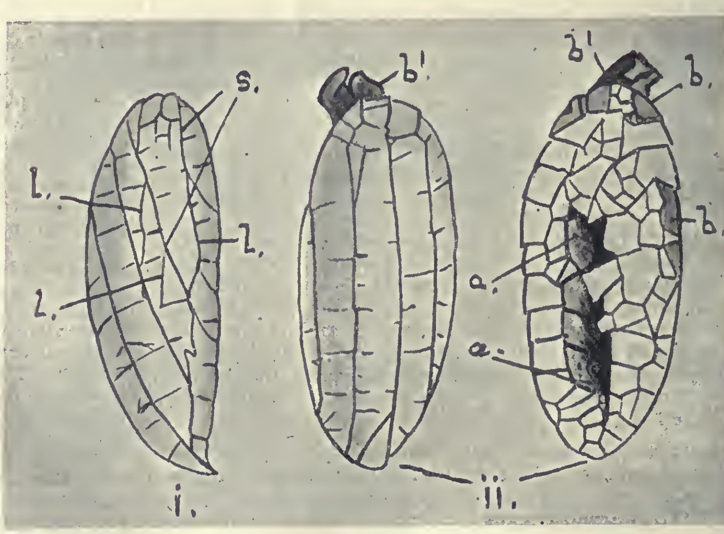
DASYPELTIS AND THE EGESTED EGG-SHELL.

A CHARMING FACT IN NATURAL HISTORY.

ANXIOUS that my pupils should see things about which they hear in the course of their class-work, I have recently lodged with the Zoological Society a standing order for an assortment of "quids," which, mostly of the nature of non-assimilable food, with occasionally a gizzard lining, are thrown out at the mouth by certain birds, snakes, and other creatures, in conformance with a habit extending to the anthropoid apes, since even the famous Chimpanzee "Sally" had acquired it (*P.Z.S.*, 1885, p. 674)—a habit most marked in certain whales, which will thus egest the whole skin of an animal devoured and flayed before being digested.

Among the first set of "castings" which I received were the two pigeons' egg-shells herein delineated, which were "thrown" by the egg-eating snake *Dasypeltis scabra* during the spring of 1900. This animal, confined to tropical Africa, shares with the Indian *Elachistodon* the unique feature of possessing vertebral "teeth," recently proved by Kathariner (*Zool. Jahrb.* Bd. xi. Anat. p. 501) to be, in the African species, true hypapophyses, toothlike but destitute of enamel, which mostly project towards or into the œsophageal lumen, through its median dorsal wall. The two snakes are members of distinct sub-families, and, in their isolation and independent occurrence, they furnish an ideal example of the principle of "convergence," by the process termed by St. Hiliare for Dasypeltis itself the "balancement" and now better known as the "substitution" of organs, as is proved for this snake by Kathariner's assertion that the reduction of its true teeth is effected during ontogeny. *Elachistodon* is unfortunately known only from two examples, and although it occurs in the Bengal area, it is unrepresented in our national collections.

Kathariner, in Dasypeltis, describes hypapophyses for each of the first thirty-four vertebræ, and of these the first twenty-six are much swollen basally, their minute pointed extremities lying each within a surrounding œsophageal lip, in such a manner as to suggest that they come into action only under pressure. The remaining eight are elongated, and with the exception of the last are converted into cutting organs, which perforate the œsophageal roof when at rest. The feeding habits of this animal have been described by Miss Durham in the *P.Z.S.*, 1896, p. 715, and she states that egestion of the shell occurs on the average one and three-quarter hours after the first seizure of the egg. No observations have hitherto been published on the egg-shell as disgorged, and unexpected interest attaches to this, from the fact that the two shells herein described differ to a marked extent in the evidence they furnish of the nature of the processes at work. Both agree only in the presence of a deep indentation (Fig. ii. *a*—*a*). As examined in the dried shell this gives the impression of a definite rent, through which the egg-contents would appear to have been discharged; but as its precise nature cannot be decided without maceration, which would lead to a sacrifice of one of the shells, I leave the settlement of this to the future. Whether it be a cut or a mere depression, it is beyond doubt due to the action of the perforating hypapophyses; for while it is limited to what would appear to be the area of apposition between these and the convex shell surface when in contact, its edges may be inrolled as under pressure from without; and the main reason I have for doubt is that in the larger egg (Fig. ii.) the shell-membrane (*b′*), ragged and torn, projects freely from the upper end, as though the discharge of its contents had been there effected. The shell-area surrounding the afore-named indentation (Fig. ii.) is in each case flattened and somewhat irregularly broken up, the whole presenting



Rough outline drawings of pigeon's egg-shells orally egested by the egg-eating snake, *Dasypeltis scabra*, to show fracture lines and limits of the incision for apparent discharge of the contents. *a*, incision; *b*, areas from which shell-fragments have been removed; *b′*, ruptured shell-membrane; *l*, longitudinal fracture lines; *s*, spiral fracture lines; *i*, non-flattened surface × 1½; *ii*, flattened and non-flattened surfaces of a second shell × 1½.

an appearance unquestionably due to pressure, but whether by contact with the anterior or posterior set of hypapophyses, it cannot at present be proved.

It is concerning the non-flattened shell-area that the conditions are most novel and interesting, for this, though brittle and subjected to a crushing action, is not, as would be imagined, irregularly broken up. The lines of fracture, in places irregular, are for the most part uniformly recurrent and equidistant. In the shell first examined they were found (*s*, Fig. i.) to be mostly longitudinally spiral and broken up in the intervening areas by cross-lines either transversely spiral or feebly transverse; and in consideration of the fact that the pigeon's egg is spirally rotated during its descent of the oviduct and as its shell is superadded, the conclusion suggests itself that the lines of fracture might be those

of a structural differentiation of the shell-substance, rendered pliable by a possible digestive action of the snake's œsophagus or buccal glands. This idea, however, is at variance with the fact that for the second shell (Fig. ii.) the chief lines are longitudinal, and the lesser, so far as they can be recognised, transverse. Of the whole series of lines, the longitudinal and longitudinally spiral are much the more marked, the lesser of the transverse series being much feebler and often incomplete—so much so that they mostly present the appearance of mere superficial scratches, visible only in certain lights, which, by thinning the shell, facilitate its distortion without breakage under pressure. Over the flattened area, however, they become actual "cracks," breaking clean through.

The question thus arises whether the main lines of fracture, if predetermined by shell-structure, may not involve the bird's oviducal wall, or whether the whole result may not be the work of the hypapophyses, under a co-ordinated muscular action of the snake's œsophagus, and it becomes necessary to inquire whether the rotation within both this and the pigeon's oviduct may not be a variable process, especially when it is found that in the shell of Fig. i., which is spirally fractured, there are three longitudinal lines recognisable (*l.*) though of variable extent.

The most conspicuous feature of the main fracture-lines is their regular recurrence and intersection at right angles—*i.e.* they are essentially cancellous. The regular recurrence of the hypapophyses suggest an obvious association with them, but this can only be determined on the death of the snake. If, as seems most likely, the distances between these and the fracture-lines will be found identical, there will remain no question as to how the latter arise. Spiral rotation of the egg beneath the anterior hypapophyses might well produce, under pressure, the spiral and transverse lines of both Figs. i. and ii. Kathariner's description of the condition of the parts, which gives us for each an elastic pad with a central stiletto, are just such as would be required to produce the result observed; and if this be due to the action of the anterior hypapophyses alone, the presence of the lines over the flattened area will be explained, by their being formed before the cutting "teeth" are brought into action.

The regularity of the fractures would seem to favour this view, and if it be correct, one can only marvel at the exquisite delicacy of the muscular apparatus concerned and its co-ordinate activity; but there still remains a difficulty in the case of the longitudinal lines, as it is hardly conceivable that the snake's œsophagus, distensible though it is, could accommodate so large an egg transversely placed.

The slight extent to which, where most fully fragmented, pieces of the shell may break away (as at *b*, Fig. ii.), is a striking feature, and it becomes the more interesting by Kathariner's discovery that the head of the intestine is so modified that it would oppose their passage should they reach it. Both the main longitudinal and spiral lines, as has been said, can be traced into the flattened shell-area, despite the fragmentation of that, and this would seem to justify the belief that the expulsion of the shell-contents must be a slow process, an inverted peristalsis, taking place during the egestive act.

The whole matter bristles with interest and suggestiveness. Thanks to Dr. P. L. Sclater, I am assured the shells which may yet be cast up by the snake now living in the Zoological Gardens, and the carcass of the animal when dead, for the further study of detail. I cannot, however, refrain from bringing to the notice of the scientific public a topic so fascinating as that herein dealt with, since it is one of those exquisite things which only organic nature reveals, and that but rarely.

G. B. HOWES.

THE LIVERPOOL MUSEUM AND PROGRESS.

OUR attention has been directed to a correspondence now taking place in the Liverpool press, *à propos* of a recent meeting of the Biological Society, at which questions were raised as to the disposal of space in the newly-erected extension of the city Museum and the rearrangement of the collections which must thereby ensue. The subject was introduced by Mr. Isaac Thompson, a past president, and continued at length by Prof. Herdman, in his capacity as the founder and leader of the Liverpool Biological School; and the undisguised theme was a protest against the non-communicativeness of the Museum Director and his committee of management, as to their intentions for the future development of their work. These gentlemen, it appears, who, with the sole exception of the Director himself, are in no way scientific, do not choose to consult Prof. Herdman and his co-workers, by whose long years of devoted labour the Liverpool School of Biologists have come to occupy a foremost position among the schools of the United Kingdom, more especially in matters pertaining to the fisheries and of economic importance. The claim which the local scientific men now raise is that their body shall be adequately represented on the Museum Board, and that immediate provision shall be made by this Board for the establishment of collections bearing on the nature and progress of oceanographic research and the fisheries, as more particularly representing the Liverpool area, regarded as a centre of local activity. And they also desire the display of objects of local interest, which shall in some measure reflect the latest advances in our knowledge of nature's operations.

The movement has been immediately taken up by the Liverpool geologists, who have also held a meeting of protest; and the general concern on the part of the combined Liverpool natural history societies is, as to whether the *régime* of the past, under which the Museum, controlled by persons mostly destitute of knowledge and experience of scientific affairs, shall remain a general emporium, having for its object the vain endeavour to fulfil the functions of a great central national museum, or whether it shall be made the centre of accumulation and display of all natural objects of local interest, supplemented only by such others as shall mark, in more especially its philosophic and educational aspects, the groundwork and recent progress in the natural history sciences. General collections from afar and costly *rarissimae* will be forthcoming so long as the exploring Liverpudlian and the enthusiastic amateur exist, while the Directorate cannot be denied the power of purchasing such things, within reason, when so minded. It is with the work-a-day aspect of the Museum, as a rate-supported institution, that advancement is now desired, and most assuredly the latter of the afore-mentioned courses is, for this, the right one, as it is that dictated by general progress in all that pertains to museum work throughout the country, and by common sense. And if this be so, the members of the Liverpool Biological Society, the older and more experienced of whom, under Prof. Herdman's guidance, have become universally recognised experts, having by their labours earned, as loyal citizens, a right of control, constitute a very suitable and competent body of men available for consultation, in itself the first necessary step for the proper strengthening of the Director's hands, if he is to be free and efficient as chief administrator.

Z. T. GRAMME.

M. ZÉNOBE THÉOPHILE GRAMME, who died last week at the age of seventy-four, was one of the pioneers of electrical engineering. He was born in Belgium in 1826, and was brought up as a carpenter; a taste for mechanics led him to attend some scientific

lectures at Liège, and subsequently he came to Paris and entered the "Alliance" factory as a workman. At this factory were built dynamos and arc lamps for lighthouse purposes, and here, as well as at the workshops of Ruhmkorff, where he also worked, Gramme managed to obtain a mastery of the principles of electric currents. The development of the dynamo, although it proceeded rapidly after the discovery of magneto-electric induction by Faraday, had not at that time attained a sufficiently high degree of perfection to give the machine then made any great industrial importance. In 1870, a few years after the discovery of self-excitation by Wilde, Gramme invented the ring armature which has since borne his name. This type of armature had been practically invented before by Pacinotti, a student at Pisa University; but Pacinotti's invention was before its time, and failed in consequence to obtain the recognition it deserved. It was reserved for Gramme, in re-inventing the ring armature, to produce a dynamo which rapidly obtained great commercial importance.

An interesting fact in connection with Gramme's armature is that the English patent was quite inadequate for so important an invention. The reason of this was that at the time the final specification was drawn up Paris was besieged, and Gramme's English agents were unable to obtain all the information they required. Gramme's machine was self-exciting, and combined good commutation with good lamination of the armature core. Also it is noteworthy that, at a time when the principles of the magnetic circuit were not understood, and when it was consequently impossible to design a dynamo mathematically, Gramme's machine had a fairly well proportioned magnetic circuit. Gramme had, without doubt, the engineering mind which is able to feel instinctively whether a machine is well designed or not. Gramme's machines were conspicuous at the Exhibition at Vienna in 1873, at Philadelphia in 1876, and at Paris in 1878 and 1881, and probably owe their success as much to the energy with which they were introduced to the world as to their great intrinsic merits.

Gramme was an Officer of the Legion of Honour and a Chevalier of the Order of the Iron Crown of Austria. In 1897 he was made a Knight Commander of the Order of Leopold, and a banquet was given in his honour at Brussels to celebrate the occasion. He died at his home, near Paris, on January 20, and was buried in the cemetery of Père Lachaise on January 23.

NOTES.

IN consequence of the lamented death of Her Majesty the Queen, and as a sign of mourning, all the meetings of scientific societies announced for the latter half of last week and the whole of this week have been postponed.

THE Amsterdam Genootschap ter Bevordering van Natuur-, Genees- en Heelkunde has awarded the Swammerdam gold medal for 1900 to Prof. Dr. C. Gegenbaur, of Heidelberg. This medal was instituted by the Genootschap in 1880, to be awarded every ten years to the person who in those years made important researches in the sciences cultivated by Swammerdam. It was awarded for the first time, in 1880, to Prof. Dr. C. Th. von Siebold; and the second time, in 1890, to Prof. Dr. Ernst Haeckel.

WE have with deep regret to record the death of Dr. Walter Myers, which took place on January 20 at Pará from yellow fever. It will be remembered that Drs. Durham and Myers went out last June for the Liverpool School of Tropical Medicine to study yellow fever. Both these gentlemen fell victims to their devotion to science, and the latter unfortunately lost his life. The world can ill afford to lose a man of Dr. Myers' stamp, for not only did he show great promise as a scientific worker, but he had the courage and singleness of purpose to go out in the cause of science and humanity to study a very infectious and fatal disease. Many have courage to face bullets in a moment of excitement, but not all have the nobler courage to face an insidious disease with the coolness and nerve necessary for scientific inquiry.

Science announces that Dr. H. C. Bumpus, professor of comparative anatomy at Brown University, and director of the biological laboratory of the U.S. Fish Commission at Woods Holl, has been appointed curator of invertebrate zoology and assistant to the president in the American Museum of Natural History, New York City. The office of assistant to the president, Mr. Morris K. Jesup, is an important executive position, as the Museum has no scientific director. It was created last year and was filled by Prof. H. F. Osborn, who has resigned in order to devote himself more exclusively to research in vertebrate palæontology. A further reorganisation of the staff of the Museum has been made. A department of mineralogy has been formed, with Dr. L. P. Gratacap as curator, while Mr. R. P. Whitfield remains curator of geology, with Dr. E. O. Hovey as associate curator. Prof. Franz Boas and Dr. Marshall H. Saville have been made curators, the former of ethnology and the latter of Mexican and Central American archæology, though Prof. F. W. Putnam retains the head curatorship in the department of anthropology. In the department of mammalogy and ornithology, Mr. Frank M. Chapman has been made associate curator.

A DISCUSSION on the occurrence and detection of arsenic in manufactured products has been arranged for the next meeting of the Society of Chemical Industry, to be held on February 18.

THE Anatomical Society has undertaken to supply the slips requisite for indexing the literature in human anatomy published in Great Britain and Ireland for the International Catalogue of Scientific Literature, which has been set on foot under the auspices of the Royal Society. For this purpose a committee has been appointed, consisting of Prof. Thane, Dr. Arthur Robinson, and the secretary of the Society (Dr. A. Keith).

AT the recent conference of German biologists, held at Berlin, says the *Athenaeum*, a resolution was passed calling the attention of the Imperial Government to the importance of establishing five floating stations on the Rhine for the purpose of biological investigation. Great stress was laid on the practical advantages which pisciculture would derive from these establishments, and it was resolved that if the Government failed to provide the necessary funds, an appeal should be made to the States of Baden, Bavaria, Alsace-Lorraine, Hesse and Prussia.

THE lectures at the Royal Institution of Great Britain will be resumed on Tuesday, February 5, when Prof. J. A. Ewing will deliver his third lecture on "Practical Mechanics (Experimentally Treated)—First Principles and Modern Illustrations"; and on Wednesday, February 6, Prof. R. K. Douglas will deliver his second lecture on "The Government and People of China." The Friday Evening Discourse, on February 8, will be delivered by Prof. G. H. Bryan, his subject being "The History and Progress of Aërial Locomotion."

WE learn from the *Times* that the question of the protection of Stonehenge from further damage was discussed at a recent meeting of the council of the Society of Antiquaries, when a resolution was passed offering to co-operate with the owner of this ancient monument, Sir Edmund Antrobus, for its protection, and suggesting that a scheme might be arranged with that object in view. A copy of the resolution has been forwarded to Sir Edmund Antrobus, and his reply will be considered at the

next meeting of the Society. The general opinion in Salisbury and district is that Stonehenge ought to be purchased by the nation, but the price which was mentioned some time ago is regarded as too great.

THE Right Hon. R. W. Hanbury, M.P., President of the Board of Agriculture, has appointed a committee for the purpose of conducting experimental investigations with regard to the communicability of glanders under certain conditions, and as to the arresting and curative powers, if any, of mallein when repeatedly administered. The committee will consist of:—Mr. A. C. Cope, chief veterinary officer of the Board of Agriculture (chairman); Prof. J. McFadyean, principal of the Royal Veterinary College; Mr. William Hunting, one of the veterinary inspectors of the London County Council; Mr. J. McIntosh McCall, assistant veterinary officer of the Board of Agriculture. Mr. A. H. Berry, of the Board of Agriculture, will act as the secretary to the committee.

IT is proposed in Dundee to erect a granite monument over the grave of James Bowman Lindsay, in the Western Cemetery of the city. Lindsay was a very remarkable man, whose memory should not be permitted to fade. He was born in 1799, and taught electricity, magnetism and other subjects in Dundee for many years, dying there about forty years ago. In 1834 he foresaw that "houses and towns will in a short time be lighted by electricity instead of gas, and machinery will be worked by it instead of steam." This prediction was the result of his own observations of effects produced by the electric current, and not merely imaginative suggestions. In 1854 Lindsay transmitted telegraphic signals through water electrically; and when the British Association visited Aberdeen in 1859, he demonstrated the success of his method by transmitting signals across the harbour. He also read a paper upon it, entitled, "Telegraphing without Wires." Sir John Leng has set on foot the scheme to commemorate the genius of Lindsay by a suitable memorial, and there should be no difficulty in raising the modest amount required for that purpose.

ON Saturday night and Sunday last the metropolis, and indeed all parts of the British Islands, were visited by a storm of great severity. The storm approached from the Atlantic so rapidly that very little notice of its appearance was visible a few hours previously. On Saturday morning the centre of a large depression which had passed to the north of Scotland lay over the north of Sweden, and the only indication of the approach of another serious disturbance was that the wind in the south-west of Ireland showed no inclination to veer beyond west. But the telegraphic reports received by the Meteorological Office showed that in the course of Saturday night the wind had rapidly increased, and on Sunday morning the centre of the storm lay near the north of Scotland. Its influence was felt as far as the south of France, and without doubt far to the north of Scotland. The gusts were very violent, and caused much damage to trees and buildings, the pressure at Greenwich amounting to 34·4 lbs. on the square foot about noon on Sunday, which is equivalent to force 11 of the Beaufort notation. By Monday morning the centre of the disturbance lay over the Baltic, but the interruption to telegraphic communication was so great that scarcely any reports from Northern Europe reached this country in time to be available for the ordinary weather forecasts. Smart showers of hail, snow and rain occurred in most parts of the country.

THE Shanghai Meteorological Society has published its seventh annual report, containing much useful information relating to the atmospheric conditions and movements in the far East. As an appendix to the report an atlas is published showing the mean isobars and the mean directions of the wind for each of the six winter months. The number of stations in the Chinese Empire is too limited to allow of precise information being given, but all that was available, relating to the sea and adjacent shores, has been collected and carefully collated. The average number of storms varies from two in October to four in November, December and January, and five or six in February and March. The general direction of the storm track is E.N.E. with a tendency to bend to N.E. The violence of the storms seldom attains the intensity of a true hurricane; force 10 or 11 of the Beaufort scale is seldom recorded. The report is drawn up by the Rev. A. Froc, S.J., director of the Zi-ka-wei Observatory.

MR. W. MCDOUGALL contributes to *Mind* (January 1901) some new observations in support of Thomas Young's theory of colour-vision. The author has attempted a re-examination of the fundamental and comparatively simple phenomena of vision, and he describes in some detail certain phenomena which he designates "the complete fading of visual images" and "the mutual inhibitions of visual images." The author is unaware of any previous mention of these phenomena, and he applies the knowledge derived from their study to an exhaustive examination of the question of a separate black-exciting process, comparable to the processes that excite the sensations of colour. It is shown that the assumption of such a process is unnecessary and groundless.

A SHORT time ago we noticed a paper, by Signor C. Viola, on the law of rationality of indices in crystallography. A much more exhaustive examination of the actual basis of the thirty-two classes of crystals is now given by Mr. William Barlow in the *Philosophical Magazine* for January. Mr. Barlow's proofs are based on the fundamental assumption of a molecular structure combined with a suitable definition of homogeneous structure. This definition implies the existence of points distributed evenly at regular intervals through the mass, such that the aspect of the structure, viewed from all such corresponding points, is the same, but that an inferior limit to the distance between corresponding points always exists. The method of arriving at the thirty-two classes combines some of the arguments used by Sohncke with some of those used by Gadolin and others, and the paper includes a discussion of Haüy's law.

SOME new experiments by M. G. Sagnac on the transformations of Röntgen rays by matter are summarised in No. 157 of the *Bulletin* of the French Physical Society. The study of the electric action of the secondary rays emitted by a body affords a test of the presence of small quantities of relatively active substances such as copper, iron, aluminium. Hence, also, a method of searching for new elements. The energetic absorption of the more active rays from such a metal as platinum in the first few millimetres of adjacent air has been verified directly by rarefying the air surrounding the metal. Finally, a pencil of Röntgen rays discharges a conductor even when it does not pass through the portion of air acted on by the electric field of the conductor. It is sufficient that the rays shall traverse a portion of air separated from the field of the conductor by a Faraday screen (such as a metal gauze), and that there shall be a field of force in the part traversed, of like sense to that due to the conductor. If the charge of the conductor is reversed in sign, the rate of discharge is altered in the ratio of 1 to 10 or 20, but in the absence of the field in the second region no such change takes place. M. Sagnac's explanation of the phenomena is that the ions produced in the second region acquire, under the influence of the external field, sufficient kinetic energy to carry them through the openings of the screen into the region surrounding the conductor.

THE melting-point of gold is an important fixed point in pyrometry, and its exact determination has been attempted by several observers. In this country the electrical resistance pyrometer has been regarded as the most trustworthy instrument, the mean result obtained by its use being given by Messrs. Heycock and Neville as 1061·7° C. In the January number of *Wiedemann's Annalen* there is a further paper on this subject by Messrs. L. Holborn and A. Day. These observers prefer a thermo-couple that has been directly standardised against an air thermometer as their measuring instrument. In their previous papers these authors have described a method in which the melting-point of a small piece of gold wire is determined. On account of the possibility of the result being influenced by the minute amount (·03 gram) used, it appeared desirable to redetermine the constant by the crucible method. The temperature of 450 grams of solidifying gold was measured with a thermo-couple in crucibles of graphite, porcelain and clay, the atmosphere above the fused metal being either air, carbon dioxide, or oxygen. The mean result was 1063·5° C. The same sample of gold gave 1063·9° C. by the wire method.

THE Board of Trade has received, through the Foreign Office, copy of a memorandum by H.M. Consul at Milan respecting an electrical smelting process carried on in North Italy under Captain Hassano's patent. The memorandum states that the feature of Captain Hassano's process is the substitution, in the smelting of iron ore, of heat produced by electricity for that produced by coal, and the merit he claims for it is economy. His experiments were begun in Rome, but have now for some time been carried on, under his personal superintendence, by a company formed for the purpose, at Darfo, in the Province of Brescia, where a considerable water-power is available. At the end of last month a commission composed of five well-known scientific men spent two days at Darfo and witnessed a series of experiments. These gentlemen have now issued a very brief report to the effect that they consider the Hassano process to be industrially practical. The Consul states, however, that he has consulted several very competent authorities at Milan who have carefully followed the development of Captain Hassano's invention, and they are all of opinion that as yet no adequate proof has been furnished that the new system will not cost more rather than less than the one actually in use. Moreover, its application, with any prospect of success, appears to be dependent on the possession of a very abundant water-power, at a very low price, for the production of the electric energy, the consumption of which is enormous.

MR. J. B. C. KERSHAW'S paper on "The Use of Aluminium as an Electrical Conductor," which was read before the Institution of Electrical Engineers on January 10, contains an account of some interesting experiments made by the author on the durability of aluminium under different atmospheric conditions. The results show that the commercial aluminium at present obtainable is by no means perfectly resistent to atmospheric corrosion, but becomes seriously pitted after ten months' exposure, especially in the air of towns. Unfortunately the scientific value of the experiments is diminished by the fact that, although the aluminium used had only a purity of 99 per cent., no analysis of the samples was made. According to Moissan, pure aluminium is quite stable, but the presence of a very small quantity of sodium destroys this stability. It is to be hoped that Mr. Kershaw, in his further experiments, will carry out a more thorough investigation of this point, as it is one of great importance. The paper shows how enormously aluminium has decreased in cost in the last ten years, until it has now become, by virtue of its cheapness, a formidable rival to copper. Some interesting details are given of aluminium transmission lines which have been, or are being, erected in America, which show that country to be far in advance of England in this, as in most other, enterprises.

IN the *Victorian Naturalist* for December Messrs. Fulton and Grant record the occurrence of the European shore-crab (*Carcinus moenas*) in considerable numbers in Port Phillip. If, as seems probable, the species is introduced, it is the first instance of the intrusion of a European marine type into the Australian fauna, and the progress of the intruder will be watched with interest. To the same number Mr. D. le Souëf contributes notes on some little known Australian birds' eggs.

IN the January number of the *Zoologist* Mr. T. Southwell, of Norwich, describes a recent visit to the fish-wharf at Lowestoft, in the course of which he shows how much information is to be gleaned with regard to our fish-fauna from such an inspection. Among the uncommon captures was a porbeagle shark nearly eight feet in length. The author adds that all the animals seen at Lowestoft must not be regarded as British, mentioning the case of the so-called prawns of the genus Nephrops, large numbers of which are brought in from the North Sea.

To the same journal Mr. G. Leighton contributes an account of an extraordinary "plague" of snakes which has recently occurred in a house at Cefncaeau, near Llanelly, South Wales. During September, according to a newspaper report, the place had become a domicile for swarms of these reptiles. "They crawled over the floors, infested the cupboards, curled themselves together on the furniture, while some more aspiring members of the species climbed the stairs and luxuriated in the comforts of the bedrooms. The human occupants of the house had done their best to rid themselves of these unwelcome visitors, and had waged a war of extermination against them. The snakes continued to come, however, although, as the inspector explained, no fewer than twenty-two were slaughtered in one day." As might have been expected, the species proved to be the common grass, or ring-snake. The eggs from which the twenty-two individuals mentioned above were hatched were probably deposited by the parent behind the oven, or in a hole in the back wall. On taking down a portion of the latter wall no fewer than forty bunches, each containing thirty eggs, were discovered, all being on the point of hatching. There were thus some twelve hundred snakes in an area of a few square feet.

THE December issue of the *Agricultural Journal* of New South Wales contains the conclusion of an interesting communication by Mr. W. J. Allen on olive culture in the Colony, illustrated with seven plates showing the fruit of the various varieties that have been raised there. The author lays great stress on the importance of cultivating only such varieties as have been proved to be suitable to the Australian climate and soil, and are, at the same time, noted for their abundant yield of oil. How great is the difference in the latter respect between different strains is shown graphically by photographs of a series of equal-sized flasks containing the products of equal quantities of olives. In the case of two varieties the yield is a flask and a half, or more, whereas some of the inferior strains yield not more than one-sixth of a flask.

WE have received the fifth of the excellent series of *L.M.B.C. Memoirs* now in course of issue under the able editorship of Dr. Herdman, the present fasciculus, which is by Dr. Hickson, dealing with *Alcyonium*, the zoophyte commonly known as "dead men's fingers." The anatomy, development and physiology of this curious compound form are severally treated in considerable detail, the whole account forming a model of how such a subject should be treated. When an Alcyonium colony has all its polyps fully protruded, the whole

organism is in a state of activity; but this could not go on incessantly, and the periodical retraction of the polyps seems to mark intervals of rest. These periods of rest and activity appear to be correlated, not with night and day, but with low and high tides; and it seems probable that Alcyonium takes a rest at each low tide, that is, twice in every twenty-four hours. Owing, however, to the unsatisfactory conditions obtaining in aquaria, it has not yet been found possible to ascertain the duration of these periods of repose in a state of nature. The author adds that in a large fleshy mass like Alcyonium it is obvious that there must be some general system of circulation, and in the absence of rhythmically contractile organs it is equally obvious that such circulation must be maintained by ciliary action.

MUCH interesting and important information with regard to food-fishes is afforded by the Report of the Northumberland Sea-Fisheries Committee for 1900, edited by Mr. A. Meek. The flat-fishes, collectively, give an average of 231 in the "takes," which is a considerable improvement over the previous year; but this is almost entirely due to an increase in the number of dabs, plaice having diminished to a marked degree, while turbot have, unfortunately, become exceedingly rare along the coast. It is, however, gratifying to notice that the catch of soles shows a slight improvement over those of the two previous years. Very few floating eggs were obtained, the explanation being that the work was done in harbour during summer, and that the fringe of water near the coast is also the fringe of the great area of water outside where the spawning and hatching take place. A short statement by Prof. Brady is made with regard to the pelagic fauna obtained with the eggs, while Mr. Bulman treats of the molluscs, and the editor of the shrimp-like mysids and the curious crustaceans included under the name Cumacea. These latter may seem to have but a remote connection with fisheries; but as they contribute, directly or indirectly, to the food of fishes, crabs and lobsters, their inclusion in the Report is fully justified. The results of the hatching experiments conducted during the early part of the year show that the work of the fertilisation of the ova of ripe fishes caught by the trawlers must be done at sea soon after the capture of the fishes. An experiment in mussel cultivation has been undertaken, the results of which will be published in the next Report.

A FEW particulars concerning the bird-catching industry in the Faroe Islands are given in the *Board of Trade Journal* (January 24). Among the various species which make the isles a country of birds, the following may be specially mentioned: the guillemot, the auk, the puffin and the kittiwake. During a certain part of the summer they appear in such numbers on and around the "fowling cliffs" as to suggest resemblance to a thick snow-storm of living winged creatures. In the Faroe Isles a "fowling cliff" means a perpendicular cliff, the numerous shelves of which are covered with guillemots and auks. The puffin and the kittiwake are also often found here, but not necessarily always. The "fowling cliffs" all face towards the west—that is, from south-west to north-west. There are also perpendicular cliffs facing towards other points of the compass, but scarcely any birds are found on these. The puffin is the most important bird in the islands, and about 100,000 are caught annually. Twenty-four of these birds yield one pound of feathers. A few years ago a number of grouse were let loose on the islands, and it appears that they have thriven well on some of the northern isles, where several flocks may be seen.

A TRIPLE horizontal pendulum of the Rebeur-Ehlert type has recently been erected for the study of earthquakes at Hamburg. Dr. R. Schütt, who has charge of the instrument, has published the first of a series of monthly *Mittheilungen*, dealing with the earthquakes registered during October 1900.

IN a short paper contributed to the Roumanian Academy, and published in vol. xxii. of the *Analele*, Dr. S. C. Hepites describes the Roumanian earthquakes of 1899. They were all of slight intensity, and occurred on January 12, August 6 and 9, October 10, November 13 and December 20.

MR. JAMES MCEVOY reports on parts of Alberta and British Columbia (Geol. Surv. Canada, *Ann. Rep.*, part D, vol. xi, 1900). His observations were made in a traverse of the Yellow Head Pass route from Edmonton, on the North Saskatchewan river, to Tête Jaune Cache. Rocks of Archæan, Cambrian, Devono-Carboniferous, Cretaceous and Tertiary ages are recorded, as well as Glacial and other superficial deposits. Gold is noted in the Lower Cambrian areas, and some thick seams of coal in the Lower Laramie (Cretaceous) strata.

DR. J. F. WHITEAVES contributes descriptions of some new and imperfectly-known fossils from the Cretaceous rocks of the Queen Charlotte Islands (Geological Survey of Canada, "Mesozoic Fossils," vol. i. part 4, 1900). As he remarks, the progress of palæontological research during the fourteen years which have elapsed since the third part of his work was published, necessitates alterations in nomenclature. A fossil was previously identified as *Ammonites Beudanti*, and placed in the genus *Haploceras*: since then the Ammonite has been regarded as a *Desmoceras*, and more recently it has been referred to the subgenus *Puzozia*. Dr. Whiteaves deems it prudent to give the Canadian fossil a new specific name, so the Ammonite now stands as *Desmoceras* (*Puzozia*) *Dawsoni*. This is a good illustration of the heartrending though needful changes brought about by the detailed study of fossils. A number of new species of Mollusca and Brachiopoda are now described and figured by Dr. Whiteaves. One British species, *Inoceramus concentricus*, is recorded.

AUSTRALIA offers a wide field of work for those experienced in the industrial utilisation of vegetable products. Although the practical value of economic botany remains imperfectly understood throughout the Commonwealth, there are not wanting indications of its approaching recognition as a new and valuable source of national wealth. Recently, in New South Wales, Mr. R. T. Baker, the curator and economic botanist of the Sydney Technological Museum, appeared as a witness before a Royal Commission appointed to inquire into the condition of the western lands of the State. In the course of his examination he produced samples of eucalyptus oil in various stages, extracted from trees in the eastern portions of New South Wales, and stated that the colony now produces eucalyptus oil of the highest quality, fully equal to the best in the market. He said that a large amount of research has lately been made in connection with the flora of that part of the parent State, with very valuable results. For instance, myrticolorin, a new dyeing material, has been obtained from the leaves of the red stringy bark, in addition to the valuable oil extracted from the same source. Out of trees and shrubs in the eastern portion of the State, Mr. Baker has, with the assistance of his staff, extracted camphor, perfumes (such as otto of roses, ionone and cinnamon), dyes, peppermint and cajuput—oils which ought now to be pushed on the market. New South Wales can also compete against India and Bulgaria with its geraniol extract. Mr. Baker's evidence went to show that the vegetable products of the western, or dry country, in New South Wales, possesses an economic value not inferior to those of the eastern or coastal districts. It may be mentioned that there are in the west, as in the east, many millions of eucalyptus trees of various

kinds, the trees and shrubs from which oils, resins, dyes, tans and other products can be obtained being several hundred in number.

THE current number of the *Proceedings* of the Royal Society contains a paper of much interest to all who are devoted to the canine race. It describes Dr. Copeman's successful endeavours to isolate the micro-organism responsible for distemper in dogs. The investigations here recorded are a continuation of work begun some ten years ago by the late Everett Millais at St. Thomas's Hospital. Dr. Copeman has now isolated a small cocco-bacillus, growing readily on most of the ordinary culture media at the body temperature, from the exudations from the lungs, the tracheal mucus, and from the nasal secretion of dogs suffering from distemper. A cubic centimetre of a broth-culture of this microbe, injected beneath the skin of the abdomen in a dog weighing 7 kilograms, is sufficient to induce an attack of distemper terminating fatally in about a week from the date of inoculation. A vaccine has also been prepared which Dr. Copeman states can protect dogs against attacks of distemper. This vaccine is procured by heating a broth culture of the bacillus at 60° C. for half an hour, and then adding a small quantity of carbolic acid. An injection of 2 cubic centimetres of such vaccine was apparently sufficient to protect fox-terrier pups weighing about $1\frac{1}{2}$ kilograms when exposed to distemper infection. How long this immunity is retained by dogs has not yet been ascertained, but information on this and other important points connected with this discovery may shortly be expected, as Dr. Copeman tells us that a series of tests on a large scale are in process of being carried out by dog-breeders in this country, as well as in Germany and America.

WE are very favourably impressed with the first number of the *Journal of Hygiene*, which has just been issued. Messrs. Nuttall, Cobbett and Strangeways-Pigg contribute a paper, illustrated with maps, on the geographical distribution of *Anopheles*, the malarial mosquito, in England, and Messrs. Nuttall and Shipley the first part of a paper on the structure and biology of the same insect. Species of *Anopheles* seem to have been met with in all the districts examined, and not only in those where malaria was formerly prevalent. Dr. Klein, dealing with the pathogenic microbes of milk, has found the tubercle bacillus to be present in 7 per cent. of the samples examined, a figure which accords well with our own experience. Dr. Legge discusses industrial lead poisoning, and Dr. Newsholme the utility of isolation hospitals in diminishing the spread of scarlet fever. Dr. Haldane describes an apparatus for the rapid determination of carbonic acid in air. The apparatus is quite portable (the inclusive weight being only about six pounds), and has an accuracy of 0·5 vol. per 10,000. Dr. Haldane also contributes a paper on the red colour of salted meat, and finds it to be due to nitric-oxide-hæmoglobin. This is formed by the action of a nitrite on hæmoglobin in the absence of oxygen and in the presence of reducing agents, the nitrite resulting from the nitre in salting by reduction, probably through the agency of bacteria. When boiled it is changed into nitric-oxide-hæmochromogen. Messrs. Lorrain Smith and Hoskins find that ethylene does not contribute to the poisonous action of coal gas. Dr. Ritchie discusses the artificial modifications of toxins under the influence of acids and alkalies. The *Journal*, which is edited by Drs. Nuttall, Haldane and Newsholme, is to be issued quarterly, and is published by the Cambridge University Press. The present part is illustrated with figures and diagrams in the text, with a double plate illustrating the structure of *Anopheles*, and with a beautiful coloured plate of *A. Maculipennis*.

THE *Reliquary and Illustrated Archaeologist* has its usual well-illustrated articles on various matters of antiquarian interest. We need only call attention to a paper by Mr. W Heneage Legge on some churches in the Hundred of Willingdon in Sussex; one by Mr. J. K. Floyer on "A thousand years of a Cathedral Library" (Worcester). Miss Florence Peacocke draws attention to needlework maps, which were sometimes veritable works of art. John Schorne, a mediæval worthy, is the subject of a paper by Mr. T. Hugh Bryant. This popular preacher of the early fourteenth century was accredited a saint by public opinion because he "conjured the devil into a boot." This may be the origin of the popular tavern sign "The Boot," and may also have given rise to the toy known as "Jack-in-the-box."

IT has been stated that the inhabitants of the Mentawei Islands, which lie off the west of the coast of Sumatra, are more nearly allied to the Polynesians than to the Malays; but in a beautifully illustrated account of these islanders in *Globus*, Mr. C. M. Pleyte denies this resemblance, in which he is certainly corroborated by the illustrations, and states that they are allied to the Battak. Mentawei is derived from the Malay *matäu*, "man," pronounced locally *matawi*. The natives call themselves Tschakalägät. The men and women are tattooed in straight and slightly curved lines, and occasionally bird designs, on various parts of the body, but the men are more ornamented than the women; it is a necessary preliminary to marriage. It is interesting to note the bow and arrow is employed; the arrows used in warfare are poisoned; the blow-pipe is unknown. The religion appears to be shamanistic; men and women may be shamans (Pleyte terms them "priests"). There are numerous prohibitions, or taboos (*punän*). Divination is performed by an examination of the viscera, especially the stomach, of pigs and fowls. The paper is a valuable record of the ethnography of a people practically unaffected by external influence.

THE Canadian Institute could not have chosen a more appropriate way of commemorating the first fifty years of its history than by the publication of the fine memorial which forms vol. vi. of the *Transactions* of the Institute. The papers in the volume cover a wide field of scientific activity, and do honour to Canada. Sir Sandford Fleming, who was the first secretary and the real founder of the Institute, should be gratified at its growth and influence. The Institute has encouraged scientific study and investigation, and their applications to practical results. It has placed a vast amount of varied knowledge at the disposal of the public, and its recommendations have for many years been received with respect in the official as well as the scientific worlds. One subject of great interest, which first engaged the attention of the Institute twenty years ago, and with which the name of Sir Sandford Fleming is prominently associated, is the zone system of time-reckoning. On the action taken by the Institute, a discussion was inaugurated which extended eventually to Great Britain, and afterwards to all civilised nations, with the result that the essential principles of the system recommended have been adopted on all the five continents. Countries are being brought into the zone system one by one, even though all of them have not adopted the twenty-four hour notation. In other matters the Institute has taken the lead, and has contributed in no small degree to the increase of knowledge in letters, art and science in the Dominion of Canada. We can only mention a few of the subjects dealt with in the volume, namely, the geological history of Lake Superior, the decipherment of the hieroglyphic inscriptions of Central America, the magnetic influence of the sun on the earth and on comets, the structure, microchemistry and development of nerve-cells, the cytology of non-nucleated organisms, the anatomy of the orang-outang, and the morphology of the central cylinder in the angiosperms.

THE following lectures will be delivered during February at the Royal Victoria Hall, Waterloo Road, at 8.30 p.m. :—February 5, "Germs, Our Friends and Foes," by Mr. J. E. Purvis; February 12, "The Eastern Hemisphere," by Mr. E. J. Garwood; February 19, "An Old English Chemist of the Seventeenth Century," by Dr. Donnan; February 26, "Life of the Natives of Sarawak," by Prof. Haddon.

THE new volume of "The Englishwoman's Year Book and Directory for 1901" (A. and C. Black) has been overlooked until now. The value of this annual lies in the fact that it is a guide to spheres of activity open to women, and a summary of women's contributions to intellectual progress during the past year. The scientific summary is not complete, but it serves to show that women are assisting in the advancement of many departments of natural knowledge.

THE only journal in the world devoted entirely to the study of ophthalmological refraction is the *Dioptric and Ophthalmometric Review*, published for and by the Council of the British Optical Association. In addition to the articles, abstracts and notes of special value to opticians, the review contains contributions of interest to all students of optical science. We notice, for instance, descriptions of recent optical patents, and the questions set at the examination of the British Optical Association in December.

THE additions to the Zoological Society's Gardens during the past week include three Martinican Doves (*Zenaida aurita*) from the West Indies, presented by Mr. D. Seth Smith; a White-backed Piping-Crow (*Gymnorhina leuconota*) from Australia, presented by Miss Crowder; a Peregrine Falcon (*Falco peregrinus*), European, presented by Mr. Alfred Ficken; a Greater Black-backed Gull (*Larus marinus*), European, presented by the Hon. Mrs. Barnett; a Himalayan Monkey (*Macacus assamensis*) from Northern India, a Mozambique Monkey (*Cercopithecus pygerythrus*) from East Africa, a Two-spotted Paradoxure (*Nandinia binotata*), a Grey Parrot (*Psittacus erithacus*), a Shining Weaver Bird (*Hypochera nitens*) from West Africa, a Barbary Wild Sheep (*Ovis tragelaphus*) from North Africa, a Barbary Falcon (*Falco barbarus*) captured in the Red Sea, nine Ceylonese Terrapins (*Nicoria trijuga*) from India, deposited; a Naked-throated Bell-bird (*Chasmorhynchus nudicollis*) from Brazil, purchased.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN FEBRUARY.

Feb. 1. 6h. 32m. to 7h. 18m. Moon occults D.M. + 17°, 1596 (mag. 5·6).
2. 17h. 20m. to 17h. 42m. Moon occults A¹ Cancri, (mag. 5·6).
2. 18h. 57m. to 19h. 47m. Moon occults A² Cancri, (mag. 5·8).
3. 14h. 34m. to 15h. 37m. Moon occults ω Leonis, (mag. 5·6).
9. 17h. 38m. to 18h. 53m. Moon occults B.A.C. 4700 (mag. 5·3).
14. Venus. Illuminated portion of disc = ·949, of Mars = ·997.
14. Saturn. Outer minor axis of outer ring = 15″·08.
14. 17h. Jupiter in conjunction with the moon. Jupiter 2° 51′ S.
14. 19h. 7m. Jupiter's Satellite IV. in conjunction N. of the planet.
15. 11h. 20m. Minimum of Algol (β Persei).
18. 8h. 9m. Minimum of Algol (β Persei).
19. 10h. Mercury at greatest elongation, 18° 6′ East.
20. 1h. Mercury in conjunction with the moon. Mercury 3° 29′ S.
21. 6h. 54m. to 7h. 51m. Moon occults 51 Piscium (mag. 5·7).
21. 18h. Mars in opposition to the sun.
22. 10h. 20m. to 11h. 7m. Moon occults π Piscium (mag. 5·6).
24. 16h. 20m. to 19h. 13m. Transit of Jupiter's Satellite III.

BROOKS' MINOR PLANETS.—Referring to the recent note in NATURE (January 3) announcing the discovery of three new minor planets near to Eros, Herr Kreutz publishes, in the current issue of the *Astronomische Nachrichten*, Bd. 154, No. 3682, a telegram from Prof. E. C. Pickering, of Harvard College, saying: "Brooks' asteroids not confirmed on simultaneous plate; stars near position given."

BRORSEN'S COMET.—In the *Astronomische Nachrichten* (Bd. 154, No. 3681), A. Berberich gives an ephemeris to facilitate the search for the expected return of Brorsen's Comet this year.

Ephemeris for 0h. Berlin Mean Time.

Observations of the Comet by R. G. Aitken with the 36-in. Lick refractor showed it as irregular in outline, with a condensation south—preceding the centre, and a small fan-shaped extension in the north—following quadrant.

REFRACTION WITHIN TELESCOPE TUBE.

IT has been supposed that the difference between the zenith-distance of a star obtained by direct observation and that obtained by observing it reflected in a pool of mercury—as it is not fully explicable as the result of the flexure of the telescope-tube—is partly to be accounted for as the result of abnormal refraction in the neighbourhood of the instrument, owing to varying air-temperatures in the room. It is *within the tube of the instrument* that these things are to be looked for.

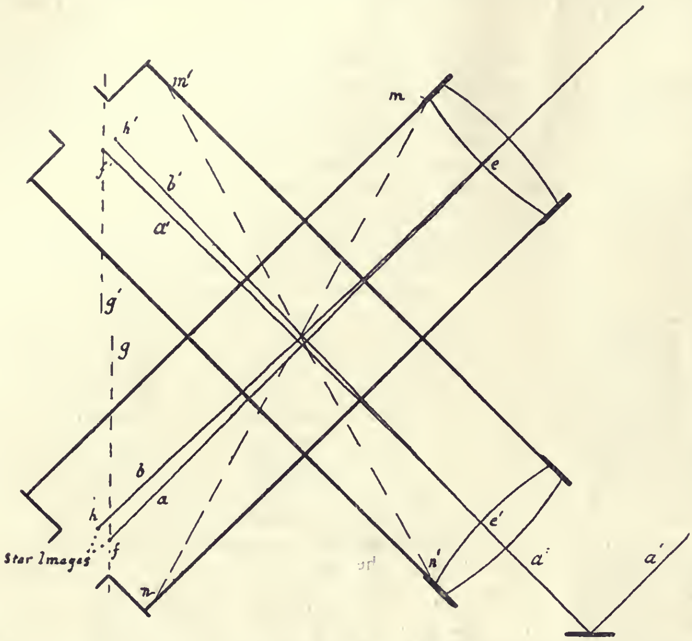

Fig. 1.—*a*, *a'*, Rays normally refracted by horizontal stratification of air. *b*, *b'*, Rays refracted by stratification of air parallel to *mn*, *m'n'*, (inverted refraction). *mn*, *m'n'*, Equal-density surfaces when upper side of tube is cooled.

The air within a room where there is no powerful source of heat and where currents are caused by open shutters, &c., must be very nearly uniform in temperature; neither would it prove the contrary to obtain varying readings of the thermometer within the room, such readings being much affected by radiation from the walls, &c. On the other hand, the air within the telescope-tube must commonly be stagnant, and any cause operating to produce differences of temperature therein will do so effectually. Now in making any observation at considerable zenith distance the upper side of the tube is cooled by radiation, while the lower is protected, and the resulting difference of temperature in the metal of the tube is communicated to the air within, to an extent depending on the time of exposure.

In the diagram (Fig. 1) showing the telescope in the two positions of observing—direct and reflex—the rays *a*, *a'*, are normally refracted and convex upwards, as they would be with horizontal stratification of the air. At any two points at the same level these rays (supposed from the same star) have the same inclination to a vertical line; therefore the zenith distances that would be observed with such refraction (angle *e*, *f*, *g* direct and *e'*, *f'*, *g'* reflex) would be the same—neglecting flexure and the difference of latitude between the trough and instrument. But this result depends on the supposed parallel (viz. horizontal) stratification of the air throughout the course of both rays. When there is a transverse gradient of temperature in the tube owing to the cooling of its upper side and the contiguous air within, the equal-density surfaces are inclined like *m*, *n*, *m'*, *n'*—a difference of temperature of only two-tenths of a degree Fahrenheit will make the air at *m* as dense as it is at *n* if these points differ in level by ten feet—and the stratification of the air, being no longer parallel in the two cases, two different zenith-distances will be obtained. The rays within the tube will then be convex downwards, *b*, *b'*—"inverted refraction"—and the direct observation will give a result in excess of the reflex one by twice the angle *f e h*. So if the results were only affected by this process the Reflex-minus-Direct results would be ***negative***. The R – D results obtained in the Greenwich observations are commonly *positive* by reason of the flexure of the tube, and are *reduced in magnitude* by inverted refraction.

In the diagram (Fig. 2) the curve *a* shows the R – D results that would be obtained if affected by instrumental flexure only; from the formula 2(0″·80 sine zenith distance). This value 0″·80 I take to be nearly the correct horizontal flexure (see below). The curve A shows the mean results obtained for the values of R – D in the years 1892–3–4 for south stars, *reflex observation taken first*. The curve B shows the same results for north stars. The curve C shows a special series of R – D results obtained in the year 1894, all from south stars, the direct observation being made first. The differences between these curves severally and the flexure curve *a* are accounted for by the inverted refraction in the tube, and the various values of these differences for the three curves are readily explained:—

(*a*) The north-star-curve differs more from the flexure-curve than the south-star-curve does; the difference in both cases is due to the exposure of the instrument in the position directed to the star (chiefly in the reflex position); but in observing a north star the time of exposure is commonly greater than in observing a south star, as the observation in right ascension is made at the same time, and a slow moving polar star requires more time for this purpose.

(*b*) From Fig. 1 it is apparent that it is at the object-glass end of the tube that the inverted refraction is most effective in separating the star image *h* from the position *f*, where the normal refraction would place it; and of the two observing positions of the instrument, the direct one chiefly affects the object-glass end by radiation, because in this position it is near the open shutter. In the observations from which the curves A and B are deduced,

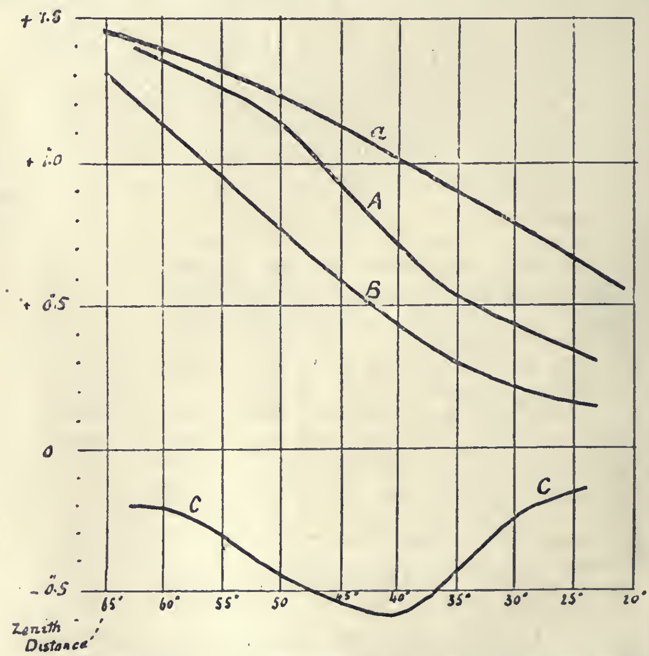

Fig. 2.—*a*, Flexure curve, 2(0″·80 sine zenith distance). A, R – D curve, south stars, reflex observation taken first. B, R – D curve, north stars, reflex observation taken first. C, R – D curve, south stars, direct observation taken first.

the reflex observation is made first, and the instrument is then turned in mid-transit to the direct position, in which the exposure is of very short duration before the observation in zenith distance is made. In the curve C, for which in each case the direct observation was made first, the exposure in the direct position would commonly be considerably greater; and the difference between this and the flexure-curve, attributable to such exposure, is accordingly much greater than the same differences for the A and B curves. Note that the difference becomes smaller under 40° zenith distance; it would be zero in the zenith in all cases.

Other instances of apparent refraction within the tube are found in the Greenwich observations:—

When the north and south collimators are alligned by looking through the holes in the telescope-cube, the collimation-error obtained differs systematically from that obtained by alligning the collimators with the telescope raised out of the way. This can only be explained thus: one side of the instrument is commonly warmer than the other at the hour (8 a.m.) when these observations are made, and the still air in the tube is affected in like manner. If we suppose the air in the spaces A and B, Fig. 3, to differ from each other 0° 5 Fahr. in temperature, and to be separated by a surface which the path of the light between the north and south collimators cuts at an angle of incidence of 80°, the light will be deflected $0''\cdot60$ of arc, and the collimation-error obtained would be in error by half this amount, viz., $0''\cdot30$,

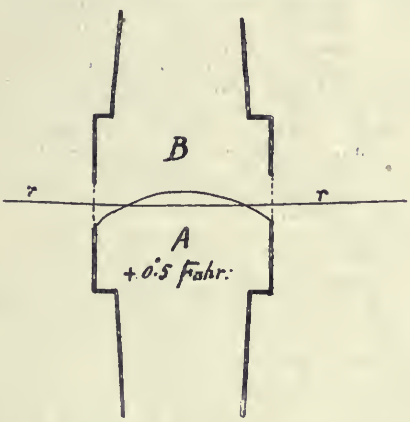

FIG. 3.—r, Shows path of light from north to south collimator refracted within cube of telescope when air is unequally heated.

which is about the difference between the values obtained by the two methods.

A similar discordance exists between the results for flexure of the tube formerly obtained by raising the telescope and those recently obtained by alligning the collimators through the cube; and this discordance has a similar explanation. The flexure obtained formerly, which I take to be the more correct, is about $0''\cdot80$ of arc, as employed above to explain the R – D discordance.

I conclude that means should be provided—and used—for circulating the air in the tube when any observation—whether of star, of collimation, or of flexure, or otherwise—is made with a transit circle. I would also point out that the source of error here considered is of peculiar importance from the fact that it affects, to a relatively large amount, the zenith-distances of polar-stars, and hence the deduced results for latitude. The error is eliminated in the mean of a reflex and a direct observation taken at the same time.

JAMES RENTON.

SUGAR-CANE EXPERIMENTS.

IN the fourth number of the *West Indian Bulletin*, recently noticed in these columns, many pages were devoted to communications to Dr. Morris, the Imperial Commissioner of Agriculture, from Prof. d'Albuquerque, the Island professor of chemistry, and Mr. Bovell, the agricultural superintendent, in which an elaborate plan was laid down for undertaking an exhaustive investigation into the merits of several varieties of sugar-canes. The very full details therein given should be consulted by any one desirous of mastering the significance of the facts contained in the pamphlet now issued by the Commissioner, giving a "summary of the results of the cultivation of seedling and other canes at the experiment stations in Barbados in 1900." Prof. d'Albuquerque and Mr. Bovell have read a paper on the subject before the Barbados Agricultural Society on the results of the cultivation and yield of selected seedling and other canes, and the pamphlet summarises the essential facts. It is important to remember that the experiments were throughout conducted on the ordinary system of natural cultivation, the planters themselves undertaking to set apart plots of their own plantations, so that the known and the unknown grew side by side, no exceptional treatment being recognised. In this way fairly typical results are obtained, and the results for subsequent years will, therefore, be watched with more than usual interest to see how the character of the season, as well as the quality of the soil, may affect the various canes. For the experiments seven stations were selected, representing the typical soils and climatic conditions of Barbados. Five of the stations were black soil, the other two red soil. At nearly every station there were duplicate plots of each variety, serving to show the variation to be expected with each variety from one part of the field to another. The lowest station was at an elevation of 100 feet above sea-level, the highest 910 feet, the rainfall in the growth period ranging from 56 inches to 89 inches. Fifteen selected varieties of canes were tested on the black soil estates, and ten of them on the red soil estates. For each variety the highest and the lowest yield in tons per acre in the black and the red soils respectively are given, and separate tables for black and red soils show for each cane the number of plots used for the investigation, the yield in tons per acre of canes and also of tops; the juice per cent. by mill; pounds per gallon of saccharose, of glucose and of solids not sugar; the quotient of purity of the normal juice; the juice in gallons per acre; saccharose in pounds per acre; and the sugar in tons per acre, calculated according to a formula supplied by Mr. Douglas, of the Diamond plantations, British Guiana. In the black soil B. 147 heads the list with 3·01 tons of sugar per acre, followed by B. 347 with 2·90 tons, and B. 208 with 2·83 tons, while at the bottom of the list stand D. 145 with 1·82 tons, the Burke with 1·73 tons, and the Bourbon with only 0·47 ton per acre. The White Transparent cane, which is cultivated in Barbados on a larger scale than any other cane, and may therefore be regarded as the standard for comparison. occupies a middle place with a yield of 2·41 tons per acre. In the red soil B. 208 takes first place with 3·34 tons per acre, followed closely by B. 156 with 3·32 tons and B. 147 with 3·31 tons, the lowest being B. 347 with 2·17 tons and B. 254 with 2·14 tons.

The mean results for both soils indicate B. 147 to be the best all-round cane, its yield being 27·52 tons of canes per acre, 3·1 tons of sugar and 6291 lbs. of saccharose, B. 208 occupying second place with respectively 22·55 tons, 3·02 tons, and 5443 lbs., compared with the standard White Transparent results of 20·49 tons, 2·41 tons, and 4528 lbs. A further table gives the results obtained on the three estates of "Dodds," "Pine" and "Waterford" with B. 147 and the White Transparent varieties, the means for the three estates giving B. 147 a yield per acre of 6999 lbs. of saccharose and 3·70 tons of sugar, while the White Transparent yielded 4527 lbs. of saccharose and 2·41 tons of sugar. It will thus be seen that the new seedling, B. 147, is better than the standard by more than a ton of sugar per acre. Looking to the individual and general results, the investigators consider there is a satisfactory degree of agreement under a considerable variety of conditions of culture and growth. B. 147 is regarded as the best all round seedling variety as a plant cane in Barbados, B. 208 giving promise of proving a good red soil plant and ratoon cane. Planters are advised to try, on a small scale, three or four of the varieties which have done best in these experiments, so as to be able to secure eventually the cane best suited to the nature of their particular fields and their own methods of cultivation—features which have, in their way, quite as much weight as the character of the cane itself. While B. 147 seems to be the most suitable cane for particular soils in Barbados, D. 95 appears to be the best for the different circumstances of Antigua. A private letter from Barbados, in which reference is made to the above experiments, states that the officials of the Agricultural Department seem determined on securing improved varie es o
that will suit each district, and will yield at least 50 per cent. more sugar than those hitherto cultivated.

TECHNICAL EDUCATION IN MANCHESTER.

IN no English city is a more sensible or more thorough provision for technical education to be found than in Manchester. Whatever standard of comparison is adopted, be it the number of students under instruction in proportion to the population, the amount of annual expenditure, the number of the schools, or the enthusiasm of its administrators and teachers, Manchester will take one of the foremost places in the educational ranks of the country. In some particulars, indeed, Manchester stands almost alone. In the arrangements which the Technical Instruction Committee of its City Council and its School Board jointly have made to secure the co-ordination of all educational efforts within their borders, and so avoid that over-lapping which is such a prolific source of loss and disappointment in many other districts, this centre of the great cotton industry may well serve as an example of a community where the first object of public men is to secure educational efficiency and not to assist the glorification of a particular board or committee.

This success is largely to be attributed to the recognition of the fact that any successful system of technical instruction must be adequately based upon a graduated supply of elementary and secondary education. It is too often imagined that technical education is independent of the work of the public elementary and the grammar schools. But in Manchester it has been for years borne in mind that it is only those youths who have received a thorough preliminary education who reap any advantage from the lectures and laboratory work of the technical school, be it never so perfectly equipped and staffed. The student of education consequently finds, when he endeavours to account for the satisfactory system of technical instruction in Manchester, that, in addition to the ordinary public elementary schools, supplying besides the three R's an elementary introduction to the principles of physics and chemistry, the School Board have provided four higher grade schools, all of them furnished with a "School of Science," and, as readers of NATURE know, the curriculum of schools of this type is eminently suitable as an introductory course for boys and girls who will later proceed to the technical school.

Adequate provision is also made for the children of a higher social status. Manchester is well provided with secondary schools. Its Grammar School and its High School for Girls both deservedly occupy high places among the public schools of the country. Manchester Grammar School, moreover, appears to have been one of the first to teach practical chemistry, for it possessed a small laboratory as long ago as 1868.

There is, too, every facility offered to bright children of the elementary schools to pass forward either to the Higher Grade School or to the Grammar School—this desirable end being secured by a sensible scheme of scholarships. By the same means a vital connection is assured, by way of the secondary schools, between the elementary schools and the Municipal Technical School and the University College.

Nor are the educational needs of youths who have begun the serious business of life neglected. All the schools, to the work of which brief reference has been made, are intended for young people who have as yet entered neither trade nor profession. But in all manufacturing districts the great mass of the workers have to complete their education by well-sustained efforts in evening classes of one kind or another. The authorities in Manchester are fully alive to this fact, and a wonderfully complete system of evening classes has grown up, in which it is interesting to note that the School Board and the Technical Instruction Committee can work together without friction and with the best results. Two sets of these classes are in vogue. First, there are the classes with which the School Board are more directly concerned—the evening continuation schools in which youngsters from twelve to sixteen years of age, who have left the public elementary school for the shop, the warehouse, or the factory, are either preparing themselves for the more advanced classes of the technical school, or are perfecting and continuing the work they did at school with a view to making themselves of greater value to their employers. Secondly, there are the evening classes of the technical school, intended for young men and women of sixteen and upwards, of which it is difficult to give an adequate idea in a few sentences. To really appreciate what is being done in such classes every winter's evening in large manufacturing districts, it is necessary to visit the schools where they are held. The determined efforts the young men and women, who, be it remembered, have generally spent a laborious day earning their daily bread, will make in order to become acquainted with the principles of science on which their work depends, or to become familiar with the canons of art they hope to apply in designing, is well calculated to inspire the hope that this country will some day take its former position in the industrial contest among the nations.

The students of the Day Technical School and Day School of Art are composed chiefly of the sons of middle class parents. In the majority of cases they do not enter seriously into the work of manufacture and distribution until after completing their studies. It is gratifying to be able to report that there are some exceptions to this rule. Some enterprising employers have made arrangements for sending certain of their employees to the technical school during the day—the employers themselves bearing the expense thereby incurred. It is much to be desired that this far-seeing policy may be more generally adopted. And there are also the scholarship-holders from the higher grade schools. Such is, in skeleton form, the system of technical education which has been gradually evolved in Manchester. The accompanying pictorial representation gives a bird's eye view of the whole arrangement. The illustration, which was prepared by Mr. J. H. Reynolds, the Director of the Manchester Technical and Art Schools, was awarded a gold medal by the International Jury of the Paris Exhibition.

Another cause of the high state of development of education in Manchester is the broad view which the Technical Instruction Committee have taken of their duties. On at least two separate occasions they have arranged for their Director, with certain members of the committee, to visit foreign countries to study other systems of technical instruction, and on another occasion they have sent him alone to visit the United States. In this way these Manchester authorities have become practically acquainted with German and American ideas of education. They have not endeavoured to follow slavishly such methods in their entirety, but have not hesitated to import notions they considered suitable for the peculiar needs of their own district.

The same committee have also taken a large part in the formation of public opinion in matters educational in Lancashire. At their instigation several conferences have been held of representatives of the numerous county boroughs in their immediate neighbourhood. Resolutions have been adopted and widely circulated urging the need of legislation to ensure that secondary (including technical) education shall be placed under the control of municipal councils, though the desirability of co-opting upon the Educational Committee an effective minority of persons of special experience in all grades of instruction, as well as of encouraging the joint action between the authorities of county boroughs and that of the administrative county have been recognised. But, if they would consider this question more from the national point of view, this enterprising local authority for education might come to a different conclusion. What is the state of affairs in south-east Lancashire? For the sake of example let Manchester be taken as a centre, and consider chiefly the technical education of the district. In this central city there will shortly be, in full working order, a technical school, erected and equipped at a cost of upwards of a quarter of a million, and really provided with accommodation enough for all the advanced technical students which the whole area under consideration could provide. Yet, within easy walking distance, there is the Salford Royal Technical Institute, also admirably organised and generously staffed, and this simply because Salford happens to be a separate borough. The other boroughs of this same area are, moreover, very close together. Stockport, with its own technical school, is within about five miles, and has a splendid train service connecting it with Manchester. Bury, Bolton, Oldham, Rochdale, and other boroughs are sufficiently near for their advanced students to be drafted to Manchester for instruction—the railway fares could easily be provided by means of scholarships. It would certainly seem as though, in the best interests of technical education, an area much larger than that of a county borough is desirable. With boroughs so near as they are in south-east Lancashire there is bound to be duplication and re-duplication of buildings and appliances. To have a school, like the new technical school at Manchester will be, engaged in elementary work, which could be done equally well at much less cost elsewhere, is to lose a grand opportunity of providing one centre at least for advanced technical instruction, of which the country stands in growing need. Experience shows, too, that the same staff cannot successfully undertake to teach crowds of elementary pupils and

also really be of assistance to the comparatively few picked students who will well repay any opportunities placed in their path for advanced study and subsequent research in applied science.

That there is no difficulty in getting students to travel, as has been suggested, is borne out by an appendix to the last report of the Manchester Committee for Technical Instruction. It is there set forth that last year there were, among the 4313 students of the technical school, no fewer than 2266 students from out-districts, of whom 18 came from Bolton, 25 from Bury, 44 from Oldham and Hollinwood, 16 from Rochdale, 348 from Salford, and 43 from Stockport, to name only a few towns from a long list in the report before us.

It is not recognised sufficiently that the technical education this country stands in need of is not elementary instruction in pure science. It has been demonstrated again and again in these columns that such teaching is really a part of every reasonable system of secondary education. When this is fully understood, the large classes in elementary science subjects will disappear from our technical schools. In their place we shall have students at work who, before entering the technical school, have become familiar with the broad principles of physical and chemical science, and who are now in a position to turn their attention to technical science—the application of pure science to the industry with which the student is connected.

Such a policy as has been indicated would make another desirable development possible. A specialisation of function on the part of schools in different towns could then be encouraged where necessary. Given a thoroughly representative authority for a sufficiently large area, and the apparent necessity of a class in every conceivable subject for each borough disappears. Each important technical school will be able to bend its efforts to solving the question of the proper form of technical instruction for one particular industry, or part of an industry. And Manchester, with the large number of great towns in its immediate neighbourhood, is an ideal district in which to begin some such sensible and economical supply of technical education. By all means let us have a generous supply of elementary evening classes in every town, but do let it be borne in mind that this work should only be regarded as preparatory. The serious need is for more centres where advanced students are looked after.

In conclusion, another instance of the enterprise of the Manchester Committee must be mentioned. At the instigation of their Director they have secured for exhibition in Manchester the fine educational collection which the American Government sent to the Paris International Exhibition. Invitations to teachers and others interested in education to come and examine this unique collection of objects are being sent far and wide. It cannot but have a good effect to show English educationists some of the ways in which America is in advance of us in this matter of training intelligent workmen.

A. T. SIMMONS.

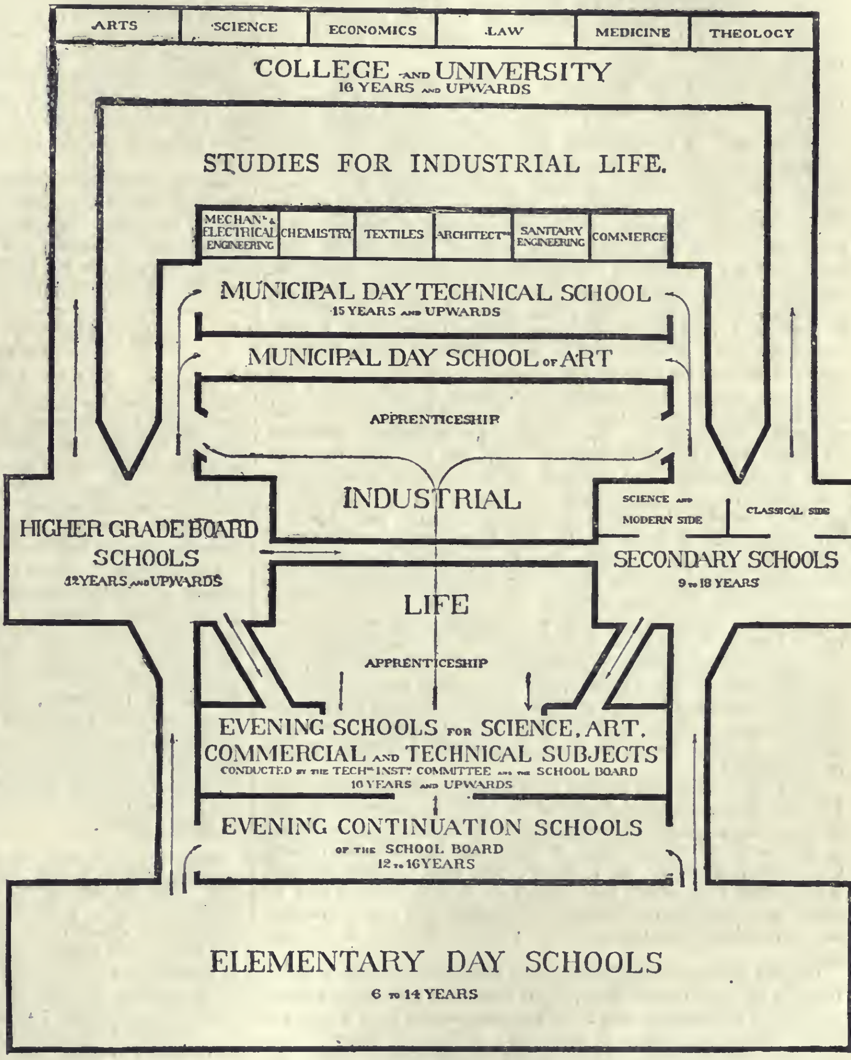

DIAGRAM ILLUSTRATING THE CORRELATION OF EDUCATION IN THE CITY OF MANCHESTER.

METHODS OF FORMATION OF HAIL.[1]

THERE are many reasons for believing that hailstones are formed in the free atmosphere by some one of several different processes, each of which may be in accord with the laws of thermodynamics:—

(1) An ascending mass of air may be so dry that it does not cool to the dew-point until far below the freezing temperature, in which case the deposit is either fine spiculæ of ice or aggregations of these into small snowflakes.

(2) If the dew-point is a little higher than the preceding, the cloudy condensation may occur at temperatures just above the freezing point, and the watery particles may be carried up a little higher and frozen into what is called frozen fog. These same particles, when driven by the wind against an object, accumulate on it as frostwork.

(3) When a rising mass of air forms a large cumulus cloud at a low level, having a rapidly ascending current in its interior,

[1] Abridged from a contribution by Prof. Cleveland Abbe to the U.S. *Monthly Weather Review*.

the latter, by its buoyancy, will rise much higher than if there were no cumulus cloud; it may pass upward into the so-called hail region, where water drops and ice particles may coexist, and still higher up into the region where only ice and snow can exist.

(4) Raindrops falling from relatively warm clouds through a very cold stratum of air below may be frozen into sleet before they reach the ground.

To these four elementary methods of forming atmospheric ice we have to add the mechanical processes by which the small particles accumulate as large hailstones. Undoubtedly much light was thrown upon this subject by the notes made by observers on Pikes Peak during the early years of the occupation of that station.

In the thermodynamic studies of Hertz and von Bezold is employed the expression "the hail stage," viz. that stage in which the temperature of 32° prevails in an ascending mass of moist air. It is supposed that the ascending air, having already cooled to the dew-point, is carrying up with it a quantity of water, either in small cloud particles or in large raindrops. When these have ascended to the level where the rising moist air is cooled to the temperature of freezing, they continue to give up to the air a little of their specific heat until they are themselves frozen into hail or sleet. There is, therefore, a thin layer of air in which this process of freezing is going on and where the rising mass of mixed air and rain is kept at a uniform temperature until all the water is converted into ice. This is spoken of by Hertz as the hail stage; below it is the rain stage and above it is the snow stage. In this latter region the ascending air, being already cooled below the freezing point, can deposit its moisture only as snow or small crystals of ice. Now the actual hailstones observed on Pikes Peak are so frequently composed of snow that has been partly melted and refrozen, or mixed with water drops and refrozen, that we cannot suppose them to have been wholly formed within the thin layer known as the Hertzian hail stage. It is more likely that they are formed partly within that and partly within the Hertzian snow stage. The memoir of Hertz assumes throughout that the changes of temperature within the ascending air are strictly adiabatic. This requires that the ascent be so slow that the drops of water carried upward maintain the same temperature as the surrounding air. But these two conditions are almost physically incompatible; it is probable that neither of them are ever realised in nature. Among other combinations that are possible and may help to explain the great variety of forms of hailstones that are caught upon the summit of Pikes Peak, we may suggest the following as the most common:—

(1) Frozen raindrops carried very rapidly upward through the Hertzian hail stage may continue on into the snow stage and grow by the accretion of snowflakes until they are finally dropped to the earth, in which latter process they continue increasing their snowy covering. If, however, they pass through the hail stage before they reach the ground in their fall, they will be found to consist of an icy nucleus surrounded by a snowy envelope and covered over all by a layer of a frozen mixture of ice and snow.

(2) Air that has ascended into the snowy stage without going through the rain or hail stage, or, at least, to a very slight extent, because of its dryness, may form large snowballs high above the Peak before beginning to fall. As such balls descend very rapidly, the interior retains a low temperature, while the exterior is slightly warmed and melted by the action of the warmer air that the snowballs find near the ground. The result is large hailstones, consisting each of a thin layer or crust of ice and a snowy mass within.

(3) In the formation of snow and hail in the midst of ascending currents of air, we must expect to notice the same phenomenon as in the formation of rain, viz. after the first condensations have taken place upon dust and foreign substances the rising mass of cloud represents dustless air in the presence of water particles, but cooled by expansion to such an extent that the air between the drops, or the ice spiculæ, is in a state of supersaturation. When this condition has become too intense, large quantities of aqueous vapour suddenly condense, rushing together into large drops of rain or large masses of snow, and carrying with them all the finer particles within their respective spheres. At the very low temperatures at which this occurs, water will hold considerable air in solution, and additional air is also included at the centre of the snowball among the particles of snow and ice. Such large snowballs are heavy enough to descend rapidly from the snowy stage, through the rain and hail stages to the ground, and in so doing they become saturated with water which recrystallises forming solid hailstones, but at the centre of the mass they still hold, confined, the air originally included in the snowball, and this is compressed under several atmospheres, as was shown in 1869, by P. Reinsch (see *Pogg. Ann.*, 1871, or *Phil. Mag.*, 1871, vol. xlii. p. 79), who observed that when such hailstones are melted under water the little bubble of air at the centre is seen to suddenly escape and expand sufficiently to demonstrate the existence of a pressure of fifty atmospheres under which it was confined. In this formation of snowballs and the resulting hail from supersaturated air within the snow stage there is an electric disturbance entirely analogous to that which takes place when great drops of rain are formed within the rain stage. In both cases violent thunder and lightning are observed just before the fall of the hail or the rain.

These and other hypotheses that might be framed relative to the methods of formation of the various kinds of hailstones must, however, only be regarded as suggestions intended to stimulate experimental and theoretical research in this direction. One cannot doubt but that the history of the formation of hail is written in its structure if we could but interpret it.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—Prof. W. J. Sollas has been elected to a fellowship at University College. This fellowship, however, is not to be regarded as attached to the professorship of geology; the election concerns the present professor only, the College being under no obligation to his successor.

Prof. Townsend, the new Wykeham professor of physics, has come into residence, but the space intended for his laboratory will not be available until the Radcliffe Library has been transferred to its new building.

CAMBRIDGE.—The Clerk-Maxwell studentship in physics, tenable at the Cavendish Laboratory, has been awarded to Mr. H. A. Wilson, Trinity. Mr. P. V. Bevan has been appointed assistant demonstrator in physics, in succession to Prof. Townsend. Mr. J. C. M. Garnett has gained the Sheepshanks astronomical exhibition at Trinity College. Mr. L. Whibley, Fellow of Pembroke, has been appointed assistant to the secretary of the University Press Syndicate. Mr. Yule Oldham, Reader in geography, is lecturing this term on the hydrosphere, and on the geography of Central Europe. A grant of 50*l.* for the current year has been made to the Department of Pathology, towards the course of instruction in bacteriology for the diploma in public health.

THE Report of the U.S. Commission of Education for the year 1898–99 has been received. It is a volume of thirteen hundred pages, containing papers and statistics on many branches of educational activity in various countries. Among the subjects of papers of interest in connection with instruction in sciences are school gardens, by Herr E. Gang; the teaching of geography, by Dr. A. J. Herbertson and others; manual training in Germany; minor mental abnormalities in children as occasioned by certain erroneous school methods; and an annotated chronological list of American text-books on arithmetic, prepared by Drs. J. M. Greenwood and A. Martin.

SCIENTIFIC SERIALS.

Symons's Monthly Meteorological Magazine, January.—Heavy rainfall of December 30, 1900. The official weather charts showed that the centre of a barometric depression lay over the middle of Ireland in the morning of that day, and that it moved southeastwards, passing Bristol in the early evening, and reaching the English Channel on the morning of the 31st. This storm was remarkable for the heavy rains which fell in the valley of the Severn and its tributaries. Falls exceeding two inches in 24 hours occurred over a broad diagonal belt from the mouth of the Severn to the mouth of the Humber, while amounts exceeding three inches occurred in a narrow strip running for about 85 miles in a northeast direction from near Bristol and Chepstow, covering an area of nearly 1000 miles.—The mild December. The mean temperature for the month in the north-

west of London was 6°·2 above the average for 40 years, and the mean maximum and mean minimum exceeded the average by about the same amount. The month ranks with the mildest of the last half century, but was equalled by December 1898, and exceeded by December 1868. The number of days (19) on which the temperature exceeded 50° is unprecedented in this series of observations, for there were only 18 such days in 1868 and 17 in 1898. The present number of this popular magazine completes the 35th volume. The magazine, while retaining its special interest in rainfall, will in future deal more fully with all branches of meteorological science than it has done in the past.

Bollettino della Società Sismologica Italiana, vol. vi. No. 5.—Seismic Greece, by F. de Montessus de Ballore. A study of the geographical distribution of earthquakes in Greece.—On the velocity of the earth-waves of the Roumanian earthquake of September 10, 1893, by C. Davison (in English). Good observations of the time were obtained at Bucharest and Oxford, the latter by Prof. Boys in his experiment on the Newtonian constant of gravitation. They give a mean surface-velocity of 3·98 km. per second.—Three-component seismometrograph for strong earthquakes, by G. Agamennone. A first sketch of a proposed instrument.—Seismometrograph with continuous-velocity registration, by A. Cancani.—Notices of earthquakes recorded in Italy (August 4 to 24, 1899), by A. Cancani, the most important being distant earthquakes on August 17 and 24.

SOCIETIES AND ACADEMIES.

LONDON.

Chemical Society, January 17.—Prof. Thorpe, President, in the chair.—The following papers were read:—The preparation of iodic acid, by A. Scott and W. Arbuckle. The authors prepare iodic acid by heating powdered iodine with nitric acid in a glass flask fitted with a ground-in reflux condenser and a tube by means of which oxygen is passed through the boiling liquid.—Note on isomeric change and meta-substitution in benzenoid amines, by A. Lapworth. The author explains the action of fuming sulphuric acid on dimethylaniline by means of an extension of his previously published views on the occurrence of isomeric change.—The preparation of esters from other esters of the same acid, by T. S. Patterson and C. Dickinson. It is shown that ethyl tartrate can be converted into methyl tartrate by the action of methyl alcohol and hydrogen chloride, and that methyl tartrate can be converted into ethyl tartrate by an analogous process.—Tecomin, a colouring matter derived from *Bignonia tecoma*, by T. H. Lee. The wood of *Bignonia tecoma* yields a yellow crystalline colouring matter, and is used locally as a dye for cotton and as a stain for wood.—A new method for the measurement of ionic velocities in aqueous solution, by B. D. Steele. The method consists in enclosing the liquid to be examined between two partitions of gelatine which contains the indicator ion in solution. On the passage of the current the cation of the solution is followed by the cation of the indicator, and the anion of the solution by the corresponding anion of the indicator. It is necessary in all cases that these indicator ions should move more slowly than the ion to be measured; the motion is followed by means of a cathetometer.—Metal-ammonia compounds in aqueous solution, Part ii. The absorptive powers of dilute solutions of salts of the alkali metals, by H. M. Dawson and J. McCrae.—The amide, anilide and toluidides (ortho- and para-) of glyceric acid, by P. F. Frankland, F. M. Wharton and H. Aston.

MANCHESTER.

Literary and Philosophical Society, January 22.—Prof. Horace Lamb, F.R.S., President, in the chair.—The President referred to the loss sustained by the Society through the death of Prof. Ch. Hermite, one of its honorary members.—Mr. Francis Jones showed the mode of detecting small quantities of arsenic by Marsh's, Reinsch's and Gutzeit's methods. He also showed the results obtained by the action of light on the hydrides of arsenic and antimony in contact with sulphur, constituting a further test of the presence of these metals. The result obtained from a glass of arsenical beer by Marsh's test was also exhibited, together with a sample of invert-sugar containing arsenic.—Mr. R. L. Taylor remarked upon the occurrence of arsenic in certain green tapers, of which he showed two varieties obtained from half-a-dozen samples purchased in the neighbourhood of Manchester, and demonstrated the presence of a marked quantity of arsenic in a short piece cut off from one of these tapers.—Dr. C. H. Lees mentioned a very compact formula for the circumference of an ellipse due to Mr. Thomas Muir, which is readily calculated with the aid of Barlow's tables. The accuracy of the approximation is very marked.

EDINBURGH.

Royal Society, January 7.—Prof. Copeland in the chair.—Mr. W. S. Bruce, in a paper on exploration in Spitsbergen and soundings in seas adjacent, gave an account of the work he had undertaken in conjunction with the Prince of Monaco in the yacht *Princess Alice*, and with Mr. Andrew Coats, of Paisley, in the yacht *Blencartha* (now *Pandora*). One main object of the *Blencartha* expedition of 1898 was the determination of salinities and temperatures in the Barentz Sea, an important result being the delineation of the isotherms in the successive summer months. In the expedition of 1899, the Prince of Monaco's chief aim was to survey the littoral regions to the north and north-west of Spitsbergen. The most detailed work was done in Red Bay, which they found to be very inaccurately described in the Admiralty map, and in which they had taken over 2000 soundings and 2700 angles. Many new peaks and glaciers were discovered and named, one to the south of the bay being named Peak Ben Nevis. The greatest depths in the bay were much greater than the depths in the open sea beyond, a fact which seemed to prove the glacier origin of the bay. The paper was fully illustrated by a number of lantern slides, which brought out clearly much of the geological and zoological character of Spitsbergen and Novaya Zembla.

PARIS.

Academy of Sciences, January 21.—M. Fouqué in the chair.—Notice on M. Ch. Hermite, by M. C. Jordan.—Notice on M. Adolph Chatin, by M. Gaston Bonnier.—Influence of the substitution of alcohol for sugar in food, in isodynamic quantity, on the value of the muscular work accomplished by the subject, by M. A. Chauveau. The experimental results obtained during a period of 389 days show that the partial substitution of alcohol for sugar in the food ration in a subject doing work has an unfavourable effect from all points of view, there being a diminution in the absolute value of the muscular work, and an increase in the food used up with respect to the work accomplished.—On the influence of climate upon the evolution of experimental pleuro-pulmonary tuberculosis, by MM. Lannelongue, Achard and Gaillard. Three hundred guinea-pigs were inoculated with human tuberculosis, and then submitted to varying climatic conditions, some remaining in the laboratory at Paris, others being taken to the sea, open country, mountains, &c. The advantage appeared to be with those remaining in the laboratory. Although in each lot all the animals were inoculated with the same virus on the same day, great differences occurred in the development of tuberculosis.—On the supplementary condition in hydrodynamics, by M. P. Duhem.—M. Mascart announced to the Academy the death of M. Gramme.—On the telescopic planets, by M. R. du Ligondès. An analysis of the distribution in space of the telescopic planets shows that the assumption that they represent the *débris* of a nearly flat circular ring does not explain all the facts. The more probable hypothesis would appear to be the generation of the planets by successive agglomerations of matter circulating in the interior of the solar nebula.—On the generalisation of a theorem of M. Picard, by M. S. Kantor.—On a theorem in the calculus of probabilities, by M. A. Liapounoff.—On the liquefaction of gaseous mixtures. Variation of the concentrations of the two co-existent liquid and vapour phases along the isotherms, by M. F. Caubet. It is shown that any mixture of CO_2 and SO_2 which, at 66°·3 and under a pressure of 57·6 atmospheres, can give two co-existing phases, will give a liquid phase of concentration 0·70926, and a vapour phase of concentration 0·33238.—On some properties of sodium peroxide, by M. de Forcrand. The author points out that the method of preparation of hydrated sodium peroxide, given by M. Jaubert in a recent number of the *Comptes rendus*, is identical with that published by Prof. Vernon Harcourt forty years ago.—On the combinations of ammonia with aluminium chloride, by M. E. Baud. The author's results differ from those previously obtained by Persoz and Rose. At least four stable compounds exist, $Al_2Cl_6.2NH_3$, $Al_2Cl_6.10NH_3$, $Al_2Cl_6.12NH_3$, and $Al_2Cl_6.18NH_3$. The first of these distils without decomposition at 450° C.—On the isolation of yttria, ytterbium, and the new erbium, by MM. G. and E.

Urbain. The crude earths from gadolinite are converted into ethyl sulphates. After ten crystallisations the mother liquors contain only the three elements yttrium, erbium and ytterbium, with perhaps a trace of thorium. These were further separated by the fractional decomposition of the nitrates by heat, which, in the absence of earths of the gadolinium group, gives a very satisfactory separation.—On an arsenide and chloro-arsenide of tungsten, by M. Ed. Defacqz. The interaction between hydrogen arsenide and tungsten hexachloride is analogous to that with the corresponding phosphorus compound, two compounds of the composition WAs_2 and W_2AsCl_6 being isolated.—On nitrofurfurane, by M. R. Marquis. By allowing anhydrous nitric acid and furfurane in acetic anhydride solution to react at $-5°$ C., a nitrofurfurane can be obtained. The exact position of the nitro-group is not yet determined.—The absorption spectra of the indophenols, by M. Paul Lemoult.—On some new organometallic compounds of mercury, by MM. Auguste Lumière, Louis Lumière, and Chevrotier. When alkali phenol disulphonates react with mercuric oxide, compounds are formed of great solubility, and presenting some peculiar reactions, not being precipitated by soda, hydrochloric acid, or ammonium sulphide. Their taste is purely saline, and not metallic as is usual with mercury salts. The solutions, however, possess great antiseptic power.—On the mechanism of diastatic reactions, by M. M. Hanriot. By studies on the ferment lipase it is shown that the ferment, when attenuated by a chemical action, may regain its original activity, and also that the action of lipase upon acids and ethers appears to be a chemical combination governed by the ordinary laws of dissociation.—On the plurality of the chlorophyllines and on the metachlorophyllines, by M. M. Tsvett.—On a pseudo-agaric acid, by MM. Adrian and Trillat. The body extracted from agaric by alcohol does not appear to be a true acid, and when pure is without special physiological properties.—Transformation of creatine into creatinine by a soluble dehydrating ferment in the organism, by M. E. Gérard.—Modes of formation and preparation of propylbenzene, by M. F. Bodroux. Normal propylbenzene is formed along with other products by the interaction of benzene, trimethylene bromide and aluminium chloride.—Filtration of air by the soil, by M. Auguste Gérardin.—On the *rôle* of the chlorophyllian function in the evolution of terpenic compounds, by M. Eug. Charabot. Any influences which increase the vigour of the chlorophyll function in plants also appears to favour the production of the ethers of terpene alcohols.—On the chemical composition of the coffee from Grande Comore, by M. Gabriel Bertrand.—Action of mucus upon the organism, by M.M. Charrin and Moussu. Fresh mucus possesses poisonous properties when injected into the blood.—Radiopelvigraphy and radiopelvimetry at long range, by M. Henri Varnier.—The sponges of the Belgian Antarctic expedition, and the bipolarity of the fauna, by M. E. Topsent.—Origin of the pigment in Tunicates. The transmission of the maternal pigment to the embryo, by M. Antoine Pizon.—A new theory of chromatic adaptation, by M. Georges Bohn.—Researches on the structure of some of the lower fungi, by M. Guilliermond.—Apparent symmetry in crystals, by M. Fréd. Wallerant.—On the origin of the gold in Madagascar, by M. A. Lacroix.—On the age of the eruptive rocks of Cape Aggio, by M. Leon Bertrand.—The dômes of Saint Cyprien (Dordogne), Sauveterre and Fumel (Lot-et-Garonne), by M. Ph. Glangeaud.

DIARY OF SOCIETIES.

MONDAY, FEBRUARY 4.

VICTORIA INSTITUTE, at 4.30.—Ancient Script in Australia: E. J. Statham.

TUESDAY, FEBRUARY 5.

ROYAL INSTITUTION, at 3.—Practical Mechanics: Prof. J. A. Ewing.

ZOOLOGICAL SOCIETY, at 8.30.—On the Mammals of the Balearic Islands: Oldfield Thomas.—On the Structure of the Horny Excrescence known as the "Bonnet" of the Southern Right Whale (*Balaena australis*): Dr. W. G. Ridewood.—A List of the Batrachians and Reptiles obtained by Dr. Donaldson Smith in Somaliland in 1899: G. A. Boulenger, F.R.S.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Present Condition and Prospects of the Panama Canal Works: J. T. Ford.

WEDNESDAY, FEBRUARY 6.

ROYAL INSTITUTION, at 3.—Government and People of China: Prof. R. N. Douglas.

GEOLOGICAL SOCIETY, at 8.—On the Origin of the Dunmail Raise (Lake District): D. Oldham.—On the Structure and Affinities of the Rhætic Plant *Naiadita*: Miss Igerna B. J. Sollas.

THURSDAY, FEBRUARY 7.

ROYAL SOCIETY, at 4.30.—*Probable papers*: The Boiling Point of Liquid Hydrogen, determined by Hydrogen and Helium Gas Thermometers: Prof. Dewar, F.R.S.—On the Brightness of the Corona of January 22, 1898. A NEO-DARWINIAN ON EVOLUTION.

Problems of Evolution. By F. W. Headley. Pp. xvi+373. (London: Duckworth and Co., 1900.)

MUCH of the work that has lately appeared on the subject of organic evolution has been characterised, if not by a misapprehension of the main points at issue, at any rate by a want of due proportion in the treatment of data, and by a tendency to build an elaborate superstructure on a very slender foundation of fact. This applies less to the work of English authors than to those of other countries. It is satisfactory to find that English men of science, who have always taken a leading part in the promotion of sound and rational views on the methods of evolution, are still distinguished by the thoroughness and good sense which they bring to bear on the discussion of evolutionary problems.

Mr. Headley's book is on the whole a favourable example of this kind of literature. It is true that his statements of fact are not always free from error, nor are his arguments on all points convincing; he shows, nevertheless, a just appreciation of the difficulties of the subject and a wide acquaintance with the various attempts that have been made towards their solution, while his own suggestions have been well considered, and are often of distinct value. His standpoint is more thoroughly Darwinian than that of many other recent writers, and in him the principle of natural selection as the most important factor in evolution finds a powerful and skilful advocate. He is an uncompromising opponent of Lamarckism, and one of the most satisfactory sections of the book is that in which he shows how completely the Lamarckian principle fails to account for those very phenomena which have been most confidently appealed to in its support. This, however, does not preclude him from recognising the importance of the suggestion made independently by Profs. Mark Baldwin and Lloyd Morgan, viz., that the selection value imparted to a congenital variation by exercise may enable such variation to become the starting-point for other variations in the same direction (Darwin's "Continuity of Variation"). Not only does he adopt the principle in the form here stated, but he goes on to show that parental care and the gregarious habit may act in a similar way by promoting the survival of certain characters which can be increased by practice, and so giving an opportunity for their enhancement, by further variation, in successive generations. But he rightly points out that this cannot properly be claimed by Lamarckians as a concession to their views; those who would so claim it must have, as he says, "a singular power of mistaking an utter rout for a compromise." For, as Prof. Lloyd Morgan makes clear, there is here "no transmission of modifications due to individual plasticity"; and what really emerges is that natural selection is capable, without such transmission, of doing all that was exclusively claimed on behalf of Lamarckism.

On the defensive side, Mr. Headley makes a forcible use of the phenomena of adaptation. He has little to bring forward that is actually new on this head, but his statement of the case is a clear and cogent one. The principle of recognition marks is acknowledged by him as supplying the key to many instances of apparently useless characters, and this line of argument might profitably have been expanded. He is on strong ground when asserting the importance of slight points of difference.

"Two races are brave beyond dispute, but one will stand a little longer under fire than the other, and it is this little that makes all the difference in the struggle. Two young men are about on a par, and seem likely to run neck and neck in the race of life, but an almost imperceptible superiority in one seems to act with cumulative effect, and in twenty years, say, he is miles ahead."

The latter illustration will appeal to most readers with experience of life.

The author's treatment of the important subject of variation is interesting and suggestive. True to his anti-Lamarckian principles, he denies any direct influence of the environment on the origin of variations properly so-called: "An external condition can do nothing but bring to light some quality" already latent. To explain the variations among offspring we must fall back on the doctrine of the continuity of the germ-plasm coupled with the specialising effect of cell-division.

"When fission takes place, inequality must result. . . . There is a thorough shuffling of the cards before they are cut."

This view is to some extent akin to Weismann's earlier position as to the import of reducing divisions and amphimixis. But the author goes further than Weismann. Not only have the reducing divisions of the germ-cells in the metazoa the value of an incipient specialisation, but the simple fissions of the protozoa have precisely the same significance. Over-specialisation, such as would in many cases result from a process of fission indefinitely continued, is a cause of failure and death. This in the bulk of the protozoa, at all events, is counteracted by periodical conjugation, which tends to restore to each cell some elements which it had lost, or was in process of losing, by repeated fission. Amphimixis in the metazoa has a similar *rôle*. Hence both fission and conjugation, or amphimixis, are a cause of variation, though the latter, while increasing the possibilities of deviation, tends to prevent it from taking a harmful direction. An obvious criticism on this view is that two imperfect organisms do not necessarily make a perfect one. The speculation, nevertheless, is ingenious and interesting, even though it may fail to convince.

In a further discussion of that perfection of adaptation which almost appears to call for a "directive force" presiding over variation, he takes occasion to give an account of Prof. Weldon's application of the law of chance. The argument is fairly stated, but in his comments upon it Mr. Headley seems disposed to blame Prof. Weldon's results for not clearing up points with which they were never intended to deal. His criticism is thus somewhat beside the mark, for, as he himself admits, Prof. Weldon's aim was chiefly to demonstrate the high probability of advantageous variations affecting a large number of individuals at the same time, in this way affording abundant material for selection. The question why variation should take one direction more than another belongs to

a distinct line of inquiry. In framing his own answer to the question, the author lays stress on the controlling power of heredity, on Darwin's principle of "continuity of variation," or, as he prefers to call it, "sequence of variation," and also on the fact that the variations of the organic environment of a species—the several other species, that is to say, with which it has to keep *en rapport*—being subject to similar limitations with its own, are not likely to set it an impossible task in the way of providing fresh adaptations. Moreover, there are usually periods in the history of a species when it has, as it were, a choice of environments, so that the possibilities of adaptation open to it are enlarged. This latter position might well have been illustrated by the striking case of certain mimetic butterflies; amongst which it is often found that species closely allied to one another, and sometimes even the two sexes of the same species, have been drawn apart, so to speak, into separate protected colour-groups; while still other species of the same affinities occupy intermediate positions, ready, as it were, to throw in their lot with this or that colour-combination, according to their needs. The upshot of the author's contention as to variation and adaptation is, that while the range of possible variation is not indefinite, but necessarily limited, the limitation is in no sense due to the direct action of the environment; still it is this very limitation that renders adaptation possible, by ensuring a supply of such material as is capable of being moulded by the selective action of the existing external conditions. Variation that took place merely at random, were it conceivable, would almost inevitably consist of all misses and no hits.

In the second and concluding part of the book, Mr. Headley deals with the application of evolutionary doctrine to the problems of human development. His treatment of this part of the subject, as of the other, shows freshness, vigour and ability; but he could here hardly avoid raising points of a highly controversial character, and most of his conclusions are likely to be sharply assailed. Adopting in many respects the point of view of Mr. Benjamin Kidd, he discusses at length the origin and influence of the moral sense, and the various conditions that with advancing civilisation tend to defeat or delay the operation of natural selection. The antagonism between altruism and the "cosmic process," which was adumbrated by Huxley in his memorable Romanes lecture, receives a careful and extended treatment; and the author states his own conclusion somewhat as follows:—The development of human intelligence has in many ways checked the wholesome operation of natural laws. Being capable of exercise in anti-social directions, it has in times past threatened the well-being if not the very existence of the race. From this fate humanity has so far been preserved by the practice of altruism under the sanctions of religion and morality. Supposing this first peril to have been successfully met, there remains the further danger of physical degeneration, which may presently become imminent, and the proper treatment of which is among the most important problems that await us. In spite of his indictment of human reason, Mr. Headley is no pessimist. So far from having lost confidence in the future of the race, he looks boldly to the old sanctions, under higher and more enlightened forms of application, to save the human species from physical, as they already have from social disintegration. It is obvious that the working out of this idea, which indeed is not attempted by the author himself in any detail, involves considerations which are unsuitable for discussion in a notice like the present. Suffice it to say that Mr. Headley does not write at random; and that his views challenge attention, whether sympathetic or otherwise.

Notwithstanding an occasional abruptness and jerkiness of style, the author writes well and expresses his views with clearness. More care might with advantage have been bestowed on the proofs; misprints are not uncommon, the punctuation frequently leaves much to be desired, and there is a curious lack of uniformity in the use of scientific names. Some questionable palæontology will be found on p. 105, and some equally doubtful pathology on pp. 246, 247. An inaccurate use of the term "chrysalis" may be noted on p. 59. But in spite of these and other failings the book reaches a high standard of merit, and should appeal to a wide circle of general readers besides those more especially conversant with the subjects of which it treats. F. A. D.

THE CENTURY OF SCIENTIFIC PROGRESS.

The Story of Nineteenth Century Science. By Henry Smith Williams, M.D. Pp. x + 476. Illustrated. (London and New York: Harper and Brothers, 1900.) Price 9*s*.

THE story is worth telling, for whatever the ages may hold in store they can hardly deprive the nineteenth century of the distinction of having witnessed a progress in science without a parallel in the earth's history. Each step in advance has served as a starting-point for many others, and the record of the last quarter century, even of the last decade, far surpasses that of the corresponding period at the outset. The opening chapter of this book, "Science at the Beginning of this Century," enables us to realise how immense the gain has been.

To write such a history is a task on which, at the beginning of the century, an author might have entered with a light heart. Now such an undertaking seems almost an audacity. Scientific omniscience has long become impossible; but in an age of such rapid progress something of the kind is required for a work like this. The reviewer is in a still worse plight. How can he—probably almost wholly occupied in trying to carry some one road a little farther into the unknown land—be competent to decide whether the author has done full justice to those similarly engaged in other directions? So I shall speak critically only of my particular subject, and for the rest briefly touch upon the salient features in the author's narrative. The book, I may remark, evidently had its origin on the other side of the Atlantic, so that the illustrations have a slightly American tinge. The same also may sometimes be said of the English. As example, "down" is a new verb to us; "per hypothesis" jars on the ear; to say that a man was "then only a novitiate in science," startles any one accustomed to employ the word novice. Such solecisms, however, are but few. The chapter on palæontology seems oddly placed between

those on astronomy and geology—surely this, as regards the latter, is a "cart before horse" position. It is also widely separated from biology, with which it is no less closely connected.

We turn, then, to geology, which a century ago could hardly claim to be a science. We find a clear sketch of the principal advances, with some particulars about those who made them, and only in a very few cases are we inclined to dissent. To say that the "strata are level" in the mountains of Sicily [and] the Scotch Highlands is doubtful, unless we are rather liberal in using the term mountain, and is true of only a small portion of the latter region. In speaking of the joint work of Murchison and Sedgwick, the author fails to mention the Cambrian system, and thus does an injustice to the man who independently and accurately established its position. In regard to the Laurentian system, we think that the statement "they are now more generally regarded as once-stratified deposits metamorphosed by the action of heat" would have been truer twenty years ago than at the present time, for the majority of these rocks, we think, are now more commonly considered to have had an igneous origin. While we believe, with the author, that uniformitarian creed must not be so enunciated as to exclude a certain "slowing down," we should hesitate to assert that in any known era

"large areas were rent in twain and vast floods of lava flowed over thousands of square miles of the earth's surface, perhaps at a single jet; and, for aught we know to the contrary, gigantic mountains may have heaped up their contorted heads in cataclysms as spasmodic as even the most ardent catastrophist of the elder day of geology could have imagined."

But with a crust much thinner than it has been in later geological ages, fracture would be more easy and catastrophic disturbances less intense, because more frequent. At any rate, the facts of geology, so far as we can remember, do not support this statement, and Lord Kelvin, who is quoted in its favour, once used the simile of the last spurt of a cooling porridge pot to indicate that, owing to the greater resistance of the crust, a local catastrophe might be as severe in a late age as in an early one. Again, we demur to the following statement—if the author is speaking of any known geological age—that the constituents of the early atmosphere "have since been stored in . . . granite." Unless we admit it to have cooled on the earth's surface, how could this rock plunder the atmosphere? But *Ubi plura nitent . . . paucis offendar maculis?* The author gives a clear sketch of the progress of geology and palæontology from infancy to adult manhood. The principal stages of growth are described, even youthful escapades, the age of which is not yet ended, are sometimes chronicled. But for the most part he restricts himself to those hypotheses which have been able to stand the test of time and are now more or less promoted to the dignity of theories.

But the advances in terrestrial and celestial physics have been even more surprising. With the spectroscope to investigate and the camera to record, each being a discovery of this century, sun, stars, comets and nebulæ are yielding up their secrets; the existence of the ether, he nature of light, the relations of the physical forces, are demonstrated—nay, the genesis of worlds and of matter itself are becoming themes for discussion, while immense advances have been made in chemistry and meteorology. The same is true of the biological sciences, which have been almost revolutionised since the appearance of the "Origin of Species," little more than forty years ago. Though, as these pages prove, no one would assert that the last word has been said on evolution, the process, however it may be explained, is a fact, and its consequences have already extended far beyond biology.

The advance is not yet ended. In proof of that we need only point to the marvels of the Röntgen and Becquerel rays—discoveries of the last decade. Problems enough await solution in this century, of which an excellent summary will be found in the concluding chapter. Unless some dark catastrophes await civilisation, like that triumph of savage ignorance which boasted that "the republic has no need of *savants*," many secrets of nature should be discovered before the new century has run its course. Matter, force, energy, life—what problems these four words suggest, perhaps in part inscrutable—but still, even of these our descendants should know more than the wisest of our own age.

Dr. Williams has produced an interesting book, the more so because it is liberally illustrated with portraits of the leaders of science. These, though unpretending, are often good likenesses, the other illustrations being of a more commonplace character. This volume, like White's "Warfare of Science," should be a manual in every course of theological instruction, because the history of the progress of science declares how it has been opposed, in the imaginary interests of religion, by the friends of the latter. In the past the geologist, the biologist, the physiologist have been vituperated and denounced by ignorant champions of theology, whose fears and assertions time has proved equally unfounded. The mistakes of their forefathers will be a lesson of caution to coming generations; for the spirit of ecclesiasticism is not yet extinct, and our successors will have to confront old foes, though perhaps with new faces.

T. G. BONNEY.

VAN 'T HOFF'S PHYSICAL CHEMISTRY.

Lectures on Theoretical and Physical Chemistry. By J. H. van 't Hoff. Translated by R. A. Lehfeldt. Part iii. Relation between Properties and Composition. Pp. 143. (London: Edward Arnold, no date.)

Leçons de Chimie Physique. Par J. H. van 't Hoff. Ouvrage traduit de l'allemand par M. Corvisy. Troisième partie. Relations entre les Propriétés et la composition. Pp. ii + 170. (Paris: A. Hermann, 1900.)

THE English and French translations of the concluding part of van 't Hoff's lectures are now before us. Although this part ostensibly deals with the relations between properties and composition, its scope is really wider than its title, for it includes the discussion of colligative properties, which are not related to composition at all.

The first third of the book is chiefly concerned with volume, pressure and temperature relations as deduced from van der Waals's equation and the critical constants. As a feat of terse and lucid exposition, this section is unequalled in any text-book with which the present

writer is acquainted. The subject is not an easy one, and the reader must bring a certain concentration of thought to its study; but once he has mastered these forty odd pages he will know the bearing of the critical phenomena on physical chemistry with a thoroughness that will leave little room for addition in his subsequent reading, except on matters of detail. The work of Young, Guye, Daniel Berthelot, Mathias, Guldberg, Traube—all receives consideration, and the impression left is one of harmony and completeness, at least from the practical empirical standpoint.

Boiling-points, latent heats and specific heats are next taken up, and the student will be surprised at many a new way of looking at old familiar facts. Under the heading of surface tension, the method of Eötvös and Ramsay and Shields for determining molecular weights is fully discussed, and a theoretical connection shown with Mathias's law of the rectilinear diameter. The section on physical properties concludes with a chapter on refractive indices and dielectric constants.

The second portion of the book is entitled, Relations between Chemical Properties and Composition. Its first subdivision treats of the affinities of elements as displayed in connection with their positive or negative character. The author's views on this important general question are summarised thus: Positive or negative character is defined as the tendency to combine with positive or negative electricity. The extreme positive and negative elements, such as sodium and chlorine, show the strongest affinities, which suggests that their opposite electrical charges play an active part in their chemical combination. Intermediate elements which are neither decidedly positive nor negative, *e.g.* carbon, often show a tendency to combine with themselves which is wanting in the extreme elements. As second consequence of the tendency to combine with electricity, we have the free production of atoms charged with electricity—the ions—in solvents like water which weaken the electrical attraction owing to their high dielectric constant. This breaking up or loosening in its turn entails a facility for reaction which is absent from intermediate elements, carbon compounds, for example, being characterised by great inertness in chemical action. Lastly, the phenomena of affinity are most marked when the atomic weight is small and the atomic volume large.

A study of the affinities manifested by explosive compounds and explosive mixtures is next entered on, and then the influence of the separate elements on the properties of compounds which they enter is taken up in detail. The concluding sections are on the changes in reaction velocity caused by certain elements and groups, and the appearance of entirely new chemical properties occasioned by the conjunction of certain elements.

On looking back through the book as a whole, one notes the circumstance that Parts i. and iii. are better done than Part ii, and that, on the whole, the physical portions are perhaps at a higher level of excellence than the chemical portions. It is everywhere evident, however, that the material has been wrought into form by a powerful thinker, who sees deeper and more clearly into his subject than any of his contemporaries.

A comparison of the English and French translations shows that the former, being more literal, is more difficult to follow than the latter. The freedom of translation in the French version is, however, not attained at the expense of accuracy; indeed, in more than one passage the sense of the original is better given in the French translation than in the English. To translate *dann* by "therefore" or even by "then," when it is merely used for the purpose of enumerating points of the argument (as in p. 89 of the original, and p. 98 of the English version), gives a false impression of logical sequence; and to translate *Affinitätsäusserungen* by "indications of affinity" (same page) is scarcely exact.

To the French version are appended two notes by the translator—one on Dieterici's modification of van der Waals's equation, the other on Kanonnikoff's "real density," derived from the formula of Lorentz and Lorenz.

Whilst strongly recommending the English version to all interested in physical chemistry, the writer would express the hope that in a future edition the three parts will be paged and bound as one volume, that the price will be reduced to a figure more suited to the size of the work and the means of the majority of students, and, finally, that the book will be provided with an index, the want of which in the present edition materially detracts from its usefulness. J. W.

NEW MAPS AND ATLASES.

The "Diagram" Series of Coloured Hand Maps. Designed by B. B. Dickinson, M.A., F.R.G.S., and A. W. Andrews, M.A., F.R.G.S. (London: George Philip and Son, 1900.). Price 1*s.* per dozen maps.

Philips' London School Board Atlas. Edited by G. P. Philip, Jun., F.R.G.S. Pp. 36. (London: G. Philip and Son, 1900.). Price 1*s.*

The London School Atlas. Edited by H. O. Arnold-Forster, M.A. Pp. 48. (London: The London School Atlas Co., Ltd., 1900.). Price 2*s.*, 3*s.* and 3*s.* 6*d.*

GOOD maps are essential to the success of geographical instruction. The best method of obtaining a true knowledge of the relation of the various land and water surfaces of the earth to one another, their relative dimensions, and their distribution in latitude and longitude, is by the use of a good terrestrial globe; but maps are indispensable even when globes are used, for they show in detail what can only be represented upon a small scale on a globe of the size used in schools. Each of the collections of maps, the titles of which are given above, has its good points, and all of them will assist in the intelligent teaching of geography.

The coloured hand maps prepared by Messrs. Dickinson and Andrews are the best orographical maps suitable for school use which have come under our notice. No names are printed upon the maps, but the elevations of the country are represented in five or six grades of colour, and the chief rivers are inserted. With maps such as these before him, a pupil can see at once how the general direction of river flow is determined by difference of level. He can, for instance, follow with intelligent interest the courses of the Ganges and Brahmaputra Rivers from the Himalayas down to their delta and the Bay of Bengal. The grades of colouring of

different levels of land show clearly that the directions taken by these rivers are the only possible courses for water running downwards to the sea. The course of the Amazon and its tributaries across South America can similarly be understood by a glance at the orographical map. There are thirty maps of this kind in the series, and they are uniform in excellence. They thus bring out prominently the importance of land elevation, and used as they are intended to be—for pupils to fill in the details of physical, political and commercial geography—they will be of real educational value. In the absence of relief or contour maps, the "Diagram" series of orographical maps provide an admirable introduction to the study of geographical science. To convey the idea of comparative size, Great Britain or the British Isles is represented in one corner of each map on the same scale as the map itself. The maps can be supplied as lantern slides, as well as in several forms suitable for school requirements.

Among the noteworthy characteristics of Mr. George Philip's atlas are its remarkable cheapness—the price is only 1*s*.—and the selection of important geographical features to which prominence is given. There are in the Atlas forty coloured plates, containing ninety maps and plans, and eight pages of introductory letterpress. Physical features are clearly represented, and the scale is stated under each map. The difficulty of distinguishing between political boundaries and lines bordering physical features has been successfully overcome by printing the former in distinct red lines. The maps have not the common defect of being overcrowded, and they are up to date both as regards the spelling of names and political divisions. To ensure that the pupil understands the meaning of a map, several views and plans are given side by side; and there are also maps of the County of London and the Thames Basin. These special supplementary maps can be modified to suit local requirements. There is no excuse for using obsolete maps filled with confusing and unnecessary details now an Atlas such as that by Mr. Philip is available.

The Atlas edited by Mr. Arnold-Forster is constructed upon the same intelligent principles as the preceding one; the maps are well drawn, beautifully coloured, not overcrowded, and the place-names have been carefully selected. Views, plans and sections are shown under one another in the introductory maps to provide lessons in map reading. There are also maps of the same district on different scales, illustrations of methods of showing elevation, as used in Ordnance Survey maps, and a reduced Admiralty chart of the Needles to show the method of sea-mapping. Several good astronomical diagrams show some of the phenomena connected with the rotation and revolution of the earth, but Map 8 is incorrectly designated the Solar System; for all that comes under this head in it are the earth in its orbit at the equinoxes and solstices, and the lines representing the relative lengths of the diameters of the sun, earth and moon. Following these maps are forty others upon which the various continents and countries of the world are represented according to their physical features or political divisions. Several maps are devoted to the representation of the growth of the British Empire. Dr. A. J. Herbertson contributes some notes on the construction and reading of maps, and teachers will learn from them how the Atlas can best be used and appreciated.

The appearance of these Atlases at about the same time indicates, we hope, that more careful attention is to be paid to instruction in geography in the future than is now given in most schools. The maps represent the best that have yet been prepared at a low price for use by individual pupils, and their adoption can be recommended to all teachers of geography.

OUR BOOK SHELF.

Die Photographie im Hochgebirg. Von Emil Terschak. Pp. xv + 87. (Berlin: Gustav Schmidt, 1900.)

In this neat little book of some 90 pages, the author gives the reader some practical hints, both in word and illustration, as to the road to success in mountain photography. The hand camera is now so generally used, owing to the rapidity of modern lenses, and there are so many of us who like climbing, and who always carry one of such instruments on our tours, that such a book as this, full of practical hints, will be welcomed. Mountain photography is quite an art in itself, and he who is a good picture-maker near the sea level does not necessarily meet with success when some thousand feet or so up. The effects to be portrayed at that height are of quite a different nature. There we have great contrasts of rock and sky, clouds lying at our feet, mists hanging about different hill-sides, and snow-capped peaks and glaciers adding to the beauty of the landscape.

Each of these cannot be immediately reproduced on the photographic plate without either a great experience in the class of work, or a careful study of the labours of others. In this book the author brings together in an enticing manner the chief points to be borne in mind when making a tour. He commences with useful information relative to the packing up of the camera, plates, &c., and then in turn treats of the several conditions under which the photographer is likely to work—such as photographing mountains from a valley or *vice versâ*, mountain groups from a height, clouds, mists, &c. The author accompanies his remarks with numerous excellent reproductions from his own negatives, and in every case gives data, such as the kind of plate used, lens, stop, length of exposure, time of day and year. Every one who is familiar with the German language, and is interested in mountain photography, will be sure to find this a serviceable book.

An Introduction to Vegetable Physiology. By J. Reynolds Green, Sc.D., F.R.S., Professor of Botany to the Pharmaceutical Society of Great Britain. Pp. xx + 459. (London: J. and A. Churchill, 1900.)

One of the needs most widely felt in modern botanical literature has been that of a good intermediate book dealing with vegetable physiology. Although several standard works dealing with this branch of botany are already in existence, they are for the most part of too advanced a character to be of much use to a junior student. It is a matter for gratification that the task of providing such a treatise should have fallen into such good hands as those of Prof. Green, by whom, as might have been expected, the subject-matter has been skilfully handled and admirably illustrated. By wisely avoiding excessive detail, and by duly emphasising from different points of view the various matters of special importance, the author has succeeded in producing a really excellent student's book, whilst the general reader will find the principal topics of current physiological interest presented in a lucid and interesting manner.

Of course it is not to be expected that such a work should be altogether perfect, and if we indicate some of the points which strike us as susceptible of improvement, we do so in the hope that the work may gain still further in value when future editions are called for.

Whilst many of the illustrations are distinctly good, some are very much the reverse, and as an example of the latter class Fig. 40 may be cited, which is excessively bad, and can hardly be said to illustrate the text (which it certainly does not adorn) in any sense whatever. The story of the digestive functions attributed to the leaves of *Lathraea* is now generally discredited, and might as well have been omitted from the text, whilst the somewhat teleological explanation of the red colour in leaves perhaps might at least have been accompanied by suggestions as to the proximate causes of its appearance such as are indicated by Overton's recent experiments. It is, however, against the short chapter on the influence of the environment on plants that we incline to take the greatest exception. The subject is a large one, and can only be adequately, or even usefully, treated by the aid of copious illustrative examples, without which as in the present instance it is apt to degenerate into rather senseless cramming.

Apart, however, from what after all are but minor and easily remedied faults, the book is, as we have already said, a decidedly good one, and its author has displayed such excellent judgment in the selection of his materials in order to meet the special needs of the class of readers for whom it is primarily designed that there will in future be no excuse for that neglect of vegetable physiology which is at present but too common with junior students of botany. J. B. F.

A Text-book of Important Minerals and Rocks, with Tables for the Determination of Minerals. By S. E. Tillman, Professor of Chemistry, Mineralogy and Geology, U.S. Military Academy, West Point, N.Y. Pp. 176. (New York: John Wiley and Sons. London: Chapman and Hall, Ltd., 1900.)

IN this little manual, Prof. Tillman has brought together such fundamental instructions as are necessary to enable a beginner to determine the most commonly occurring minerals and rocks. Three short chapters on crystallography, the chemical characters, and the physical properties of minerals are followed by a series of tables for the determination of 135 common species. In the choice of these species a considerable amount of judgment is shown, though it is obvious that the opinions of an American mineralogist as to what should be regarded as the most important species differ from those of workers in Europe. The tables are on the familiar plan of those of Weisbach, Persifor Fraser, Brush and Penfield, and other well-known authors, and the arrangement adopted is a very simple one. The twenty pages devoted to rocks at the end of the volume are only sufficient to enable the author to give a very slight sketch of petrographic science. The work is worthy of the attention of teachers organising a system of very elementary instruction in determinative mineralogy.

Laboratory Companion for Use with Shenstone's Inorganic Chemistry. By W. A. Shenstone, F.R.S. Pp. vi + 117. (London: Edward Arnold, 1901.)

MR. SHENSTONE'S course of work in inorganic chemistry was noticed in these columns a few weeks ago (January 10, p. 249). Most of the experiments in that book are reprinted in the present volume, together with a number of exercises, and other experiments have been added. A volume suitable for use as a laboratory manual, that is, containing directions and suggestions, without theoretical considerations, has thus been produced. On p. 117 reference is made to a frontispiece showing Fraunhofer lines, but the picture has been omitted.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

A Compact Method of Tabulation.

IN arranging tables of successive values of a variable quantity, it is often difficult to find a middle course between making the entries too numerous and making the intervals too large. I wish to call attention to a mode of tabulation which, although compact, provides facilities for the accurate deduction of intermediate values.

For convenience of description we may regard the tabulated values as equidistant ordinates of a curve. If the common distance is small enough (which implies that the number of ordinates is large), intermediate values can be deduced by the ordinary method of "proportional parts"—in other words by employing first differences only. If the number of ordinates is diminished by largely increasing the common interval, it becomes necessary to take account of differences higher than the first. We shall suppose the interval to be so chosen that the first three orders of differences—and no more—require to be considered.

A table showing the given values accompanied by three columns of differences presents a formidable aspect; and on the other hand, if the user of the table is left to compute these differences for himself, his labour is materially increased. What I wish to point out is that, without any sacrifice of accuracy, the first and third orders of differences can be omitted, the second only being retained; as in the following table of sines, which is suitable for computing the sine of any angle to four places of decimals. The differences entered opposite the sines are the "central" second differences; for example, −104, which stands opposite to sin 20°, is (sin 30° − sin 20°) − (sin 20° − sin 10°).

Angle	Sine	Second difference	Angle	Sine	Second difference
0°	·0000	− 0	50°	·7660	− 232
10	·1736	− 52	60	·8660	− 263
20	·3420	− 104	70	·9397	− 286
30	·5000	− 152	80	·9848	− 299
40	·6428	− 196	90	1·0000	− 304

Let $u_0\ u_1$ be any two consecutive tabulated ordinates (sines) between which it is desired to interpolate a new ordinate u; $x_0\ x_1\ x$ being the corresponding abscissas (angles). Putting h for the common interval $x_1 - x_0$, let p stand for $\frac{x - x_0}{h}$, and q for $\frac{x_1 - x}{h}$, so that $p + q = 1$. Also let $u_0''\ u_1''$ denote the central second differences of $u_0\ u_1$ respectively. Then it can be shown that the value of u true to third differences is

$$pu_1 + \frac{p(p+1)(p-1)}{1 \cdot 2 \cdot 3}u_1''$$
$$+ qu_0 + \frac{q(q+1)(q-1)}{1 \cdot 2 \cdot 3}u_0''.$$

The sum $pu_1 + qu_0$ of the two terms in u_1 and u_0, though it does not put first differences in evidence, really includes them, and is the exact value of u when the connecting curve is a straight line. In like manner, though third differences are not in evidence, they are implicitly contained in the sum of the two terms in $u_1''\ u_0''$.

The coefficients of $u_1''\ u_0''$ are identical in form, and are easily computed. The following list of their values for each tenth of an interval will serve to check mistakes. Their values (neglecting sign) are always less than ·065.

$$\frac{p(p+1)(p-1)}{1 \cdot 2 \cdot 3}$$

p		p		p	
·1	− ·0165	·4	− ·0560	·7	− ·0595
·2	− ·0320	·5	− ·0625	·8	− ·0480
·3	− ·0455	·6	− ·0640	·9	− ·0285

Two examples will show the working of the method.

To find sin 36°, we have $p = \cdot 6$, $q = \cdot 4$.

$$
\begin{aligned}
\cdot 6\ (\cdot 6428) &= \cdot 38568 \\
\cdot 4\ (\cdot 5000) &= \cdot 20000 \\
\cdot 064\ (\cdot 0196) &= \cdot 00126 \\
\cdot 056\ (\cdot 0152) &= \cdot 00085 \\
\hline
& \quad \cdot 58779 \quad \text{say } \cdot 5878.
\end{aligned}
$$

To find sin 72° 30′, we have $p = \frac{1}{4}$, $q = \frac{3}{4}$, giving $-\frac{5}{128}$ and $-\frac{7}{128}$ as the coefficients of $u_1'' u_0''$. Hence we obtain

$$
\begin{aligned}
\tfrac{1}{4}\ (\cdot 9848) &= \cdot 2462 \\
\tfrac{3}{4}\ (\cdot 9397) &= \cdot 70478 \\
\tfrac{5}{128}\ (\cdot 0299) &= \cdot 00117 \\
\tfrac{7}{128}\ (\cdot 0286) &= \cdot 00156 \\
\hline
& \quad \cdot 95371 \quad \text{say } \cdot 9537.
\end{aligned}
$$

Both these results are correct to the last figure.

The formula of interpolation here employed (which can be carried to higher terms when necessary) seems to be new. I gave it to Section A at the last meeting of the British Association, and have illustrated its use more fully in the *Journal of the Institute of Actuaries* for last month (January). It will also appear with other kindred matter in the next number of the *Quarterly Journal of Mathematics*. J. D. EVERETT.

Frost Fronds.

ON the morning of January 29, as I was walking from this place down Haverstock Hill into London, about 9.30, my attention was attracted by the "frost fronds" on the flags of the footpath. I see instances not unfrequently, and have called attention to one variety, where they form divergent groups, like the sticks of a partly opened fan, resembling the well-known crystals of actinolite obtained on the southern side of the St. Gothard Pass (see *Proc. Roy. Soc.* lxiii. p. 217, and *Quart. Journ. Geol. Soc.* liv. p. 368); but those now mentioned were characterised by unusual delicacy and grace. They formed groups, often half a yard in diameter, composed of frond-like radiating tufts, made up of thin stems or acicular crystals (often some four inches long and about the thickness of a bodkin) beautifully curved: this almost invariable bending of the "blades" being the most marked characteristic. They resembled very delicate seaweeds, dried and displayed on a card as an ornamental group. In descending the hill I observed that the crystals became a little coarser and more like those already mentioned. Also that sometimes clots of frozen mud appeared near the junction of the fronds, as if a trefoil or quatrefoil leaf had been placed there to hide it. I attribute the unusual delicacy of the fronds to the fact that the previous evening had been showery, and so the pavement had been cleaned of all but the very finest mud, after which had come a drying wind and a frost. Thus crystallisation probably occurred in a very thin film of slightly turbid water and on a fairly smooth surface, so that opposition to it was comparatively slight and the circumstances approached more nearly to the crystallisation of water on glass. I could not linger to make a minute study as I was pressed for time, but write this in the hope that some one who can take photographs (which I cannot) will collect examples of "frost fronds," for I believe they would be helpful in interpreting crystal building in rock masses. T. G. BONNEY.

23 Denning Road, Hampstead, N.W., January 31.

The Total Solar Eclipse of May 17–18.

THE Board of the Koninklijke Natuurkundige Vereeniging at Batavia has applied to the Government in regard to the custom duties to be levied from scientific observing parties who may visit the Dutch colonies for the observation of the total solar eclipse on May 17–18. The following reply has been received.

No duties will be levied on goods not exempted by the tariff, but destined to be re-exported after the observation of the eclipse has been concluded; observing parties may obtain further information from the chief Custom House officer at the port of arrival.

Besides all possible facilities in having their goods imported, exemption from search will be afforded to scientific expeditions.

We feel much pleasure in bringing the above under the notice of intending observing parties. J. J. A. MULLER.

January 1. (President of the Kon. Natuurk. Ver., Batavia).

The Museum of the Institute of Jamaica.

IN connection with your items regarding the possible return of Dr. J. E. Duerden, curator of the Jamaica Institute Museum, to England, may one who has spent two summers in Jamaica engaged in zoological research, and who has enjoyed the hospitality of Dr. Duerden and other men of science there, be permitted to say a word as to the causes which have led to the present unfortunate situation? There are two such principal causes, I believe, not closely related, but in this case working together toward a common end. The most important of these is local jealousy, against which Dr. Duerden has had to contend constantly ever since his arrival at the island. At the time he was appointed, a large and influential element among the supporters of the Institute desired the appointment of a young Jamaican, who had received some training in England, and who was doubtless well qualified for the duties of the position. His failure to secure the office was a bitter disappointment, not only to himself, but to his friends, and Dr. Duerden entered on his duties with an unfortunately large number of hostile critics, watching for opportunities to find fault. It is very possible—in fact, since Dr. Duerden is human, it is highly probable—that opportunities for criticism arose, and possibly the criticisms have not always been met in the wisest possible spirit. But it is clear to me, and I think I can speak for all the Johns Hopkins men who were in Jamaica, that if Dr. Duerden's local critics had been as anxious to help him and build up the museum as they were to find fault, there would be no trouble at the present time. I do not mean to say that Dr. Duerden has been entirely blameless, but I feel sure that his responsibility for the trouble is very much less than that which rests on his critics. The fact that Dr. Duerden is a trained investigator, and has given a large share of his time to research work, has given opportunity for criticism from those who believe the curator ought to devote his time to adding new specimens to the exhibition collection and labelling them all properly.

The other cause of the proposed retrenchment is one which appeals to me strongly, and must, I think, to all unprejudiced persons who know the facts. The colonial expenses are greater than the income, and the debt is already heavy. A very large proportion of the expense account is made up of salaries paid the English civil officials, from Governor down. The Governor receives a salary of 6000*l.*, besides two residences and the usual perquisites of his position. This salary is grotesquely enormous under the circumstances. Jamaica is not only a delightful place to live in, a veritable paradise in many respects, but it is a very cheap place as well. I should estimate, from my slight experience there, that living expenses are about three-fifths of what they are in the eastern United States. Most Englishmen in Jamaica do not realise or believe this, for they still cling to English food and English customs. Now the colony, a few years ago, attempted to secure the reduction of the salaries of colonial officials, and suggested a saving of 1000*l.* on the Governor's salary, but the proposition was promptly ended by that official's veto, which is absolute. So every attempt to decrease expenses by decreasing salaries has failed, and now retrenchment has to come somewhere, and since a zoologist is of small account, especially one who has some powerful enemies, Dr. Duerden is to be sent back to England. If this event actually takes place the blame will rest, not on Jamaica, but on England. There is little chance for the advance of scientific research in that island so long as it is looked on by English politicians as a possession to be exploited for the benefit of the office-holders.

I trust it is not yet too late for the scientific men of England to make such an emphatic protest to the proper authorities that the Board of Governors of the Jamaica Institute may be compelled to retain Dr. Duerden as curator of the museum, if he can be persuaded to stay, and if not, to secure some equally competent and well-trained investigator to fill his place.

HUBERT LYMAN CLARK.

The Mongoose in Jamaica.

IN Jordan and Kellogg's admirable little book, "Animal Life," we read (p. 293):—"The mongoose, a weasel-like creature, was introduced from India into Jamaica to kill rats and mice. It killed also the lizards, and thus produced a plague of fleas, an insect which the lizards kept in check."

As it is evident from this and other signs that the Jamaica mongoose is to become celebrated in text-books, it seems worth while to call attention to the facts actually known about it. An excellent summary showing the status of affairs in 1896 was written by Dr. J. E. Duerden and published in the *Journal* of the Institute of Jamaica, vol. ii. pp. 288–291. In the same volume, p. 471, are further notes on the same subject.

The creatures which increased and became a pest were ticks; not fleas. The present writer can testify to their excessive abundance in the island in 1892 and 1893. The species were various, and were examined by Marx and Neumann, whose determinations appear in *Journ. Inst. Jamaica*, vol. i. p. 380, and vol ii. p. 470. It will be noted that the common species are not confined to Jamaica, and, in fact, have probably, most of them, been introduced from elsewhere. Hence it is quite possible that their abundance is in large part due to their recent introduction.

Thermochemical Relations.

LET us consider gr. 2 of H, gr. 16 of O and gr. 71 of Cl, namely, volumes 2 of H, 1 of O, 2 of Cl. We can combine these corps two by two to form the three following compounds:—

gr. 87 of Cl_2O gr. 18 of H_2O gr. 73 of HCl

that occupy respectively 2, 2, 4 volumes.

The heats of combination are respectively:—

$$-14 \qquad +58 \qquad +44,$$

between which is the simple relation

$$-14 + 58 = 44.$$

In another example, where one of the components is solid but remains the same ratio between the volumes of the compounds, we have again the same relation between the combining heats. In fact, with

gr. 2 of C gr. 4 of H gr. 32 of O

we can form

gr. 16 of CH_4 gr. 44 of CO_2 gr. 36 of H_2O

which occupy respectively 2, 2 and 4 volumes.

The combining heats are respectively

$$+19 \qquad +97 \qquad +116,$$

and we find

$$19 + 97 = 116.$$

Is it a casual coincidence or a law?

Spezia (Italy), Nov. 14, 1900. CARLO DEL LUNGO.

Direction of Spirals in Horns.

ABOUT Mr. Blanford's interesting remarks on my letter in NATURE for January 10, I should like to answer that, far from thinking the matter "simple," I find that the facts are nowhere recorded and certainly are not generally known to naturalists or sportsmen. This is why I attempted to formulate rules.

The rule that in antelopes the direction of the spiral is "crossed" (*i.e.*, the right horn is sinistral, and the left horn is dextrorsal) holds good in the Koodoos, Elands, Indian antelope, Bushbuck, Impalla, and Speke's antelope (noted by me in the *Lancet*, January 1, 1898, "On Spiral Growth").

In oxen the horns are "homonymous" in direction—the right horn twists to the right, the left horn to the left—and many horns show a good spiral. I may mention the Cape buffalo, musk ox, domestic ox, also the Urus and the Chartley bull. The only exception to the rule in the Cambridge Museum is an Indian buffalo.

In the sheep, the direction of the spiral is "homonymous," as in the ox, except *Ovis orientalis* and *Ovis nahura*.

In the goats, Mr. Blanford, in his "Fauna of British India, Mammalia," notes that there is a difference between the wild and the tame goats in the following passage: "But the spiral in tame goats is almost always in the reverse direction to that found in Markhor, the anterior ridge in the tame animals turning inwards at first in each horn.

"I have, however, seen exceptions; there is one from Nepal in the British Museum."

After searching many books on horns (including Mr. Lyddeker's), this is the only note on the direction of spirals that I can discover. The causes of the spirals, and of the differences in directions, are still to seek.

Cambridge. GEORGE WHERRY.

SOME DISPUTED POINTS IN ZOOLOGICAL NOMENCLATURE.

AMONG that large section of the general public who are interested, to a greater or less degree, in natural history there is a widely spread impression that, as most of the more familiar animals have a single, definite and indisputable popular designation, so every known species in the animal kingdom has one proper technical title by which it is known throughout the zoological world; and consequently that when they have once made themselves acquainted with this title, there is no more to be said on the subject. To a certain limited extent (some authorities would, perhaps, be inclined to say invariably) there is no doubt that this idea is perfectly well founded. But, in the first place, there is a difference of opinion among zoologists as to the limits of genera, and whereas one worker would retain a species in the genus in which it was placed by its original describer, another would regard it as entitled to represent a genus by itself. Thus one great element of diversity in nomenclature is introduced.

But there are also a very large number of cases in which an equal diversity of view obtains as to the proper specific title of an animal. And the inquirer will not be long in ascertaining that, in place of unanimity, an almost chaotic state of uncertainty prevails as to what should be the proper binomial designation of a large percentage of animals. Consequently, in place of being one of the easiest, the question of nomenclature is, in many cases, one of the most difficult; and the unhappy inquirer will too often find that he receives a different answer from almost every authority to whom he applies. Nor is this all, for whereas a considerable number of systematic zoologists are agreed in some measure upon certain general principles of nomenclature, their opinions are not shared by many of the workers in palæontology, morphology and geographical distribution, who adhere to more antiquated views on these questions.

The reasons for this regrettable and unfortunate state of affairs are many and varied. And as a crisis on the question is likely to arise in the near future, if indeed it be not already upon us, the editor is of opinion that there are many readers of NATURE who would like to be informed of some of the chief points at issue, and of the more important suggestions which have been made towards arriving at a settlement. It will consequently be understood that the present article has been written solely from this point of view, and that it makes no pretence to discuss all the questions, or to enter into details interesting to zoologists alone.

One of the points at issue—and it is one of the most important—is what we may term the theory of the sacredness and immutability of the specific name. Soon after Linnæus had completed the last edition of the "Systema Naturæ" published under his own personal supervision, it became apparent that a large number of the animals named by him could no longer be permitted to remain in the genera in which they were included in that work. The giraffe, for example, which had been named *Cervus camelopardalis* by the Swedish naturalist, was certainly entitled to generic distinction from the deer. At this date the idea of the "sacredness" of the species name had not yet originated, and Gmelin, in his edition of the

"Systema Naturæ," considered himself justified in "promoting" the specific title *camelopardalis* to generic rank, and proposing a new specific name for the animal thus designated. *Cervus camelopardalis*, Linn., thus became *Camelopardalis giraffa*, Gmelin. Similarly, in much later years, Gray changed the *Antilope strepsiceros* of Pallas into *Strepsiceros kudu*. According, however, to the modern school of zoologists, such changes were totally unjustifiable; and they hence advocate what is known as the "*Scomber scomber*" principle, on which the title of the kudu becomes *Strepsiceros strepsiceros*. To many (among them the secretary of the Zoological Society) such tautological titles are most repugnant; and in the case of the animal last mentioned they accordingly prefer to retain the title proposed by Gray. In the case of the giraffe, by a fortunate circumstance, the difficulty does not arise, for the generic title *Giraffa* had been proposed at an earlier date than the "promotion" of *Camelopardalis*, and the name of the animal consequently became automatically *Giraffa camelopardalis*. If the "sacredness" of the species name be insisted upon, and the tautology objected to, a way out of the difficulty in the case of the kudu and many other analogous instances might be found by making a new generic title, when the animal might be called *Kudua strepsiceros*. But the case of the striped hyæna, the *Canis hyaena* of Linnæus, then arises as an example of another difficulty. For this animal was subsequently named *Hyaena striata*, altered by the modern school to *Hyaena hyaena*; and if we refuse to accept the latter and yet desire to retain the original species name, we have to abrogate such a familiar generic title as *Hyaena*, and likewise the family name *Hyaenidae* (for there are but few who would advocate the retention of a family name when the generic title from which it is derived is abolished). The older naturalists, in the absence of any law to the contrary, considered themselves perfectly justified in promoting the specific title to generic rank, and personally we fail to see on what grounds the present generation think themselves entitled to override this decision, as, in our own opinion, there is no right or wrong in the matter. That similar changes are now forbidden is, of course, fully understood.

But bad, in the opinion of many, as is the tautology of *Strepsiceros strepsiceros*, worse is to follow. By those who admit the principle of "trinomialism" to designate local races of animals, if the kudu were divisible into two or more such races the typical form would, according to American writers, become *Strepsiceros strepsiceros strepsiceros*. And, again, if the lesser kudu were subgenerically separated from the larger species, the title of the typical race of the latter would become *Strepsiceros* (*Strepsiceros*) *strepsiceros strepsiceros!* We do not like to use the term absurdity in connection with the views of others, but it becomes almost difficult to refrain.

That some designation is advisable for local races of species is admitted by nearly all, but there is still a reluctance among many to accept the aforesaid trinomialism. To many such the interpolation of the word "var." between the specific and the racial title appears preferable; and to this plan there can be no objection, albeit it is somewhat more cumbersome. It must, however, be borne in mind that when the word "var." is inserted the third title must agree in gender with the species name, whereas in trinomialism proper it agrees with the genus name. To avoid tautology, many zoologists use the designation "typicus" for the type race of a species, but this usage is objected to by others in that it is practically a new subspecific title.

This, again, leads us to notice a modern change in regard to subgeneric titles. Formerly, when a genus was divided into subgenera, a new subgeneric name was proposed for the typical group, *e.g. Cervus* (*Eucervus*) *elaphus* for the red deer. Now, however, the practice is to repeat the generic name, as instanced above in the case of the kudu. In this connection it may be noticed that even those who object to the "*Scomber scomber*" principle come perilously near to it when subgeneric terms are employed, as in *Cervus* (*Dama*) *dama* for the fallow deer, which they would call *Dama vulgaris* if regarded as a separate genus. It should likewise be mentioned that the bracketing of a name is only admissible when it is used in a subgeneric sense, as above. Consequently the practice of indicating a synonym in this manner, *e.g. Microtus* (*Arvicola*), is totally unjustifiable, although it is frequently practised by biologists other than systematists.

The mention of *Microtus*, the title now employed by the modern school to designate the voles in place of *Arvicola*, which was in almost universal use a few years ago, brings us to the vexed question of priority. Although there are still many zoologists who adhere to the practice of using names (both generic and specific) which, in spite of not being the earliest, have been current in literature for a long period, the general trend of opinion is all in favour of the enforcement of the rule of priority (even to the bitter end) among systematists. In the main, it must be confessed that the advocates of this have reason on their side, as otherwise we are landed in almost hopeless difficulties. But admitting the general principle to be the most logical, may there not be room for the exercise of some discretion and common sense? A naturalist, for instance, years ago described, from a cave in America, what appears to be an upper premolar tooth of the white-tailed deer, to which he gave the name *Odocoileus*, on the supposition that it represented an unknown type of animal. As a matter of fact, he ought to have referred it to the genus *Cervus*, as that genus was then understood. Yet American naturalists propose to adopt this name for the white-tailed deer and its allies. Such usage is a premium on incompetence and ignorance; and it does not seem fair that names so given should supersede those proposed by workers who know their business. Of course there are many difficulties when the discretionary element is once introduced, but, like all others, they are not insuperable when properly handled.

One of the greatest evils arising from the wholesale change of names that has been introduced of late years through this revival of the right of priority is that it renders obsolete to a great extent works such as Dr. Wallace's "Geographical Distribution of Animals"—works that ought to stand for all time. It further involves the task of recollecting a double series of names if such works are not to be cast aside *in toto*. It is largely on this ground that so many biologists other than systematists refuse to conform to the new view. The evil induced by the change is undoubtedly great and much to be deplored; but it will certainly not be remedied by the refusal of one section of workers to follow in the footsteps of those of their brethren who alone have full opportunities of arriving at the best decision with regard to a matter bristling with difficulties.

From priority in nomenclature the transition to the question of preoccupation is an easy one. That the use of a generic name in botany is no bar to its employment is now generally conceded; but it is considered advisable that such names should be given as seldom as possible. Most zoologists are likewise agreed that when absolutely the same name has been once employed as the generic designation of any group of animals (whether it be in use or not), it cannot be employed for another. There is, however, a want of unanimity as to whether the same name with a different termination—*e.g. Hydropotes* and *Hydropota*, or *Mastodon* and *Mastodus*—may be used for two groups. Closely connected with this is the question whether the transliteration or grammatical formation of names should be amended—*e.g. Machairodus* to *Machaerodus*, or *Megatherium* to *Megalotherium*; and

whether, if they are not so amended, the use of both is admissible for different groups. Some even go so far as to say that an obvious error in the spelling of a name, as, for example, *Rhinchosaurus* in place of *Rhynchosaurus*, should not be amended, and that the previous use of the incorrectly spelt name should be no bar to its subsequent employment for another group in the correct form. To many, at least, of those who have even the slightest knowledge of the classics such a practice must be repugnant. And to a certain extent, at any rate, the same remark will apply to hybrid names, although the general consensus of opinion is now against the amendment of these. Less objection can be taken to meaningless names, or anagrams (such as *Xotodon*, the anagram of *Toxodon*), which, if euphoniously formed, serve their purpose fairly well. And the old objection against so-called barbarous names has of late years been waived by many workers. Although it is by no means a general view, such names are more euphonious when Latinised, as *Linsanga* in place of *Linsang*, and *Coendua* for *Coendou*. Then again there are names like *Camelopardalis* (giraffe), *Hippotigris* (zebra), and *Hippocamelus* (a deer), given on the supposition that the animals to which they refer are intermediate between the two indicated by the compound title. The two former have late classical authority, and may further be justified on account of the coloration of the animals to which they refer, but to some persons, at least, the acceptation of the third is objectionable. It must be confessed, however, that when once individual fancy is allowed play in matters of this sort, it is difficult to know where to draw the line.

Another class of names are those which have been given to species on the evidence of maimed specimens, or examples whose place of locality was incorrectly recorded. The great bird-of-paradise was thus named *apoda*, while the name *ecaudatus* has similarly been applied to at least one mammal. Again, a bear inhabiting the Himalaya has been named *tibetanus*, while there are even more flagrant instances of misapplied geographical titles. Many workers of the modern school assert that no errors of this kind should be amended; while some would even say that although Tibet is the accepted modern way of spelling the country of the lamas, yet that if the specific title was originally spelt *thibetanus*, so it must remain for all time. A common-sense, rather than a pedantic, view can, we think, be the only safe guide in such cases. When a name inculcates an error in geographical distribution, its retention, from this point of view, is clearly indefensible. So, again, in the case of names due to misconception or maimed specimens. Where, for instance, the name *ecaudatus* denotes a long-tailed animal, its retention is against common sense. On the other hand, where the feet of a bird are inconspicuous, as in the swift, no great exception can be taken to the use of the name *apus*.

The last point in dispute to which we have space to refer is the right of an author to withdraw a name proposed by himself in favour of some later title. A well-known instance of this is afforded by the name *Daubentonia*, proposed by Geoffroy in 1795 for the aye-aye, but, on account of preoccupation in botany, subsequently withdrawn by him in favour of Cuvier's name *Chiromys* (or *Cheiromys*, as it was originally spelt). Whereas the right of withdrawal was denied by Gray (and the older name revived), by Sir William Flower it was admitted. The modern tendency is to follow Gray. If the preoccupation of a zoological name by a botanical were now admitted, of course Geoffroy's change would be followed. The question is whether, being right according to the views of his own time, there is sufficient justification for saying that he acted *ultra vires*. Moreover, the possibility is to be borne in mind that the next generation of zoologists will revert to the view that the use of a generic term in botany bars its subsequent employment in the sister science.

To arrive at a settlement in regard to these and many other points in dispute will require forbearance and the subordination of individual inclinations to the voice of the majority; compromise and common sense being, we venture to think, at least as necessary as adherence to inelastic rules.

In the foregoing we have purposely refrained from making any reference to Mr. H. M. Bernard's proposal to abolish specific names in those forms of life "which cannot be at once arranged in a natural system," for the reason that, if we understand him aright, it is his intention that the abolition in question should apply only (for the present, at any rate) to corals, sponges, and perhaps other low types of invertebrates. Whatever, therefore, may be its merits or demerits, the proposal is not yet intended to apply to such forms of life as are capable of being arranged in some approximation to a "natural system"; and the discussion of the disputable points in connection with specific names alluded to above is accordingly not yet rendered superfluous.

R. L.

CHARLES HERMITE.

AMONG those mathematicians who assisted in making the nineteenth century, and more especially the Victorian era, a period of unparalleled activity in the scientific world, the name of Charles Hermite will be indelibly imprinted in our annals as that of one who did much to develop the study of higher algebra, geometry, analysis and theory of functions.

Charles Hermite was born at Paris in 1822, and at the age of twenty he entered the École Polytechnique. His mathematical genius was not long in showing itself, for shortly afterwards we find him corresponding, at the instigation of Liouville, with Jacobi on the subject of Abelian functions, and the predictions of the latter mathematician that Hermite would soon extend the fields of study which he himself had done so much to open out was soon verified. From the theory of continuous functions Hermite soon passed on to the theory of forms, and gave a general solution of the problem of arithmetical equivalence of quadratic forms. He also discovered a new arithmetical demonstration of Sturm's and Cauchy's theorems on the separation of roots of algebraic equations.

The study of higher algebra, which sprang into existence with the discovery of invariants, was opened up simultaneously by Cayley, Sylvester and Hermite, and it would appear that to the latter mathematician we are indebted for the law of reciprocity, the discovery of associated covariants and gauche invariants, and the formation of the complete system of covariants of cubic and biquadratic forms and invariants of the quintic. Concurrently with these researches in arithmetic and algebra, Hermite was engaged on the study of the transformation of hyperelliptic functions and expansions of elliptic functions, and he was also the first to show that the number of non-equivalent classes of quadratic forms having integral coefficients and a given discriminant is finite. In 1856 Hermite was elected to the Institut, being then thirty-four years of age. In 1858 he took an important step in connection with the study of elliptic and theta functions by introducing a new variable connected with the q of Jacobi by the relation $q=e^{\iota\pi\omega}$, so that $\omega=\iota k'/k$. He was then led to consider the three modular functions denoted by $\phi(\omega)$, $\chi(\omega)$ and $\psi(\omega)$.

A transcendental solution of the quintic involving elliptic integrals was given by Hermite, the first paper appearing in the *Comptes rendus* for 1858 and subsequent papers in 1865 and 1866. After Hermite's first publication, Kronecker, in a letter to Hermite, gave a second solution, in which was obtained a simple resolvent of the sixth degree.

We are also indebted to Hermite for the first proof that e, the base of the Napierian logarithms, is transcendental, a result which paved the way for Lindemann's proof that the same is true of π.

In 1862 Hermite was elected to a newly founded chair at the École Normale, and later on he also became professor at the École Polytechnique and the Sorbonne. Instead of continuing to teach on the old lines which he found still in vogue, Hermite introduced into his lectures the great discoveries of Gauss, Abel, Jacobi and Cauchy. He thus founded for France a new school of higher geometry, and the large number of mathematicians of distinction who have studied under him bear abundant testimony to the success of his innovation.

During the later period of his life Hermite appears to have directed his attention more especially to questions connected with the calculus. In conjunction with Darboux and Jordan, he presented the general theory of linear differential equations in an entirely new light, choosing the algebraic rather than the geometric method of presentation. His work on Lamé's equation leads to the solution of a large number of problems in applied mathematics.

The "Cours de M. Hermite" constitutes an important work on the theory of functions.

About eleven years ago Hermite delivered an inaugural address before the President of the French Republic, which was published in the *Bulletin des Sciences mathématiques* for January 1890. In 1892 he celebrated his jubilee, and it is remarkable that the same year witnessed also the jubilee of Pasteur. The new century and the new era in history which has come upon our country will both be the poorer for the loss of M. Hermite, but his works will be handed down to posterity.

An account of his work has been given in the *Comptes rendus* for January 21 by M. C. Jordan, himself the author of important papers on the fields of study which Hermite had chosen to work in. To this account we are indebted for much matter contained in the present notice, and we are glad that M. Jordan pleads for the publication of Hermite's collected works. Many of his ideas are scattered in journals or letters that are difficult of access, and it will be of inestimable use to mathematicians to have them printed in book form.

G. H. B.

ADOLPHE CHATIN.

ADOLPHE CHATIN died on January 13 at the age of eighty-seven. He was a native of Dauphiné, and was born at Ile-Marianne-de-Saint-Quentin, near Tullins, "d'une famille peu fortunée," according to M. Gaston Bonnier, from whose éloge in the *Comptes rendus* of the Paris Academy (January 21) some of the following facts of his life-history are taken. He received his early education at Tullins, and at seventeen joined an apothecary at Saint-Marcellin. Three years later (1833) he went to Paris under an apothecary named Briant, who, recognising his pupil's capabilities, urged him to study pure science as well as pharmacy. Chatin, who always gratefully remembered his good friend's advice and encouragement, worked to such effect that he took bachelors degrees both in Letters and Science, and six years after his arrival in Paris obtained the degree of Doctor of Science. In the next year, 1840, he read his thesis before the School of Pharmacy, and was duly admitted. The somewhat ambitious title of this thesis, "The Comparative Anatomy of Plants applied to Classification," indicated the line of work in which he has done most service to botany. It was a short paper dealing with the occurrence, structure and general properties of albumen in plant-seeds. He took the view that the presence of endosperm in the seeds, implying a temporary arrest in the embryogeny of the plant, indicates a lower condition than that existing in the exalbuminous seed. "From this time," he tells us in the introduction to the "Anatomie Comparée des Vegetaux," "comparative anatomy was (with plant symmetry) the principal object of my labours."

In 1844 he took the degree of Doctor of Medicine, and in 1848 was elected to the chair of Botany at the School of Pharmacy, his chief competitor being M. Payer. Twenty-five years later he became Director of the School, retiring in 1886 with the title of Honorary Director. In 1874 he was chosen a member of the Academy of Science, succeeding Claude Gay, and in 1897 became President of the Academy. He was also a member of the Academy of Medicine, and filled various other posts of honour.

His first memoir, published in 1837, was on the symmetry of structure of plant organs, and sixty years later appeared the last part of his studies on the symmetry of the vascular bundles of the petiole. His best-known work is the "Anatomie Comparée" (1856-1862), which was never completed. It consists of two parts, the larger illustrated by 113 plates, on Dicotyledonous Parasites, the smaller with 20 plates, on Aquatic Monocotyledons. It is difficult to estimate the value of this work. Its chief worth lies in the beautifully executed figures illustrating the anatomy of the stem, leaf and root of a large number of genera and species. Their preparation implies considerable skill and much hard, conscientious labour, with which the results, as embodied in the text of the book, are scarcely commensurate. But it is hard to judge the work of forty years ago from our present standpoint, and in helping to revive the study of plant-anatomy, which had fallen into neglect, Chatin did good service, and might well, in his later years, regard with some complaisance and pride its present important position as one of the factors in the evolution of a natural system of plant-classification.

Chatin also studied the organogeny of the flower, especially of the andrœcium, and collected the results of numerous small papers, which had previously appeared in the *Comptes rendus* and elsewhere, in a volume entitled "De l'Anthère" (1870)—a comparative account of the development, structure and mode of dehiscence of the anther in a number of families and genera. His memoir on the life-history and structure of *Vallisneria spiralis* is a useful piece of work, illustrated with characteristic elaborate detail. But he by no means restricted himself to the study of the symmetry and anatomy of plants; the subjects of his published works and papers comprise the results of chemical as well as botanical investigations. Among his earlier papers were several dealing with the occurrence of iodine in air and water, its presence in plant tissues and its effect on plant growth. He also wrote on the potato disease, the vine disease, and on the cultivation of truffles and other edible fungi, and published a small book on watercress.

For the past two years his health, hitherto robust, had been gradually failing, and his last days were spent in retirement at his country home at Essarts-le-Roi, near Rambouillet. His son, M. Joannes Chatin, a professor at the Sorbonne and a member of the Academy, has made a few contributions to botanical literature, but his work has been chiefly in other branches of science.

NOTES.

ARRANGEMENTS are being made by the Royal Academy of Sciences of Sweden to celebrate the third centenary of the death of Tycho Brahe, the founder of modern practical astronomy, on October 24, 1901, by a special meeting. It is also proposed to further commemorate Tycho's work by the publication of a facsimile of the original edition of his celebrated "Astronomiæ instauratæ mechanica," a perfect copy of which is in the library of the Academy. It is well-known that when at Wandesburg

in the year 1598, Tycho had this work printed in his own office, with the view to give the celebrities of his time an exact idea of the organisation of the observatory which he had left for ever. But the edition appears to have been small, for the only copies of the work now known to be in existence are two at Copenhagen, and one each at the British Museum, Prague, and Stockholm. Another edition was printed four years later at Nuremberg, but it is not nearly so fine as that printed by Philip de Ohr at Wandesburg. Subscriptions are invited for the facsimile of the Stockholm copy of the work, and should be sent to Prof. Hasselberg, Royal Academy of Sciences, Stockholm, Sweden, before March 1. The price is fixed at 2*l*. a copy.

THE gold medal of the Royal Astronomical Society has been awarded this year to Prof. Edward C. Pickering, of Harvard College Observatory. The medal will be presented at the annual general meeting of the Society, which will be held at 3 p.m. to-morrow (Friday).

ON January 28 Scottish geology lost a most successful and enthusiastic fossil-collector in Mr. James Bennie, who then passed away at the ripe age of seventy-eight years. He began, while an artizan, in early life to employ his leisure hours in gathering fossils from the Carboniferous formations around Glasgow and from the Glacial deposits of the West of Scotland. So successful were these excursions and so excellent his published descriptions of the results obtained from them that in the spring of 1869 he was invited to join the Geological Survey of Scotland as Fossil Collector. He was thenceforth able to devote his whole time to work which had previously been only possible for him in his scanty hours of leisure. His career in the Survey was marked by remarkable industry, insight and success. He acquired a more minute knowledge of the palæontological stratigraphy of the Carboniferous system than was probably possessed by any one else. He discovered the first recognisable traces of *Holothuria* in that system, and obtained remains of scorpions from many different horizons. To his acute faculty of observation we owe the first recognition of the little Arctic *Apus* among the deposits of lakes of the Glacial Period in Scotland. He was not only a lynx-eyed collector but wrote well, and supplied many interesting papers to the *Transactions* of the Geological Societies of Edinburgh and Glasgow. He was fond of English literature, and when too poor to purchase Tennyson's Poems, borrowed a copy and transcribed it all. The value of his work was recognised two years ago by the Geological Society of London, which awarded him the Murchison Fund. His gentle and kindly nature, his cheery helpfulness and his loyal devotion to duty made him a great favourite with his colleagues, from whom he retired in 1897 on a well-merited pension.

AT University College, London, last week Prof. Schäfer was presented with a testimonial subscribed for by a number of those who had been his pupils or who had worked in the physiological a boratory during his tenure of office as Jodrell Professor of Physiology. From a report in the *British Medical Journal*, we learn that the chair was taken by Prof. Thane, who sketched the main features of Prof. Schäfer's connection with University College, and spoke of the esteem in which he was held alike by pupils and colleagues. The presentation was made by Dr. Leonard Hill, F.R.S., who, in a short and sympathetic speech, referred to the way in which Prof. Schäfer had stimulated physiological inquiry, and won, not only the respect, but the affection of those who were privileged to learn from him or to work under him. The presentation took the form of a bowl and two platters of hammered silver, designed and made by Mr. Alexander, of University College School, and of a cheque for a sum of money which is to be devoted to founding a medal to be given for the encouragement of physiological research in University College. Prof. Schäfer, who was very warmly received, said that the occasion recalled to him another occasion in the same theatre some thirty years ago. He then learnt from the lips of Sharpey that he had won the medal in physiology, and received it from the hands of Huxley. He believed that that circumstance had determined him to follow physiology as a career.

DR. R. A. DALY, of the Department of Geology and Geography of Harvard University, is endeavouring to organise a geological and geographical excursion in the North Atlantic for the summer of 1901. Conditionally on the formation of a sufficiently large party, a steamer of about 1000 tons, specially adapted for ice navigation, and capable of accommodating sixty persons, will leave Boston on or about June 26 and return to the same point on or about September 20. The main object of the voyage will be to offer to the members of the excursion party opportunity of studying the volcanic cones and lava-fields, the geysers, ice-caves and glaciers of Iceland, the fiords and glaciers of the west coast of Greenland, and the mountains and fiords of Northern Labrador. Some attention will be paid to the hydrographic conditions of the waters traversed. Botanists, zoologists, ornithologists, mineralogists and persons interested in other branches of natural history may pursue independent studies. A hunting party may take part in the expedition; it could be landed for a fortnight or three weeks in Greenland and for about the same period in Labrador. Explanatory lectures on the regions visited will be given from time to time by the leader of the excursion, Dr. Daly, who will also act as guide on the Labrador coast, where he spent the summer of 1900. An inclusive fee of 500 dollars for each member will be charged, 250 dollars to be deposited with the leader of the expedition on or before March 15. Applications for membership should be addressed to Dr. R. A. Daly, Harvard University, Cambridge, Mass., U.S.A.

WE regret to have received information of the death of the Nestor of European botanists, Dr. J. G. Agardh, of Lund, who died on January 17 in his eighty-eighth year. Prof. Agardh was chiefly known for his work in marine algæ. He was a correspondant of the Section of Botany of the Paris Academy of Sciences.

A NATURAL History Section has been formed of the Hampstead Astronomical and Scientific Society, with the primary object of working out the local fauna and flora. Meetings of the section will be held from time to time, when exhibits will be made, papers read, and discussion on zoological and kindred subjects invited. The honorary secretary for the section is Mr. J. W. Williams, 128, Mansfield Road, Gospel Oak, N.W.

MR. WILLIAM H. CROCKER, of San Francisco, has offered to defray the expenses of a solar eclipse expedition to be sent by the University of California from the Lick Observatory to Sumatra to observe the total eclipse of the sun on May 17. An astronomer and assistants will sail from San Francisco on February 19, to be absent until July. It is proposed to establish an observatory camp somewhere within twenty miles of Padang, on the west coast of Sumatra.

THE "Historical Number" of the *Electrical Review* of America (January 12) is full of notes and articles of interest to students of electricity. The number contains several very readable and informing papers on various branches of electrical work, and a series of portraits of men who contributed to the progress of electrical science and industry during the past century.

WE learn from *Science* that Mr. J. W. Sprague, who died recently, left a will that should ultimately greatly benefit the Smithsonian Institution. It gives 85 per cent. of the interest on

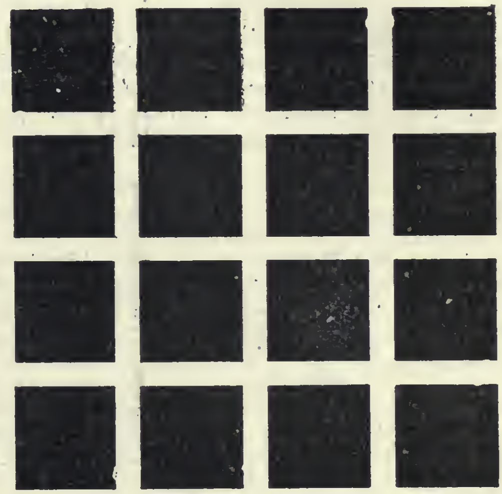
the estate to relatives for life. On their death the entire property, increased by 15 per cent. of the income to be laid by each year, is held in trust for twenty years, and then reverts to the Smithsonian Institution. One-half of the annual income is then to be added to the principal each year, and the other half is to be used for the advancement of the physical sciences by prizes, lectures or original research. It is estimated that the fund now is worth 200,000 dollars, and that it will be available in about fifty years.

DR. NORMAN MOORE will deliver the Harveian Oration of the Royal College of Physicians of London on St. Luke's Day, October 18, and Dr. Judson S. Bury, of Manchester, the Bradshaw Lecture in November. Dr. W. H. Corfield has been appointed the Milroy Lecturer for 1902. A subscription of fifteen guineas has been voted by the College to the fund for erecting a statue of Dr. William Gilbert, a former president, in the new Town Hall of Colchester. The adjudicators of the Weber-Parkes Prize for 1900 have reported that they have been unable to find any original work, published since the last award, which in their judgment would satisfy the conditions of the trust. Dr. J. F. J. Sykes will deliver the Milroy Lectures on February 28 and on March 5 and 7, on "The Influence of the Dwelling upon Health"; Dr. H. Head, F.R.S., the Goulstonian Lectures on March 12, 14 and 19, on "Certain Mental States associated with Visceral Diseases in the Sane"; and Dr. J. Frank Payne the Lumleian Lectures on March 21, 26 and 28, on "Cancer, especially of the Internal Organs."

FREE railway transport is granted to members of the staff of the New Mexico Agricultural Station engaged in experimental work and investigation, by the principal railway companies of the territory. This, remarks Dr. F. W. Sanders in a report just to hand, will enable the station to serve the public interests more perfectly than it has been possible to do in the past. Mr. A. Goss concludes, from results obtained during three years, that a number of districts in New Mexico can produce remarkably good beets, both as to sugar content and purity. Prof. T. D. A. Cockerell, the Station entomologist, who has for a number of years interested himself in the pigments of insects and plants, refers to a red colouring matter of the roots of the small borraginaceous plant *Eremocarya micrantha*, which may prove of service the properties of the pigment. The pigment belongs to the anthocyan series, and behaves exactly like litmus, turning red in the presence of acids, blue in the presence of alkalies. It is superficial on the roots, and readily soluble in cold alcohol. This pigment is thus an excellent native subs itute for litmus, and might possess commercial value. Not only is it purer than commercial litmus, but its preparation is very much simpler, and the roots are easily obtained. The matter is now being further investigated by the Division of Botany of the U.S. Department of Agriculture, and we shall doubtless be informed of the results before very long.

WE have received from Dr. Hergesell, President of the International Aëronautical Committee, an account of some preliminary results of the balloon ascents made on January 10. There were 15 ascents, including both manned and unmanned balloons; of these three started from Vienna, four from Berlin, and four from Strassburg. Altitudes varying from 4500 to 12,000 metres were attained by the unmanned balloons and some very low temperatures were registered. Three of the manned balloons ascended above 3000 metres. Several inversions of temperature with height were recorded—*e.g.* Vienna, 23°·7 at 500 metres, 34°·2 at 1000 metres, 32°·4 at 2000 metres; at Berlin, 25°·5 at starting, 32°·0 at 790 metres, 41°·0 at 1460 metres, 32°·4 at 2825 metres, while at 6670 metres the temperature had fallen to −22°·0. Ascents were also made at London and Bath, but the results are not given in Prof. Hergesell's summary. One of the balloons from Berlin, with Messrs. Berson and Hildebrandt, descended in Sweden after a flight of nearly fourteen hours.

A CURIOUS optical illusion is produced by the accompanying figure from *La Nature*. At the places where the white strips separating the black squares cross one another, a hazy penumbra can be seen. If, however, attention is concentrated upon one



of these spots it disappears, though the others remain visible. It would be interesting to vary the dimensions of the squares and intervening white spaces, and thus determine when the effect ceases to be seen.

THE thermal death-point of the tubercle bacillus is the subject of an important paper by Messrs. Russell and Hastings in the "Seventeenth Report of Wisconsin Agricultural Experimental Station." The general results obtained entirely confirm the experiments of Prof. Theobald Smith (see NATURE, vol. lxiii. pp. 166 and 205), and are as follows:—"(1) Exposure of tuberculous milk in a tightly closed commercial pasteuriser for a period of ten minutes destroyed in every case the tubercle bacillus, as determined by inoculation experiments (*i.e.* at a temperature not exceeding 68° C.). (2) When milk is exposed under conditions which would enable a pellicle to form on the surface, the tubercle bacillus may resist the action of heat at 60° C. for considerable periods. (3) In order to thoroughly pasteurise milk without injuring its creaming properties or consistency, it should be heated in closed pasteurisers for a period of not less than twenty minutes at 60° C. Under these conditions, it is certain that disease bacteria such as the tubercle bacillus will be destroyed without the milk or cream being injured in any way."

There has been considerable diversity of opinion concerning the ethnic affinities of the Slavs, and Zaborowski returns to the subject in a recent number of the *Bulletins et Mémoires de la Société d'Anthropologie* (5), I., 1900. His view is that the Slavs belong to the same race as the Celts of French anthropologists, that is, being brunet brachycephals, they are members of the Alpine race. Their original home was that which is still occupied by the southern Slavs between the Danube and the Adriatic, and they were allied to the inhabitants of the Terramara of Emilia. The northern Slavs migrated along the valley of the Vistula and reached the shores of the Baltic, where they developed a civilisation and introduced in this region the practice of burning their dead, which was previously unknown there; they also brought with them metals and glass.

Wherever the Slavs migrated they introduced the custom of incineration, and carried with them the characteristic metal head-rings, the ends of which terminated in sigmoid curves (Hackenringe). The settlement of the Venede on the Baltic dates back to the fourth century, B.C. The Baltic Slavs were profoundly affected by the expansion of the Germans about the beginning of our era, but apparently not till the eighth century A.D., did the slavs colonise Northern Russia.

MR. R. SHELFORD, of the Sarawak Museum, has sent us a copy of his paper in the October number of the *Ibis*, describing the arrangement of the down and plumage in the embryos and young of *Centropus sinensis*—an aberrant cuckoo. Certain differences from the arrangement obtaining in the allied *C. celebensis* are noticed.

THE sixth fasciculus of vol. v. of the Memoirs of the Boston (U.S.) Society of Natural History is devoted to an elaborate memoir by Mr. R. P. Bigelow on the anatomy and development of the medusa known as *Cassiopea xamachana*. In common with the allied *Polyclonia frondosa*, this is a form specially modified for a sedentary existence in shallow water among mangrove roots.

WE have received the Report of the Museums Association for 1900, containing the account of the meeting held at Canterbury in July last under the presidency of Dr. Henry Woodward. It is satisfactory to learn that this useful association is in such a flourishing condition that it has to consider how best to spend its surplus income. The Report includes the President's address, together with twelve papers and various notes. Mr. F. A. Bather gives specimens of descriptive museum labels for certain groups of echinoderms, but the extreme technicality of these suggests that they are suited for a zoological text-book rather than for the ordinary public. A heading like "CRYPTOBLASTUS, E. AND C," is calculated to mystify rather than enlighten the uninitiated. In his address, the President dwells on the difficulty of amalgamating the recent and fossil zoological collections in the British Museum owing to the constitution of the Staff.

THE abstract of a paper by Dr. W. H. Gaskell on the origin of the eyes of vertebrates and the meaning of the second pair of cranial nerves appears in the November issue of the *Proceedings* of the Anatomical Society. After stating that the ancestor of the vertebrates possessed a pair of diverticula from the fore part of the alimentary canal with which the ganglia of the retina and the optic stalks of the lateral eyes were connected, the author pointed out that such a pair of blind diverticula exist in generalised crustaceans, such as *Branchipus* and *Apus*, adding that there is a connection between these diverticula and the retinal ganglion. It is therefore assumed that similar structures existed in the extinct trilobites. From this and other evidence it is inferred that the origin of the vertebrate eye is traceable to an animal derived from the trilobite stock, such as was abundant when the fish-like cephalaspids made their appearance.

THE horary values of the magnetic elements (declination and horizontal force) at Copenhagen, in the years 1895–1896, are given by M. Adam Paulsen in the *Annales* de l'Observatoire magnétique de Copenhague, just received from the Denmark Meteorological Institute, of which M. Paulsen is director.

THE Sanitary and Economic Association, Ltd., Gloucester, have sent us a pamphlet published by them for the purpose of promoting the economy of coal, the abatement of smoke, and the diffusion of an elementary knowledge of the first principles of warming and ventilating generally.

PROF. S. P. THOMPSON'S interesting story of "Michael Faraday: His Life and Work," published in the Century Science Series, is now available in the popular edition at the low price of half-a-crown. The book was reviewed in NATURE of June 8, 1899 (vol. lx. p. 123). Messrs. Cassell and Co. are the publishers.

MESSRS. SAMPSON LOW, MARSTON AND CO. have published the sixth edition of Mr. N. E. Yorke-Davies' little book on "Health and Condition in the Active and the Sedentary." The book contains a clear statement of the laws of health, with special reference to the dietetic treatment of ailments due to errors in eating and drinking.

ONE of the most remarkable catalytic agents recently discovered is metallic nickel, reduced from its oxide at a low temperature. Two or three years ago MM. Sabatier and Senderens showed that this metal is capable of causing the direct combination of hydrogen with ethylene and acetylene, ethane being formed in both cases. In the current number of the *Comptes rendus* they now show that reduced nickel is a very active catalytic agent, so far as the addition of hydrogen is concerned surpassing even spongy platinum. Thus a mixture of hydrogen and benzene vapour, passed over reduced nickel at about 200° C., readily gives hexahydrobenzene, no benzene escaping conversion if the hydrogen is in excess. The reaction appears to be a general one, since the homologues of benzene behave similarly; nitrobenzene is reduced to aniline.

THE phenomenon of birotation of the sugars has given rise to a considerable amount of work without any very definite results being obtained. In the current number of the *Zeitschrift fur physikalische Chemie* there is a paper, by Dr. Yukichi Osaka, on the birotation of *d*-glucose, which throws much light upon this subject, and forms an interesting application of the dissociation theory of solution. From the velocity constants of the change of rotation of *d*-glucose, both alone and in presence of acids, bases and neutral salts, it is shown that this sugar acts as a weak acid, the velocity of the change of rotation being proportional to the concentration of the hydroxyl ions, and to the square root of the concentration of the hydrogen ions.

THE additions to the Zoological Society's Gardens during the past week include a Sykes's Monkey (*Cercopithecus albigularis*) from East Africa, presented by Mr. J. Coombes; two Black-necked Swans (*Cygnus nigricollis*) from Antarctic America, a Yellow-rumped Parrakeet (*Platycercus flaveolus*) from Australia, three Blue-fronted Amazons (*Chrysotis aestiva*) from South America, deposited.

OUR ASTRONOMICAL COLUMN.

VARIATIONS IN THE MOTION OF THE TERRESTRIAL POLE.—In the *Astronomical Journal* (vol. xxi. No. 489), Prof. S. C. Chandler investigates the data available for determining the changes in the annual elliptical component of the polar motion. References to these changes have been previously made in *A. J.* Nos. 422 and 446, but no decisive conclusions could then be made. The data are taken from the records at Pulkowa, Leyden, Washington, Berlin, Cambridge and Madison, and are grouped for two epochs, 1865, 1883. From each series the effect of the 427-day term of the latitude variation is eliminated after correction to a uniform value of the aberration constant and stellar parallax; from the residuals the constants of the annual term of the latitude variation are found, and finally, by combining these constants for all the series at each epoch, the elemen of the ellipse are computed for 1865 and 1883.

The present article considers all records prior to 1890, and the result indicates that the line of apsides is revolving from east to west, or in a direction contrary to that of the pole in its orbit, in a long period of some 75 years—*i.e.* at a rate of about 5° annually; also that the length of the annual period oscillates about its mean value, the fluctuations having a long periodical character, with a cycle of about 60 years.

DEFINITIVE ELEMENTS OF THE ORBIT OF COMET 1898 VII.—Nos. 3684, 3685 of the *Astronomische Nachrichten* are devoted to an exhaustive discussion, by Mr. C. J. Merfield, of Sydney, of the data recorded for the comet discovered by Mr. Coddington at the Lick Observatory on June 11, 1898. Some 400 observations are utilised, the largest series being those made by Mr. Tebbutt at Windsor, New South Wales.

Epoch of Osculation 1898 *June* 21.

T = 1898 Sept. 14·0442056 G.M.T.

$$\left.\begin{array}{l} \omega = 233^\circ\ 15'\ 18''\cdot66 \\ \Omega = 74\ \ 0\ \ 58\cdot17 \\ i = 69\ \ 56\ \ 0\cdot37 \end{array}\right\} 1900\cdot0$$

$$\log q = 0\cdot2308587.$$
$$\log e = 0\cdot0004487.$$
$$e = 1\cdot0010336.$$

OBSERVATIONS OF EROS.—Several observers are now commencing to publish their lists of measures of the planet Eros, made during the recent opposition. In the *Astronomische Nachrichten* (Bd. 154, No. 3683), Prof. A. Abetti gives a long list of measures taken during July, August, September, October and December 1900 at Arcetri-Firenze.

M. J. Pidoux also contributes a series obtained during October and November 1900 at Geneva, and Signor A. Antoniazzi others during July and August 1900 at Padova.

PHOTOGRAPHIC CATALOGUE OF POLAR STARS.—The first issue of the *Publications of the Vassar College Observatory*, U.S.A., contains a catalogue of sixty-five stars within one degree of the North Pole, reduced by Miss C. E. Furness from photographs obtained with the 13-inch Helsingfors astrographic refractor. A discussion of the results in a manner suggested by Prof. Jacoby, of Columbia University, led the conclusion that, within the limits of the plates—2° square—no optical distortion was to be detected.

AUDIBILITY OF THE SOUND OF FIRING ON FEBRUARY 1.

ON Friday last, between three and four in the afternoon, the body of our lamented Queen was conveyed from Cowes to Portsmouth past a fleet consisting of some of the finest battleships of the world. The minute-guns fired from these vessels during the passage of the funeral procession were clearly heard at great distances from Spithead; for, from the regularity of the discharges, there can be little doubt as to the origin of the reports.

We have received several letters referring to the sounds heard at various places. Prof. E. B. Poulton, F.R.S., writes as follows from Youlbury, Boar's Hill, near Oxford:—

"During the interval between three and four o'clock on the afternoon of Friday, February 1, many people on this hill, about 520 feet above sea-level, including Mr. Arthur J. Evans and I, heard the sound of distant guns. The period over which the sounds were heard, the direction from which they appeared to come, the mode of their occurrence in groups separated by intervals of silence, led us to believe that they were the guns of the fleet ranged between Cowes and Portsmouth, and that each group of sounds represented the salute of a single ship as it was passed by the Royal Yacht. Judging from an old atlas the distance appears to be about sixty-seven miles in a straight line. The afternoon was bright and sunny and the air very still. The sounds could be distinctly heard in the house with closed windows. Out of doors they were really impressive. It is probable that other records will reach you, indicating that they were noticed at much greater distances."

Prof. F. J. Allen and Mr. C. Thwaites heard the reports very distinctly at Sutton, Surrey, which is about sixty miles from Portsmouth, and the latter states that the windows of a house were slightly shaken with each discharge.

Several letters from correspondents who heard the sounds have appeared in the *Times*, the *Standard* and the *Daily News*. Towards the east, the booming of the guns was distinctly heard at Beachy Head (60 miles from Spithead), near Brightling (69 miles) and Woodchurch (84 miles); towards the east-north-east, near Tunbridge Wells (66 miles); towards the north-east, at Wallington (59 miles), Croydon and Richmond Hill (62 miles), and Bexley (75 miles); towards the north-north-east, near King's Langley (74 miles); and towards the north, at Marcham (near Abingdon, 64 miles), Great Missenden (69 miles), Oxford (70 miles), Witney (73 miles), and Leighton Buzzard (84 miles). The concussion was sometimes strong enough to shake windows at Wallington, Richmond Hill and Great Missenden. Near Brightling, cock-pheasants crowed as they do during a thunderstorm. As a rule, there appears to have been little or no wind to interfere with the propagation of the sound-waves.

JUPITER AND HIS MARKINGS.

JUPITER is now visible as a morning star, and observers have resumed their investigations of his surface markings. The coming opposition on June 30 will not be a favourable one for telescopists in Europe, as the planet will be in about 23 degrees of south declination, and therefore at a very low altitude.

The lingering relics of the great red spot, situated within the hollow in the south side of the southern equatorial belt, will probably be a difficult feature in the circumstances. But it should be carefully looked for, and its times of transit across the central meridian of the planet noted as frequently as possible. These will occur during February, about 80 minutes after the times given for the zero meridian (System II.) by Mr. Crommelin in his ephemerides published in the *Monthly Notices* for December 1900. Whenever the red spot itself cannot be distinguished, it will be advisable to take the time of transit of the hollow in the belt, which is a very easy object. In recent years the rotation of the spot and hollow has exhibited a slow decrease of speed, amounting to about one-tenth of a second annually. In 1896 the period was 9h. 55m. 41·3s., in 1900 9h. 55m. 41·8s. On February 15, 1901, the longitude of the spot will be about 48°, if the retardation has continued. Its easterly drift will bring it into longitude 51°·5 on June 15, 1901, and 61°·5 on June 15, 1902.

With regard to the equatorial spots, these have shown a mean motion of about 9h. 50m. 24·1s. during the past three years, and this is about six seconds shorter than the period adopted for System I. in the ephemerides above referred to.

The study of Jupiter during the present year may have a special significance, for it is likely to throw an important light upon the question whether or not certain features on the disc are recurrent at pretty regular intervals. There is a belt in about 23° north latitude which displayed some remarkable outbreaks of spots in 1869, 1880 and 1890, and a similar phenomenon is now again due if such outbreaks are periodical and owe their origin to some disturbing action repeated on the planet at intervals of about a decade. The features alluded to move more rapidly than any other markings observed on the disc. The same, north temperate, belt is often marked with small dark spots or condensations, but these travel with normal velocity and differ little from the rate of the red spot. There is another current in this region conforming with a period of 9h. 56m., which is probably slower than any other Iovian current. In the southern hemisphere, south of the red spot, there are two well-pronounced streams translating their various markings along at rates of 9h. 55m. 19s. and 9h. 55m. 7s. for a complete circuit.

Among other details offered by the planet may be mentioned the colours of the belts and their relative intensity and distribution over the disc. The value of continuous observation of the forms and motions of the markings in various latitudes is very great. It is only by collecting a mass of results during many consecutive years that proper investigation can be made and the various changes in progress assigned their proper periods. Until quite recently observations were somewhat irregular and altogether insufficient for a complete discussion of the phenomena. During the coming opposition observers in the southern hemisphere will have the planet well placed, and ought to be able to supply any deficiencies in the results obtained at northern observatories.

W. F. DENNING.

AGRICULTURE IN THE WEST INDIES.

THE third annual Agricultural Conference, under the presidentship of Dr. Morris, Commissioner of the Imperial Department of Agriculture for the West Indies, was held in the Legislative Chamber, Bridgetown, Barbados, on January 5. Besides Dr. Morris, the president of the Conference, and some fifty official, scientific, agricultural and educational representatives from the various West Indian colonies, there were present the Acting Governor, a large number of officials and representatives of the Legislature, and visitors.

After the usual preliminary formalities, Dr. Morris delivered his presidential address, which afforded a clear summary of the progress made by the Department of Agriculture for the preceding year and enumerated the questions which this Conference would be invited to discuss. The work of the officers of the Department during the preceding year covered a wide range. In the domain of the sugar industry it comprised researches to improve the sugar cane, experiments to reduce the cost of cultivation, efforts to advance the erection of central factories and researches upon insect and fungoid diseases, including an exhaustive investigation and monograph by the entomologist, Mr. H. Maxwell Lefroy, on the moth borer (*Diatraea saccharalis*).

Besides the work of the Department on the cacao industry and the lime industry, an attempt had been made, with prospects of success, to establish the growing of early potatoes for the English market; a small but promising onion industry had been established in Antigua, and there was every reason to believe that the fruit trade between Jamaica and the United Kingdom would receive an enormous impetus by the subsidising a direct fruit steamer service between the Mother Country and that Colony.

Agricultural education had occupied a large share of attention; the teachers of the elementary schools of nearly all the colonies were being trained by courses of lectures and demonstrations to teach the elementary principles of agriculture in their schools; seven exhibitions, of value varying from 10*l*. to 75*l*. per annum, had been awarded to pupils from first grade (public) schools in the various islands which were tenable at Harrison College, where a two years' course in agricultural science was given by the Science Department, Barbados. Agricultural industrial schools had been opened at St. Vincent and Dominica.

Nine botanic stations were now supported by Imperial funds, and a large number of experimental stations had been instituted in the various colonies, where experiments were being systematically carried out on questions connected with the sugar cane and all the other products of the West Indies.

Agricultural shows had been successfully carried out in three of the islands under the auspices of the Department, which had contributed 350*l*. in prizes and more than one hundred diplomas of merit.

The address concluded with some remarks upon the subject of the treatment of diseased plants, and upon the advisability of legislation with a view to prevent the introduction of plant disease into colonies from without, and to provide for the eradication of disease within the colonies.

The following papers were read during the Conference:—

Sugar Industry: Recent experiments with seedlings and other canes, by Prof. d'Albuquerque and Mr. J. R. Bovell (Barbados), and a short history of seedling canes in Barbados, by Mr. J. R. Bovell (Barbados), followed by a discussion in which representatives from all the colonies took part; cane farming in Trinidad, by Prof. Carmody (Trinidad); insect pests of sugar cane, by Mr. H. Maxwell Lefroy, entomologist of the Department; fungoid diseases of the sugar cane, by Mr. Albert Howard (Barbados).

Educational: Agricultural education and its place in general education, by Rev. Canon Simms (Jamaica); teaching the principles of agriculture in elementary schools, by the Hon. T. Capper (Jamaica); results of ten years' experience with compulsory enactments in the Leeward Islands, by Mr. C. M. Martin (Leeward Islands).

General:—Legislation to control bush fires, by Dr. H. Nicholls (Dominica); the treatment of soils in orchard cultivation in the tropics, by the Hon. Francis Watts (Leeward Islands); on rubber planting in the West Indies, by Mr. J. H. Hart (Trinidad); pine-apple cultivation at Antigua, by the Hon. Francis Watts (Leeward Islands); the marine resources of the West Indies, by Dr. J. E. Duerden (Jamaica); bee-keeping, by Mr. W. K. Morrison, the acting bee expert of the Department; the cultivation of onions at Antigua, by Mr. Wm. Sands; zebra cattle in Trinidad, by Mr. J. H. Hart and Mr. C. W. Meaden; artificial drying of cacao, by Mr. G. Whitfield Smith; and experiments on the treatment of insect pests in 1900, by Mr. H. Maxwell Lefroy. These papers, together with the discussions that followed them, will be produced in the *West Indian Bulletin*, the official organ of the Imperial Agricultural Department for the West Indies.

The Chemical Section of the Conference, adjourned from the previous year, drew up a report dealing chiefly with uniformity of records in reports upon sugar cane experiments. The Educational Section held a meeting to consider matters connected with the teaching of agriculture in elementary and first grade schools, including the compilation of teachers' handbooks.

J. P. D'ALBUQUERQUE.

NATIONAL ASPECTS OF SCIENTIFIC INVESTIGATION.

AS a rule, the recognition of scientific work by the State is the last matter with which men of science concern themselves. Their work is sufficient for them, and they are content with the results obtained, whether appreciated or not at the proper value to the commonwealth; they are the victors, but they leave the spoils to others. Most true investigators are inspired by this unselfish sentiment, rather than by the desire for personal profit, and all they ask for is the adequate provision of means for research. Even this request is not urged with the persistency necessary to produce effect. It must be remembered that the general public, as well as the persons who have it in their power to encourage investigation by granting subsidies and extending other facilities, do not understand the fundamental importance to the nation of contributions to the store of natural knowledge. When they appreciate the fact that scientific work furnishes the motive power of industrial progress, they will regard it in a more serious and liberal spirit than at present. For this reason no opportunity should be lost of reminding the State of its duties and responsibilities as regards scientific work, the claims of which are not urged with sufficient force by the men engaged in it. Scientific societies and associations in Great Britain interest themselves in the advancement of natural knowledge, but it might be well occasionally to hold a meeting for the purpose of stating some of the relationships between research and national welfare. Such a meeting was held recently at Baltimore, by the American Society of Naturalists, and addresses on the attitude of the State toward scientific investigation were given by Prof. H. F. Osborn, Prof. W. Bullock Clark, Dr. L. O. Howard, Dr. B. T. Galloway and Prof. W. T. Sedgwick. The following extracts from the remarks made upon this occasion are abridged from the report in *Science*.

In the course of the remarks with which the discussion was opened, Prof. H. F. Osborn said:—

A fair criterion of intelligence in the government of a country is afforded by an examination of its annual budget. There is first the provision for a certain number of expenditures which are purely conservative, because the State must maintain itself, it must defend itself, it must support a large class of office-holders who are more or less useful. These expenditures may be wisely and honestly made, but they largely go to waste; they are either immediately productive or altogether non-productive. On the other hand, there are expenditures in the nature of investments, looking to the future and characterising the most far-sighted statesmanship. Conspicuous among these are the funds invested in education and science.

Said Helmholtz in 1862: "In fact men of science form, as it were, an organised army, labouring on behalf of the whole nation, and generally under its direction and at its expense, to augment the stock of such knowledge as may serve to promote industrial enterprise, to increase wealth, to adorn life, to improve political and social relations, and to further the moral development of individual citizens. After the immediate practical results of their work we forbear to inquire; that we leave to the uninstructed. We are convinced that whatever contributes to the knowledge of the forces of nature or the powers of the human mind is worth cherishing, and may, in its own due time, bear practical fruit, very often where we should least have expected it."

Of European countries Germany places in its budget the largest productive investments of this kind; France is not far behind, England is perhaps fourth and affords a conspicuous

example of blindness and fatuity in the matter of unproductive investment; she has, it is true, established textile schools, but has not sufficiently supported technical schools; the cost of a single battleship would establish four splendidly equipped technical schools; England secures the ship and postpones the construction of the schools. All this is through no fault of her prophets of science, who have been as persistent as Jeremiah in foretelling the consequences which are sure to follow.

Yet England gave Darwin his schooling upon the *Beagle;* and Huxley secured his upon the *Rattlesnake.* As a seafaring nation, marine zoology appeals to her imagination, and the single notable departure from her short-sighted policy in the encouragement of pure science is the magnificent service she has rendered in the *Challenger* expedition. Our own Dana was trained upon the Wilkes expedition; the French Government equipped the *Talisman;* the German Government is supporting the highly successful cruise of the *Valdivia* and its publications under Chun; the U.S. Government has a permanent exploring vessel in the *Albatross.*

In this rivalry of foresightedness the German and French Governments have been our keenest competitors both on sea and land, and have probably surpassed us in the recognition of the ultimate economy of pure research. Germany's most admirable recent action is the subvention of Prof. Abbe for his investigations upon optics. Abbe's work was not in the nature of invention, but of research and discovery in the highest sense, resulting in the production of an illuminating stage, apochromatic and achromatic immersion lenses, which have fairly revolutionised biology. What we owe to these lenses in a theoretical sense could not be stated in a single volume, and the economic value is equally immeasurable.

The distinctive feature of pure science is that it is not remunerative; the practical rewards and returns are not the immediate objects in view. On the other hand, the work of Tyndall and Pasteur on fermentation, pursued in the first instance for its own sake, has come to have an economic importance which is simply incalculable.

American legislators have lent a willing ear to the advice of wise men. What we now enjoy we owe mainly to the counsels of Joseph Henry, Spencer F. Baird and G. Brown Goode. And I may call attention here to a thought which will be expanded presently, namely, that the secret of the success of these men is to be found in their enthusiasm, unselfishness and lofty scientific and personal character. When we consider the liberal appropriations made year after year for the United States Geological Survey, the nobly equipped station at Wood's Holl, the purely scientific work which is now being supported by many States and municipalities, there is abundant cause for congratulation. . . .

Prof. W. Bullock Clark dealt chiefly with the power of legislators, cooperation between national bureaux and University institutions and the preparation of men by universities for State work. He said :—

It may perhaps be desirable to examine for a moment the reason why scientific investigation is not and cannot be self-supporting. This may be found in the fact that the great majority of scientific researches have no immediate commercial value and as commodities cannot find a speedy or, in most instances probably, even a prospective market. We all know of many investigations, begun without thought of pecuniary advantage, that have ultimately produced practical results of the greatest importance. Instances might be cited of investigations the value of which were not apparent until a generation or more had passed, as, for example, palæontological researches which have laid the foundation for the correlation of deposits of great economic value. The support of such investigations must be looked upon as investments for the State which no far-sighted statesman will ignore.

We find that ever since the establishment of universities and seminaries widely over Europe in the fourteenth and fifteenth centuries, the civilised countries of the world have recognised in one form or another the relation of the State to scientific investigation. Not only the great nations of the world, but oftentimes the small and relatively poor countries like Belgium and Switzerland, as well as the smallest of our own commonwealths, have frequently provided liberally for the support of scientific research. This has been accomplished through the publicly endowed educational institutions, through the public museums and through the special bureaux of the Government.

Too frequently scientific investigation has held a subordinate place in both the publicly and privately endowed institutions, their chief functions being either educational or commercial. The purpose of the schools and universities is primarily in most instances the instructing of youth in the already acquired results of scientific research rather than the fostering of investigation for itself, although the latter as a secondary consideration often holds a prominent place in the larger institutions of learning. The museums and scientific bureaux are, like our great universities, centres of research, without the exactions of teaching, where continuous investigation can be pursued under most favourable conditions, although here again either educational or commercial considerations for the most part ostensibly control. That this is not always the case is cause for congratulation, and the support of research directly for itself without other, and oftentimes false, claims is becoming yearly a more fully recognised fact.

It is interesting for us who are Americans to know that the claims of science received recognition at the very inception of our Government, for we find that George Washington in his first message to Congress stated: "Nor am I less persuaded that you will agree with me in opinion that there is nothing more deserving your patronage than the promotion of science and literature. Knowledge in every country is the surest basis of public happiness. In one in which the measures of government receive their impressions so immediately from the sense of the community as ours it is proportionately essential." How well that early advice has been carried out by the statesmen of later days under the wise counsels of Henry, Baird, Goode and their successors, Prof. Osborn has already shown. . . .

The various bureaux and divisions of the U.S. Department of Agriculture, the U.S. Geological Survey and the U.S. Coast and Geodetic Survey are all manifesting a broad spirit of helpfulness that is being met by the State and university institutions. The possibilities of an extension of this co-operation between Nation, State and University promise well for the widening of the bounds of scientific investigation in this country. It is indeed a hopeful sign when we see the scientific men of the nation, whatever their affiliations, working together with mutual interest and respect. May it presage the dawn of a still brighter day in American science.

Dr. L. O. Howard spoke more particularly upon the ultimate practical importance of pure scientific work from the point of view of applied entomology, and the preparation of men for the scientific work of the State. He said :—

It is upon work in pure science that the entire superstructure of economic entomology has been built, and workers in applied science are constantly making use of the results of the labours of workers in pure science. The practical outcome, however, of the labours of the workers in pure science is indirect, while the practical outcome of those who work in the economic applications of science is direct. In any emergency the direct method is the one which is immediately productive of practical results. The study of economic entomology is a study of facts which will enable us to meet one great and widely extended emergency. It must be conducted by the direct method, and the reason why this country stands in advance of the rest of the world in this application of science is because we are a practical people and have adopted the direct method. There can be no doubt, however, that it is necessary for the most successful economic worker to have had a sound training in pure science. . . .

Men in charge of university departments of scientific work should keep closely in touch with the Government work along similar lines. They should be encouraged to do this by the Government. Government should employ their services wherever they can be of use, and such cases are numerous. They themselves should be able, with the intimate knowledge acquired by official association or by close investigation of Government work, to lay out lines of study which will fit their students to take a hand in Government work. In many cases, of course, this cannot be thoroughly done in university laboratories at the present time. . . .

The U.S. Department of Agriculture is the first of the Government bureaux which does economic zoological work. Good research work and initiative in investigation are encouraged. Nothing could be more ideally perfect than the relation between the present head of the Department of Agriculture and his scientific corps. Four years ago he announced his policy in this regard in conversation with one of his scientific chiefs in the following words :—"I am here to facilitate your work, not to dictate to you. Make your plans, conduct your investigations,

and I will help you with all my strength, but I shall hold you responsible for results." Scientific men should honour James Wilson for the introduction of this novel principle in the administration of a Government scientific bureau . . . .

The old popular idea of a scientific man—that he lacks what is called "common sense," that he is unpractical—is an unfortunate estimate gained from unappreciative observation of workers in pure science, but it no longer holds. Henry, Agassiz, Baird—all men of affairs, now gone—did much to change this popular estimate, and the host of brilliant men who have succeeded them—men of high scientific rank, who control the destinies and shape the policies of great institutions, and who turn out work of great and important practical value—have demonstrated beyond the slightest doubt that scientific men are the broadest men of affairs, that they are practical men, and that they are fit to be leaders, not only in thought, but in action.

It is doubtful whether any Government in existence does as much for the encouragement and development of science as does our own. This has repaid her a thousandfold, and the sound judgment of the American people and their patriotic pride in national attainment will effect a steady increase in governmental support of scientific work in spite of temporary checks. With scientific men, however, must come the initiative. They must point out the needs and the ways and means by which these needs must be supplied.

Dr. B. T. Galloway spoke as follows:—

Is it not true that the attitude of the State toward science and scientific research is at all times greatly influenced by the shaping of public sentiment through the work of scientific men themselves? This is a practical age, and in America especially the tendency is more and more to give a practical trend to almost every line of research. We find, therefore, as a matter of fact, that there is a general lack of interest in, and support of, matters having to do with pure science alone, while on the other hand all questions having practical application, and even those in which the practical end is remote, are received with commendable liberality. Taking the field of botany, for example, it would be difficult, if not impracticable, to secure support for the preparation and publication of purely floristic monographs, unless it could be pretty clearly shown that such a project had some practical end in view.

In so far, therefore, as the attitude of the State towards all work of this nature is concerned, there is a great deal of conservatism to be overcome, and this conservatism is especially pronounced where pure science is brought strongly to the front. The reason for this is not far to seek, for its roots lie imbedded in the selfishness of human nature, which, acting through organisation in the shape of government, sees, or thinks it sees, in the aggressiveness of science a menace to existing institutions in some form or other. While science in its nature is aggressive, the men who do most to advance it often lack aggressiveness, and for this reason the far-reaching effect of science as an educational factor at the present time is not fully understood or appreciated.

This brings me more particularly to the main question I wish to raise in this discussion, namely, what should be the attitude of the scientific man toward the cause he represents. I am strongly of the opinion that he owes it to himself and to his work to put forth every legitimate effort to advance the interests of the cause. He should, of course, keep constantly before him the fact that to bring honour and credit to the work he must recognise the duties of life. This will not allow him, however, to sit calmly down and wait for the material things of the world to come to him. The men who have it in their power to aid him are too busy to go out of their way to render help unless that help is sought. . . .

With the distinctly utilitarian sentiment towards science, as pointed out, the question arises as to what stand should be taken by those charged with the guidance of the work with respect to shaping a general policy which will meet the demand for practical ends, and at the same time advance the cause of science to the fullest extent. Extremes must be avoided, for if the tendency is too strong toward pure science, opportunities will be lost through lack of support, and if toward ultra-utilitarianism, science itself will be endangered through the development of false views, erroneous statements and lack of judgment—rocks and reefs that must by all means be avoided. There is always a medium ground, however, where science and practice can each be made to help the other and each be the stronger for the support thus gained. This is the stand, I may say, that is now taken by those charged with most of the work conducted under the auspices of the Government, and which, during the past fifteen years at least, has resulted in a rapid development of all work along broad and safe lines. Most of the departments of the Government, wherein scientific work is carried on, owe their existence to a demand for greater knowledge on problems concerning the interests and welfare of the people. In the early days of this work too much attention was given to a mere diffusion of knowledge without regard to its source, and as a result of this original research did not receive the attention it deserved. In later years, however, the importance of research is becoming more and more appreciated, and as a result the work has increased in strength and now commands the respect it deserves. . . .

Prof. W. T. Sedgwick referred to the attitude of the people toward scientific investigation, and the hindrance inflicted upon scientific research by the tariff upon the requisite books and instruments. He added:—

I have been very much interested to hear the quotation from the "Message of Washington" urging upon our people the importance of promoting scientific investigation and research. I believe that the American people are, in increasing numbers, large-minded enough to look through and beyond the nearer every-day phenomena, and to realise that the promotion of discovery, no less than the promotion of learning, pays in every sense of the word. They perceive that it pays in the highest sense, in the enrichment of intellect and the cultivation of faculty. They perceive also that it pays in the utilitarian sense, in that it gives leadership among the nations of the earth in the applications of science which always follow hard upon the heels of discovery. Prof. Osborn has done well to point out that those nations which support research most liberally are those which are taking the lead in the industrial world to-day.

The barrier between pure and applied science is fading away, because they are constantly drawing nearer together and overgrowing one another. Pure science has given to applied science the fundamental elements of truth, perfection, knowledge and skill. Applied science, on the other hand, has developed so prodigiously as to react favourably upon pure science, furnishing for it rich sustenance and fertile soil in which it may flourish. An hour might well be spent in pointing out, not only the aid which pure science has given to applied science, but reciprocally the enormous development of pure science and scientific investigation wrought by applied science. It is one of the marvels of the day that many highly organised and differentiated industries, and even many of the coarser arts, find their narrow but sufficient basis of profit in the employment of the results of the latest and most advanced researches in pure science.

Our age has been called by one of the speakers who has preceded me a practical age, and so it is; but it is an age which has discovered in science the Promethean fire. The highest and truest utilitarianism of to-day is a generous cultivation of scientific investigation, not indeed for its own sake, but for the sake of the results which are sure to follow from it. As to the pursuit of science for its own sake, Prof. Osborn has, it seems to me, used a happy illustration in referring to the scientific investigations of the Government as an investment rather than an immediate outlay for current expenses. As to pure science pursued strictly for its own sake, I think we may rather describe it as an investment from which we still expect ultimately some return. Science for its own sake is, after all, much like investment for its own sake; which has never been made, I fancy, even by the least practical of philanthropists.

For illustration of public appreciation of scientific research as a necessity for practical results, I may give an example. When in 1886 the newly organised State Board of Health of Massachusetts attacked scientifically the problem of protection of the purity of inland waters, they reported to the people of that State that in order to do the work required by the Legislature it would be necessary to inaugurate and prosecute special and novel investigations, and for this and other purposes they asked for an appropriation of 30,000 dollars. This sum was immediately and cheerfully granted by the people for this purpose and has ever since been continued, annually, with the result that the Massachusetts experiments are referred to with commendation and advantage by bacteriologists and engineers all over the world. Again, when it became clear that antitoxin for diphtheria had become a public necessity and its proper preparation a public duty, the same State Board of Health secured the services of one of the most distinguished

bacteriologists in the country, Prof. Theobald Smith, and requested him, not only to prepare antitoxin for the citizens of the State, but also to investigate the best methods of its preparation and preservation, besides other cognate and novel but pressing problems in the field of pure science. Here also the most thorough-going utilitarianism has proved to be scientific investigation pushed to its utmost limits. . . .

THE EFFECT OF PHYSICAL AGENTS ON BACTERIAL LIFE.[1]

THE fact that life did not exist upon the earth at a remote period of time, the possibility of its present existence as well as the prospect of its ultimate extinction, can be traced to the operation of certain physical conditions. These physical conditions upon which the maintenance of life as a whole depends are in their main issues beyond the control of man. We can but study, predict and, it may be, utilise their effects for our benefit. Life in its individual manifestations is, therefore, conditioned by the physical environment in which it is placed. Life rests on a physical basis, and the main springs of its energies are derived from a larger world outside itself. If these conditions, physical or chemical, are favourable, the functions of life proceed; if unfavourable, they cease—and death ultimately ensues. These factors have been studied and their effects utilised to conserve health or to prevent disease. It is our purpose this evening to study some of the purely physical factors, not in their direct bearing on man, but in relation to much lower forms in the scale of life—forms which constitute in number a family far exceeding that of the human species, and of which we may produce at will in a test-tube, within a few hours, a population equal to that of London. These lowly forms of life—the bacteria—belong to the vegetable kingdom, and each individual is represented by a simple cell.

These forms of life are ubiquitous in the soil, air and water, and are likewise to be met with in intimate association with plants and animals, whose tissues they may likewise invade with injurious or deadly effects. Their study is commonly termed bacteriology—a term frequently regarded as synonymous with a branch of purely medical investigation. It would be a mistake, however, to suppose that bacteriology is solely concerned with the study of the germs of disease. The dangerous microbes are in a hopeless minority in comparison with the number of those which are continually performing varied and most useful functions in the economy of nature. Their wide importance is due to the fact that they ensure the resolution and redistribution of dead and effete organic matter which, if allowed to accumulate, would speedily render life impossible on the surface of the earth. If medicine ceased to regard the bacteria, their study would still remain of primary importance in relation to many industrial processes in which they play a vital part. It will be seen, therefore, that their biology presents many points of interest to scientific workers generally. Their study as factors that ultimately concern us really began with Pasteur's researches upon fermentation. The subject of this evening's discourse, the effect of physical agents on bacterial life, is important not merely as a purely biological question, though this phase is of considerable interest, but also on account of the facts I have already indicated, viz. that micro-organisms fulfil such an important function in the processes of nature, in industrial operations, and in connection with the health of man and animals. It depends largely on the physical conditions to be met with in nature whether the micro-organisms exercise their functions, and likewise whether they die or remain inactive. Further, the conditions favouring one organism may be fatal to another, or an adaptability may be brought about to unusual conditions for their life. To the technologist the effect of physical agents in this respect is of importance, as a knowledge of their mode of action will guide him to the means to be employed for utilising the micro-organisms to the best advantage in processes of fermentation. The subject is of peculiar interest to those who are engaged in combating disease, as a knowledge of the physical agents that favour or retard bacterial life will furnish indications for the preventive measures to be adopted. With a suitable soil and an adequate temperature the propagation of bacteria proceeds with great rapidity. If the primary conditions of soil and an adequate temperature are not present, the organisms will not multiply; they remain quiescent or they die. The surface layers of the soil harbour the vast majority of the bacteria, and constitute the great storehouse in nature for these forms of life. They lessen in number in the deeper layers of the soil, and few or none are to be met with at a depth of 8–10 feet. As a matter of fact, the soil is a most efficient bacterial filter, and the majority of the bacteria are retained in its surface layers and are to be met with there. In the surface soil, most bacteria find the necessary physical conditions for their growth, and may be said to exist there under natural conditions. It is in the surface soil that their main scavenging functions are performed. In the deeper layers, the absence of air and the temperature conditions prove inimical to most forms.

Amongst pathogenic bacteria the organisms of lockjaw and of malignant œdema appear to be eminently inhabitants of the soil. As an indication of the richness of the surface soil in bacteria I may mention that 1 gramme of surface soil may contain from several hundred thousand to as many as several millions of bacteria. The air is poorest in bacteria. The favouring physical conditions to be met with in the soil are not present in the air. Though bacteria are to be met with in the air they are not multiplying forms, as is the case in the soil. The majority to be met with in air are derived from the soil. Their number lessens when the surface soil is moist, and it increases as the surface soil dries. In a dry season the number of air organisms will tend to increase.

Town air contains more bacteria than country air, whilst they become few and tend to disappear at high levels and on the sea. A shower of rain purifies the air greatly of bacteria. The organisms being, as I stated, mainly derived from the surface of the ground, their number mainly depends on the physical condition of the soil, and this depends on the weather. Bacteria cannot pass independently to the air, they are forcibly transferred to it with dust from various surfaces. The relative bacterial purity of the atmosphere is mainly, therefore, a question of dust. Even when found floating about in the air the bacteria are to be met with in much greater number in the dust that settles on exposed surfaces, *e.g.* floors, carpets, clothes and furniture. Through a process of sedimentation the lower layers of the air become richer in dust and bacteria, and any disturbance of dust will increase the number of bacteria in the air.

The simple act of breathing does not disseminate disease germs from a patient; it requires an act of coughing to carry them into the air with minute particles of moisture. From the earliest times great weight has been laid upon the danger of infection through air-borne contagia, and with the introduction of antiseptic surgery the endeavour was made to lessen this danger as much as possible by means of the carbolic spray, &c. In the same connection numerous bacteriological examinations of air have been made with the view of arriving at results of hygienic value. The average number of micro-organisms present in the air is 500–1000 per 1000 litres; of this number only 100–200 are bacteria, and they are almost entirely harmless forms. The organisms of suppuration have been detected in the air, and the tubercle bacillus in the dust adhering to the walls of rooms. Investigation has not, however, proved air to be one of the important channels of infection. The bactericidal action of sunlight, desiccation, and the diluting action of the atmosphere on noxious substances, will always greatly lessen the risk of direct aërial infection.

The physical agents that promote the passage of bacteria into the air are inimical to their vitality. Thus, the majority pass into the air, not from moist, but from dry surfaces, and the preliminary drying is injurious to a large number of bacteria. It follows that if the air is rendered dust-free, it is practically deprived of all the organisms it may contain. As regards enclosed spaces, the stilling of dust and more especially the disinfection of surfaces liable to breed dust or to harbour bacteria are more important points than air disinfection, and this fact has been recognised in modern surgery. In an investigation, in conjunction with Mr. Lunt, an estimation was arrived at of the ratio existing between the number of dust particles and bacteria in the air. We used Dr. Aitken's Dust-counter, which not only renders the dust particles visible, but gives a means of counting them in a sample of air. In an open suburb of London we found 20,000 dust particles in 1 cubic centimetre of air; in a yard in the centre of London about 500,000. The dust contamination we found to be about 900 per cent. greater in the centre of London than in a quiet suburb. In the open air of

[1] Discourse delivered at the Royal Institution by Dr. Allan Macfadyen, Director of the Jenner Institute of Preventive Medicine.

London there was, on an average, just one organism to every 38,300,000 dust particles present in the air, and in the air of a room, amongst 184,000,000 dust particles, only one organism could be detected.

These figures illustrate forcibly the poverty of the air in microorganisms even when very dusty, and likewise the enormous dilution they undergo in the atmosphere. Their continued existence is rendered difficult through the influence of desiccation and sunlight. Desiccation is one of nature's favourite methods for getting rid of bacteria. Moisture is necessary for their development and their vital processes, and constitutes about 80 per cent. of their cell-substance. When moisture is withdrawn, most bacterial cells, unless they produce resistant forms of the nature of spores, quickly succumb. The organism of cholera air-dried in a thin film dies in three hours. The organisms of diphtheria, typhoid fever and tuberculosis show more resistance, but die in a few weeks or months.

Dust containing tubercle bacilli may be carried about by air currents, and the bacilli in this way transferred from an affected to a healthy individual. It may, however, be said that drying attenuates and kills most of these forms of life in a comparatively short time. The spores of certain bacteria may, on the other hand, live for many years in a dried condition, *e.g.* the spores of anthrax bacilli which are so infective for cattle and also for man (wool-sorter's disease). Fortunately, few pathogenic bacteria possess spores, and, therefore, drying by checking and destroying their life is a physical agent that plays an important *rôle* in the elimination of infectious diseases. This process is aided by the marked bactericidal action of *sunlight*. Sunlight, which has a remarkable fostering influence on higher plant life, does not exercise the same influence on the bacteria. With few exceptions we must grow them in the dark in order to obtain successful cultures; and a sure way of losing our cultures is to leave them exposed to the light of day. Direct sunlight is the most deadly agent, and kills a large number of organisms in the short space of one to two hours; direct sunlight proves fatal to the typhoid bacillus in half an hour to two hours, to the diphtheria bacillus in half an hour to one hour, and to the tubercle bacillus in a few minutes to several hours. Even anthrax spores are killed by direct light in three and a half hours. Diffuse light is also injurious, though its action is slower. By exposing pigment-producing bacteria to sunlight, colourless varieties can be obtained, and virulent bacteria so weakened that they will no longer produce infection. The germicidal action of the sun's rays is most marked at the blue end of the spectrum, at the red end there is little or no germicidal action. It is evident that the continuous daily action of the *sun* along with *desiccation* are important physical agents in arresting the further development of the disease germs that are expelled from the body.

It has been shown that sunlight has an important effect in the spontaneous purification of rivers. It is a well-known fact that a river, despite contamination at a given point, may show little or no evidence of this contamination at a point further down in its course. Buchner added to water 100,000 colon bacilli per cubic centimetre, and found that all were dead after one hour's exposure to sunlight. He also found that in a clear lake the bactericidal action of sunlight extended to a depth of about six feet. Sunlight must therefore be taken into account as an agent in the purification of waters, in addition to sedimentation, oxidation and the action of algæ.

Air or the oxygen it contains has important and opposite effects on the life of bacteria. In 1861 Pasteur described an organism in connection with the butyric acid fermentation which would only grow in the absence of free oxygen. And since then a number of bacteria, showing a like property, have been isolated and described. They are termed anærobic bacteria, as their growth is hindered or stopped in the presence of air. The majority of the bacteria, however, are ærobic organisms, inasmuch as their growth is dependent upon a free supply of oxygen. There is likewise an intermediate group of organisms which show an adaptability to either of these conditions, being able to develop with or without free access to oxygen. Preeminent types of this group are to be met with in the digestive tract of animals, and the majority of disease-producing bacteria belong to this adaptive class. When a pigment-producing organism is grown without free oxygen its pigment production is almost always stopped. For anærobic forms N and H_2 give the best atmosphere for their growth, whilst CO_2 is not favourable and may be positively injurious, as, *e.g.*, in the case of the cholera organism.

The physical conditions favouring the presence and multiplication of bacteria in water under natural conditions are a low altitude, warmth, abundance of organic matter and a sluggish or stagnant condition of the water. As regards water-borne infectious diseases such as typhoid or cholera, their transmission to man by water may be excluded by simple boiling or by an adequate filtration. The freezing of water, whilst stopping the further multiplication of organisms, may conserve the life of disease germs by eliminating the destructive action of commoner competitive forms. Thus the typhoid bacillus may remain frozen in ice for some months without injury. Employment of ordinary cold is not, therefore, a protection against dangerous disease germs.

As regards *electricity*, there is little or no evidence of its direct action on bacterial life, the effects produced appear to be of an indirect character due to the development of heat or to the products of electrolysis.

Ozone is a powerful disinfectant, and its introduction into polluted water has a most marked purifying effect. The positive effects of the electric current may therefore be traced to the action of the chemical products and of heat. I am not aware that any direct action of the X-rays on bacteria has up to the present been definitely proved.

Mechanical agitation, if slight, may favour, and if excessive may hinder bacterial development. Violent shaking or concussion may not necessarily prove fatal so long as no mechanical lesion of the bacteria is brought about. If, however, substances likely to produce triturating effects are introduced, a disintegration and death of the cells follows. Thus Rowland, by a very rapid shaking of tubercle bacilli in a steel tube with quartz sand and hard steel balls, produced their complete disintegration in ten minutes.

Bacteria appear to be very resistant to the action of *pressure*. At 300-450 atmospheres putrefaction still takes place, and at 600 atmospheres the virulence of the anthrax bacillus remained unimpaired. Of the physical agents that affect bacterial life, temperature is the most important. Temperature profoundly influences the activity of bacteria. It may favour or hinder their growth, or it may put an end to their life. If we regard temperature in the first instance as a favouring agent, very striking differences are to be noted. The bacteria show a most remarkable range of temperature under which their growth is possible, extending from zero to 70° C. If we begin at the bottom of the scale we find organisms in water and in soil that are capable of growth and development at zero. Amongst these are certain species of phosphorescent bacteria which continue to emit light even at this low temperature. At the Jenner Institute we have met with organisms growing and developing at 34-40° F. The vast majority of interest to us find, however, the best conditions for their growth from 15° up to 37° C. Each species has a minimum, an optimum and a maximum temperature at which it will develop. It is important in studying any given species that the optimum temperature for their development be ascertained, and that this temperature be maintained. In this respect we can distinguish three broad groups. The first group includes those for which the optimum temperature is from 15-20° C. The second group includes the parasitic forms, viz. those which grow in the living body and for which the optimum temperature is at blood heat, viz. 37° C. We have a third group for which the optimum temperature lies as high as 50-55° C. On this account this latter group has been termed thermophilic, on account of its growth at such abnormally high temperatures—temperatures which are fatal to other forms of life. They have been the subject of personal investigation in conjunction with Dr. Blaxall. We found that there existed in nature an extensive group of such organisms to which the term thermophilic bacteria was applicable. Their growth and development occurred best at temperatures at which ordinary protoplasm becomes inert or dies. The best growths were always obtained at 55-65° C. Their wide distribution was of a striking nature. They were found by us in river water and mud, in sewage, and also in a sample of sea water. They were present in the digestive tract of man and animals, and in the surface and deep layers of the soil as well as in straw and in all samples of ensilage examined. Their rapid growth at high temperatures was remarkable, the whole surface of the culture medium being frequently overrun in from fifteen to seventeeen hours. The organisms examined by us (fourteen forms in all) belonged to the group of the Bacilli. Some were motile, some curdled milk, and some liquefied gelatin in virtue of a proteolytic enzyme.

The majority possessed reducing powers upon nitrates and decomposed proteid matter. In some instances cane sugar was inverted and starch was diastased. These facts well illustrate the full vitality of the organisms at these high temperatures, whilst all the organisms isolated grew best at 55°-65° C. A good growth in a few cases occurred at 72° C. Evidence of growth was obtained even at 74° C. They exhibited a remarkable and unique range of temperature, extending as far as 30° of the Centigrade scale.

As a concluding instance of the activity of these organisms we may cite their action upon cellulose. Cellulose is a substance that is exceedingly difficult to decompose, and is therefore used in the laboratory for filtering purposes in the form of Swedish filter paper, on account of its resistance to the action of solvents. We allowed these organisms to act on cellulose at 60° C. The result was that in ten to fourteen days a complete disintegration of the cellulose had taken place, probably into CO_2 and marsh gas. The exact conditions that may favour their growth, even if it be slow at subthermophilic temperatures, are not yet known —they may possibly be of a chemical nature.

Organisms may be gradually *acclimatised* to temperatures that prove unsuited to them under ordinary conditions. Thus the anthrax bacillus, with an optimum temperature for its development of 37° C., may be made to grow at 12° C. and at 42° C. Such anthrax bacilli proved pathogenic for the frog with a temperature of 12° C., and for the pigeon with a temperature of 42° C.

Let us in a very few words consider the inimical action of temperature on bacterial life. An organism placed below its minimum temperature ceases to develop, and if grown above its optimum temperature becomes attenuated as regards its virulence, etc., and may eventually die. The boiling point is fatal for non sporing organisms in a few minutes. The exact thermal death-point varies according to the optimum and maximum temperature for the growth of the organism in question. Thus for water bacteria with a low optimum temperature blood heat may be fatal; for pathogenic bacteria developing best at blood heat, a thermophilic temperature may be fatal (60° C.); and for thermophilic bacilli any temperature above 75° C. These remarks apply to the bacteria during their multiplying and vegetating phase of life. In their resting or spore stage the organisms are much more resistant to heat. Thus the anthrax organism in its bacillary phase is killed in one minute at 70° C.; in its spore stage it resists this temperature for hours, and is only killed after some minutes by boiling. In the soil there are spores of bacteria which require boiling for sixteen hours to ensure their death. These are important points to be remembered in sterilisation or disinfection experiments, viz. whether an organism does or does not produce these resistant spores. Most non-sporing forms are killed at 60° C. in a few minutes, but in an air-dry condition a longer time is necessary. Dry heat requires a longer time to act than moist heat: is requires 140° C. for three hours to kill anthrax spores. Dry heat cannot, therefore, be used for ordinary disinfection on account of its destructive action. Moist heat in the form of steam is the most effectual disinfectant, killing anthrax spores at boiling point in a few minutes, whilst a still quicker action is obtained if saturated steam under pressure be used. No spore, however resistant, remains alive after one minute's exposure to steam at 140° C. The varying thermal death-point of organisms and the problems of sterilisation cannot be better illustrated than in the case of milk, which is an admirable soil for the growth of a large number of bacteria. The most obvious example of this is the souring and curdling of milk that occurs after it has been standing for some time. This change is mainly due to the lactic acid bacteria, which ferment the milk sugar with the production of acidity.

Another class of bacteria may curdle the milk without souring it in virtue of a rennet-like ferment, whilst a third class precipitate and dissolve the casein of the milk, along with the development of butyric acid. The process whereby milk is submitted to a heat of 65° to 70° C. for twenty minutes is known as pasteurisation, and the milk so treated is familiar to us all as pasteurised milk. Whilst the pasteurising process weeds out the lactic acid bacteria from the milk, a temperature of 100° C. for one hour is necessary to destroy the butyric acid organisms: and even when this has been accomplished there still remain in the milk the spores of organisms which are only killed after a temperature of 100° C. for three to six hours. It will, therefore, be seen that pasteurisation produces a partial, not a complete sterilisation of the milk as regards its usual bacterial inhabitants. The sterilisation to be absolute would require six hours at boiling point. But for all ordinary practical purposes pasteurisation is an adequate procedure. All practical hygienic requirements are likewise adequately met by pasteurisation, if it is properly carried out and the milk is subsequently cooled. Milk may carry the infection of diphtheria, cholera, typhoid and scarlet fevers as well as the tubercle bacillus from a diseased animal to the human subject. For the purpose of rendering the milk innocuous, freezing and the addition of preservatives are inadequate methods of procedure. The one efficient and trustworthy agent we possess is heat. Heat and cold are the agents to be jointly employed in the process, viz a temperature sufficiently high to be fatal to organisms producing a rapid decomposition of milk, as well as to those which produce disease in man; this to be followed by a rapid cooling to preserve the fresh flavour and to prevent an increase of the bacteria that still remain alive. The pasteurising process fulfils these requirements.

In conjunction with Dr. Hewlett, I had occasion to investigate in how far the best pasteurising results might be obtained. We found that 60° to 68° C. applied for twenty minutes weeded out about 90 per cent. of the organisms present in the milk, leaving a 10 per cent. residue of resistant forms. It was found advisable to fix the pasteurising temperature at 68° C. in order to make certain of killing any pathogenic organisms that may happen to be present. We passed milk in a thin stream through a coil of metal piping, which was heated on its outer surface by water. By regulating the length of the coil, or the size of the tubing, or the rate of flow of the milk, almost any desired temperature could be obtained. The temperature we ultimately fixed at 70° C. The cooling was carried out in similar coils placed in iced water. The thin stream of milk was quickly heated and quickly cooled as it passed through the heated and cooled tubing, and, whilst it retained its natural flavour, the apparatus accomplished at 70° C. in thirty seconds a complete pasteurisation, instead of in twenty minutes, *i.e.* about 90 per cent. of the bacteria were killed, whilst the diphtheria, typhoid, tubercle and pus organisms were destroyed in the same remarkably short period of time, viz. thirty seconds. This will serve to illustrate how the physical agent of heat may be employed, as well as the sensitiveness of bacteria to heat when it is adequately employed.

Bacteria are much more sensitive to high than to low temperatures, and it is possible to proceed much further downwards than upwards in the scale of temperature, without impairing their vitality. Some will even multiply at zero, whilst others will remain alive when frozen under ordinary conditions.

I will conclude this discourse by briefly referring to experiments recently made with the most remarkable results upon the influence of low temperatures on bacterial life. The experiments were conducted at the suggestion of Sir James Crichton-Browne and Prof. Dewar. The necessary facilities were most kindly given at the Royal Institution, and the experiments were conducted under the personal supervision of Prof. Dewar. The action of liquid air on bacteria was first tested. A typical series of bacteria was employed for this purpose, possessing varying degrees of resistance to external agents. The bacteria were first simultaneously exposed to the temperature of liquid air for twenty hours (about − 190° C.). In no instance could any impairment of the vitality of the organisms be detected as regards their growth or functional activities. This was strikingly illustrated in the case of the phosphorescent organisms tested. The cells emit light which is apparently produced by a chemical process of intracellular oxidation, and the phenomenon ceases with the cessation of their activity. These organisms, therefore, furnished a very happy test of the influence of low temperatures on vital phenomena. These organisms when cooled down in liquid air became non-luminous, but on re-thawing the luminosity returned with unimpaired vigour as the cells renewed their activity. The sudden cessation and rapid renewal of the luminous properties of the cells despite the extreme changes of temperature was remarkable and striking. In further experiments the organisms were subjected to the temperature of liquid air for seven days. The results were again *nil*. On re-thawing the organisms renewed their life processes with unimpaired vigour. We had not yet succeeded in reaching the limits of vitality. Prof. Dewar kindly afforded the opportunity of submitting the organisms to the temperature of liquid hydrogen—about − 250° C. The same series of organisms was employed, and again the result was *nil*. This temperature is only 21° above that of the absolute zero, a

temperature at which, on our present theoretical conceptions, molecular movement ceases and the entire range of chemical and physical activities with which we are acquainted either cease or, it may be, assume an entirely new *rôle*. This temperature, again, is far below that at which any chemical reaction is known to take place. The fact, then, that life can continue to exist under such conditions affords new ground for reflection as to whether, after all, life is dependent for its continuance on chemical reactions. We, as biologists, therefore follow with the keenest interest Prof. Dewar's heroic attempts to reach the absolute zero of temperature; meanwhile his success has already led us to reconsider many of the main issues of the problem. And by having afforded us a new realm in which to experiment, Prof. Dewar has placed in our hands an agent of investigation from the effective use of which we who are working at the subject at least hope to gain a little further insight into the great mystery of life itself.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The election to the vacancy on the Council of the Senate, caused by the resignation of Bishop Ryle, will take place on February 8.

Mr. Stanley Gardiner has presented to the University an ethnological collection of 300 objects from the Maldives and Minikoi. The collection contains many valuable specimens.

Mr. W. N. Shaw, F.R.S., Secretary to the Meteorological Council, will give in the Cavendish laboratory a course of four lectures on the Physics of the Atmosphere, at 4.30, on February 7, 14, 21, and 28.

The Special Board for Biology recommend that the annual grant of 100*l.* shall be made by the University to Dr. Dohrn's Zoological Station at Naples for a further period of five years.

The Senate has sanctioned the obtaining of specifications and tenders for the erection of the Humphry Museum as a portion of the new Medical School Buildings.

THE following appointments have recently been made at the Jenner Institute of Preventive Medicine:—Dr. S. G. Hedin, of the University of Lund, Sweden, has been appointed head of the department of pathological chemistry; Mr. J. Beresford Leathes, lecturer in physiology at St. Thomas's Hospital Medical School, assistant in the same department; and Mr. W. J. Young, of the Owens College, Manchester, assistant in the chemical department. Drs. Moore, Petrie and Mackenzie have been elected to fill the three research studentships, the last-named gentleman being appointed to the Grocers' Company research studentship of the Jenner Institute.

AT the meeting of the London County Council on Monday, the Chairman announced that a letter had been received from Mr. Horniman, a member of the Council, offering on behalf of his father, Mr. Horniman, M.P., to the people of London a gift of great value, probably representing from 50,000*l.* to 100,000*l.* The letter was as follows:—"Dear Mr. Dickinson,—I have been empowered by my father, Mr. Horniman, M.P., who is now travelling in the East, to offer as a free gift to the people of London some fifteen acres of freehold land, together with the museum which has just been erected at the cost of about 40,000*l.* In it are placed the large art and natural history collections gathered by Mr. Horniman during the last twenty-five years. The property is situated close to Lordship Lane Station on the South Eastern and Chatham Railway and about three-quarters of a mile from Forest Hill Station on the London, Brighton and South Coast Railway. It consists of:—(1) A large house known as Surrey Mount and some nine and a half acres of pleasure grounds on the summit and slope of a hill commanding extensive views over south-eastern and south-western London. The site is a suitable one for a park or recreation ground, and has been open to the public during the summer months for four years. Over 200,000 persons visited it during fourteen months in 1897 and 1898. (2) The museum, a stone building 258 ft. long by 61 ft. wide, with a superficial area of 16,485 square feet. (3) Six residences, occupying some $5\frac{1}{2}$ acres of ground, now let on leases of diverse terms and bringing in an income of about 600*l.* per annum, which could be used for the maintenance of the museum until the tenancies fall in, when the land could be added to the recreation ground and additions made to the museum if necessary. There is also a library of 5,500 volumes of travel, natural history, &c., and a Biblical library of 700 volumes, containing many early and rare editions. Notwithstanding the very inadequate way in which the collections were formerly housed, and the fact that they were open to the public on but two or three days a week, over 455,000 persons visited them in four years, averaging 660 per day in the last year. Mr. Horniman considers the time has now arrived when the museum and adjoining property will be more useful if vested in a public body, and he has much pleasure in offering the same to the London County Council as a place of public recreation and instruction. Beyond a condition that the museum and grounds are to be maintained in a proper condition and dedicated to the public for ever there are few or no conditions attached to the proposed gift, and I am sure there are none that the Council could not readily accept.—Yours faithfully, Emslie John Horniman." It was resolved that the offer be accepted, and that the thanks of the Council be conveyed to Mr. Horniman for his munificent gift.

SCIENTIFIC SERIAL.

Wiedemann's Annalen der Physik, January.—Double refraction in glass plates vibrating transversely, by W. Konig. In a long glass plate or rod vibrating transversely, there is at the nodes double refraction of a peculiar kind. This has been subjected to a detailed experimental study, and the results discussed fully from the theoretical point of view. The author has been successful in obtaining photographic records of these phenomena, copies of which accompany the paper.—On the tones produced by vibrating sheets of gas in flames, by V. Henson. A photographic study of vibrating flames.—On the absorption of light in coloured glass, by R. Zgismondy. The colour of a glass, and hence its absorption spectrum, depends, not only upon the nature of the colouring material present, but also upon the composition of the colourless glass itself. Experiments were therefore carried out with twelve glasses of different composition, varying from pure sodium and potassium silicate on the one hand to pure lead silicate on the other. Borax and fused boron trioxide were also examined. The colouring oxides included the oxides of copper, chromium, cobalt, nickel, manganese, iron and uranium. For these glasses the constant $A = E/gS$ was determined, where S is the specific gravity of the glass, g the number of milligrams of the colouring oxide per gram of glass, and E the extinction coefficient. The results are expressed graphically.—On the decrement of the electrical vibrations on the charging of condensers, by A. F. Sundell and Hj. Tallqvist. Although in many researches on damped vibrations the experimental figures for the time of oscillation agree well with those deduced theoretically, in the case of the decrement of these vibrations the agreement is either very rough, or there is no agreement at all. In the present series of experiments it is shown that if the necessary corrections are introduced, the experimental and theoretical results agree exactly.—On the melting point of gold, by L. Holborn and A. Day (see p. 330).—On the expansion of some metals at high temperatures, by L. Holborn and A. Day. The coefficients of expansion of platinum, palladium, silver, 20 per cent. platinum-iridium nickel, constantin, wrought iron and steel were determined for temperatures between 0° and 1000° C., where the melting-points allowed.—On the irregularity of the Weston cadmium element with 14·3 per cent. amalgam in the neighbourhood of 0° C., by W. Jaeger. It is shown that in the neighbourhood of 0° C. the irregular variations of this cell may amount to as much as two millivolts, although at 10° C. different elements agree to within a few tenths of a millivolt.—Communication to the knowledge of the phenomena in induction apparatus, by K. K. Johnson.—On surface tension, by H. Hulshof. The necessary existence of surface tension is deduced from the assumption of a continuous density variation in the capillary layer.—On the numerical relation between the two elasticity constants in isotropic media, according to the molecular theory, by W. Voigt.—On the electrical analogue to the Zeeman effect, by W. Voigt.—On the change of the form of vibration of light when propagated through a dispersive and absorbing medium, by W. Voigt.—Calculation of the conductivity of gases, by J. Stark.—A criticism of the mode of derivation of Wien's spectrum equation, by E. Jahnke, O. Lummer and E. Pringsheim.—On the history of telegraphy, by L. Lewin.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, January 17.—"The Thermo-chemistry of the Alloys of Copper and Zinc," by T. J. Baker, King Edward's School, Birmingham. Communicated by Prof. Poynting, F.R.S.

The heats of formation of a number of alloys of copper and zinc have been ascertained by measuring the difference between the heats of dissolution, in suitable solvents, of each alloy and of an equal weight of a mere mixture containing the metals in the same proportion.

The following solvents were employed :—

(*a*) An aqueous solution of chlorine.

(*b*) A mixture of ammonium chloride and ferric chloride solutions.

(*c*) A mixture of ammonium chloride and cupric chloride solutions.

The first solvent did not give satisfactory results, although it showed that the heat of dissolution of an alloy was sensibly less than that of the corresponding mixture.

Solvents *b* and *c* were found to be very suitable; the chemical actions concerned are simple reductions, and no gases are evolved.

Two series of experiments made on twenty-one alloys yielded very concordant results.

A sharply defined maximum heat of formation is found in the alloy containing 32 per cent. of copper, *i.e.* corresponding to $CuZn_2$. It amounts to 52·5 calories per gramme of alloy, or 10,143 calories per gramme-molecule. There is some evidence of a sub-maximum in the alloy corresponding to CuZn.

From these points there is a steady decrease in the heat of formation, both in the case of alloys containing less than 32 per cent. of copper as the quantity of copper decreases, and also in the case of those containing more than 50 per cent. of copper as the amount of copper increases.

The results, in general, confirm the existence of intermetallic compounds, and the values obtained are in accordance with those demanded by Lord Kelvin's calculation of the molecular dimensions of copper and zinc.

Royal Microscopical Society, January 16.—Annual Meeting. William Carruthers, Esq., F.R.S., President, in the chair.—Mr. Hugh M. Leake exhibited a new form of rocking microtome, designed to cut perfectly flat sections. Dr. Hebb said it seemed to remedy the defects of the ordinary Cambridge rocker, it appeared to be easily manipulated and was very stable and solid in construction.—Dr. Hebb read the report of the council for the year 1900.—The president announced that the whole of the Fellows nominated for officers and council had been duly elected, and expressed his thanks to the Fellows of the Society for again placing him in the position which he had occupied during the past year. He congratulated the Society upon the improved conditions indicated in the report. He then read the annual address, which consisted chiefly of an epitome of the life and work of John Ellis, known in his time as "Coralline Ellis."

Mineralogical Society, January 22.—Prof. A. H. Church, F.R.S., President, in the chair.—Dr. C. O. Trechmann contributed a note on an occurrence of colourless, water-clear mirabilite in gypsum-rock from Kirkby Thore in Westmoreland.—Mr. Alfred Harker discussed a question relative to extinction-angles in rock-slices. A rhombic crystal gives straight extinction in any section parallel to a bisectrix. The author has investigated the degree of departure from straight extinction introduced by a slight obliquity in the direction of section, and finds that no serious error can result unless the angle between the optic axes (measured over the bisectrix in question) is a very large one.—Prof. Lewis communicated an additional note by Mr. R. W. H. T. Hudson on the rotation of points and planes about an axis. Mr. W. Barlow exhibited a model showing an arrangement for the chemical atoms of calcite, which gives the observed crystal-symmetry and is capable of artificial twinning. He explained that the indiarubber balls forming the model are intended to show spherical spheres of influence of the atoms, and that he had arrived at the relative magnitudes which should be used by a geometrical study of elementary stereochemical properties of the carbon compounds. Such models are not supposed to throw any light on the actual forms of the chemical atoms, but are consistent with the supposition that each of these is in motion about a geometrical centre, provided that the centre retain a definite relative situation with respect to the centres belonging to other surrounding atoms. In this, like the stereochemists, he lays stress on the space arrangement of the atoms within the molecule. Mr. H. B. Hartley exhibited a device to facilitate the separation of minerals by means of heavy liquids.

PARIS.

Academy of Sciences, January 28.—M. Fouqué in the chair.—The production of hydrogen in the igneous rocks, by M. Armand Gautier. In seeking for the cause of the development of free hydrogen from granitic rocks at a red heat, it was found that hydrogen is evolved when steam is passed over red-hot ferrous salts. The reaction with ferrous sulphide was carefully studied, and found to be in accordance with the equation $3FeS + 4H_2O = Fe_3O_4 + 3H_2S + H_2$. Various rocks, after a preliminary extraction of the occluded gases by heating in a vacuum, gave, on further heating in a current of steam, a mixture of hydrogen, methane and carbon-monoxide.—The expenditure of energy necessitated by motor work and resisting work in man when raising or lowering himself on Hirn's wheel. The evaluation from the oxygen absorbed in the respiratory exchanges, by M. A. Chauveau.—The permanent secretary announced to the Academy the loss it had sustained by the death of M. J. G. Agardh, correspondant in the Section of Botany.—Diverse positions of the neutral fibre in bodies broken by flexure; the cause of fragility, by M. Ch. Frémont. In discussing the experiments of Mr. Hadfield on the mechanical properties of the iron-nickel alloys, it is shown that these results are in accordance with the views previously put forward by the author.—On the propagation of the Hertzian waves in wireless telegraphy, by M. E. Lagrange. From some experiments described, in which the wire emitting the waves was entirely underground, it is concluded that the waves do not penetrate the interior of the earth, and that there is probably absorption and reflection of the waves emitted in the ordinary way.—A study of uranium nitrate, by M. Œchsner de Coninck.—Action of boron bromide upon the iodides of phosphorus and upon the halogen compounds of arsenic and antimony, by M. Tarible. The halogen compounds of phosphorus form double compounds with one or two molecules of boron bromide. The chlorides of arsenic and antimony give an ordinary double decomposition, the bromides and iodides, on the other hand, simply going into solution without any reaction taking place.—Action of œnanthylic alcohol upon its sodium derivative; a new method of synthesis for the alcohols, by M. Marcel Guerbet. As a result of the action of œnanthylic alcohol upon its sodium derivative there is produced œnanthylic acid, di-œnanthylic alcohol, triœnanthylic alcohol, and the corresponding acid.—Direct hydrogenation in presence of reduced nickel; the preparation of hexahydrobenzene, by MM. Paul Sabatier and J. B. Senderens (see p. 354).—On the mechanism of diastatic actions, by M. Hanriot. Further experiments are brought forward in support of the hypothesis that the action of lipase is a reversible one, and it is pointed out that this reversibility is not an isolated fact, a similar action having been already indicated by Hill in the reaction of maltose and glucose. These results modify the views now held as to the function of the internal ferments in the organism.—Researches on fibrinolysis, by M. L. Camus. Immunity can be produced by injecting into the vessels substances in suspension in a 0·8 per cent. solution of salt. Injections of fibrin do not determine the production of a fibrinolytic serum, and the normal serum may dissolve the precipitate caused by the serum of an immunised animal.—On the relations of the Gregarians and the intestinal epithelium, by M. Michel Siedlecki. *Monocystis ascidiae* passes the greatest portion of its period of growth altogether in a cell of the intestinal epithelium of a Tunicate, *Ciona intestinalis*, even in its earliest stages, the Gregarian has the characters of the adult animal, simply increasing in size as its grows.—Intracellular parasitism and the asexual multiplication of the Gregarians, by MM. Maurice Caullery and Félix Mesnil. It is shown that there is a great variety of relations between these parasites and the intestinal epithelium, there being all degrees of development from a growth entirely extracellular to a completely intracellular development. — On the inversion of the heart in one of the component subjects of a living double monster, by M. Chapot-Prévost. One of the subjects, who died shortly after the separating operation, had the heart normally placed. The other, who survived the operation, was shown by radiography to have the heart inverted. This case of cardiac heterotaxy entirely confirms the ideas of Dareste on the

importance of this phenomenon in teratology.—Remarks by M. Lannelongue on the preceding paper.—On the manna of the olive, by M. Trabut. In the region of Bibans there is a considerable number of olive trees which exude during the summer a very large quantity of manna. On analysis this was found to be identical with the manna from the ash, containing about 52 per cent. of mannite.—Influence of the osmotic pressure of the medium on the form and the structure of vegetables, by M. J. Beauverie. The roots of *Phaseolus*, growing in a concentrated solution, possess no medulla, the differentiation of the ligneous tissue proceeding from the centre. There is also very early produced an abundant pericyclic cork layer, having evidently a protective function as regards the central cylinder. In a root of the same age growing in water there is, on the contrary, a voluminous medulla, and there is no premature production of cork.—On the presence of the genus *Caprina* in the Urgonian, by M. V. Paquier.—On the specific heats of silk, wool and cotton, by M. Testenoire. A reclamation of priority against M. G. Fleury.

GÖTTINGEN.

Royal Society of Sciences.—The *Nachrichten* (physico-mathematical section), part 3, for 1900, contains the following memoirs communicated to the Society :—

June 16.—O. Wallach : I. (1) On the splitting-up of cyclic oximes, (2) hexacyclic ketones, (3) heptacyclic ketones ; II. New syntheses in the terpene series.

June 30 —A. Loewy : On the transformation into itself of a non-vanishing Hermite determinant.

July 14.—E. Riecke : On the relative conductivities of metals for heat and for electricity.—D. Hilbert : Mathematical problems, an address before the International Congress of Mathematicians at Paris, 1900.—R. Fricke : Automorphous elementary forms.

July 28.—R. Fricke : Ritter's prime-form on an arbitrary Riemann surface.—A. Voss : On the principles of Hamilton and of Maupertuis.—W. Nernst and H. Reynolds : On the conductivity of solid mixtures at high temperatures.

October 27.—W. Voigt : On the inductivity of ferromagnetic crystals, with special reference to Weiss's observations on magnetite.—M. Dehn : On equivalent polyhedra (capable of dissection into congruent portions).

DIARY OF SOCIETIES.

THURSDAY, FEBRUARY 7.

ROYAL SOCIETY, at 4.30.—The Boiling Point of Liquid Hydrogen, determined by Hydrogen and Helium Gas Thermometers : Prof. Dewar, F.R.S.—On the Brightness of the Corona of January 22, 1898. Preliminary Note : Prof. H. H. Turner, F.R.S.—Preliminary Determination of the Wave-Lengths of the Hydrogen Lines derived from Photographs taken at Ovar at the Eclipse of the Sun, 1900, May 28 : F. W. Dyson.—Investigations on the Abnormal Outgrowths or Intumescences on *Hibiscus vitifolius*, Linn.: a Study in Experimental Plant Pathology : Miss E Dale.—On the Proteid Reaction of Adamkiewicz, with Contributions to the Chemistry of Glyoxylic Acid : F. G. Hopkins and S. W. Cole.—The Integration of the Equations of Propagation of Electric Waves : Prof. Love, F.R.S.

CHEMICAL SOCIETY, at 8.—Ballot for the Election of Fellows —The Action of Hydrogen Bromide on Carbohydrates : H. J. H. Fenton and Mildred Gostling.—Note on a Method of comparing the Affinity-Values of Acids : H. J. H. Fenton and H. O. Jones.—Organic Derivatives of Phosphoryl Chloride, and the Space Configuration of the Valencies of Phosphorus : R. M. Caven.—(1) Synthetical Work with Sodamide Derivatives ; (2) Note on Two Molecular Compounds of Acetamide ; (3) Diacetamide, a New Method of Preparation : Dr. A. W. Titherley.

RÖNTGEN SOCIETY, at 8.—Experiences of X-Ray Work during the Siege of Ladysmith ; Lieut. F. Bruce.

FRIDAY, FEBRUARY 8.

ROYAL INSTITUTION, at 9.—History and Progress of Aërial Locomotion : Prof. G. H. Bryan, F.R.S.

PHYSICAL SOCIETY, at 5. Annual General Meeting.—Address by the President.—Followed by a paper on Mica Echelon Grating : Prof. R. W. Wood.

ROYAL ASTRONOMICAL SOCIETY, at 3.—Annual General Meeting.

GEOLOGISTS' ASSOCIATION, at 8.—Annual General Meeting.—Twelve Years of London Geology : The President, W. Whitaker, F.R.S.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Cycle Resistance : H. E. Wimperis.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—Power-Gas and Large Gas-Engines for Central Stations : H. A. Humphrey.

ANATOMICAL SOCIETY, at 4 30.—The Origin of the Vertebrate Ear and Eighth Pair of Cranial Nerves : W. H. Gaskell, F.R.S.—A Critical Review of Recent Literature on Fossil Anthropoids : W. L. H. Duckworth.

MALACOLOGICAL SOCIETY, at 8.—Annual General Meeting.

MONDAY, FEBRUARY 11.

ROYAL INSTITUTION, at 3.—Origin of Vertebrate Animals : Dr. A. Willey.

SOCIETY OF ARTS, at 8.—The Bearings of Geometry on the Chemistry of Fermentation : W. J. Pope.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—On Her Majesty's Connection with the Society and Interest in Geography, and on Polar Exploration during the Queen's Reign The President —Progress of Exploration and the Spread and Consolidation of the Empire in America, Australasia, and Africa : Right Hon. Sir George Taubman Goldie, K.C.M.G. —Advances in Asia, and Imperial Consolidation in India : Colonel Sir Thomas H. Holdich, K C.I.E.

TUESDAY, FEBRUARY 12.

ROYAL INSTITUTION, at 3.—Practical Mechanics : Prof. J. A. Ewing, F.R.S.

SOCIETY OF ARTS, at 8.—Recent Advances in Pottery Decoration : William Burton.

INSTITUTION OF CIVIL ENGINEERS, at 8.—*Paper to be further discussed* : The Present Condition and Prospects of the Panama Canal Works : J. T. Ford.——*Paper to be read, time permitting* : The Nilgiri Mountain-Railway : W. J. Weightman.

ROYAL PHOTOGRAPHIC SOCIETY, at 8.—Annual General Meeting.

WEDNESDAY, FEBRUARY 13.

SOCIETY OF ARTS, at 8.—Arsenic in Beer and Food : William Thomson.

THURSDAY, FEBRUARY 14.

ROYAL SOCIETY, at 4.30.

MATHEMATICAL SOCIETY, at 5.30.—The Distribution of Velocity and the Equations of the Stream Lines, due to the Motion of an Ellipsoid in Fluid Frictionless and Viscous : T. Stuart —On Factorisable Twin Binomials : Lieut.-Colonel Cunningham, R.E.—Concerning the Abelian and Related Linear Groups : Prof. L. E. Dickson.—A Geometrical Theory of Differential Equations of the First and Second Orders : R. W. Hudson.—Brocardal Properties of some Associated Triangles : R. Tucker.

SOCIETY OF ARTS (Indian Section), at 4.30.—The Greek Retreat from India : Colonel Sir Thomas H. Holdich, K.C.I.E.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Capacity in Alternate Current Working : W. M. Mordey. (Adjourned Discussion.)

FRIDAY, FEBRUARY 15.

ROYAL INSTITUTION, at 9.—Electric Waves : Right Rev. Monsignor Gerald Molloy.

GEOLOGICAL SOCIETY, at 3.—Annual General Meeting.

CONTENTS.

THURSDAY, FEBRUARY 14, 1901.

DARWINISM AND LAMARCKISM, OLD AND NEW.

Four Lectures by Frederick Wollaston Hutton, F.R.S., &c. Pp. x + 171. (London: Duckworth and Co., 1899.)

THE first of the lectures printed in this volume is entitled "Darwinism," and it was delivered at the Philosophical Institute of Canterbury, New Zealand, in 1887; the second, delivered in 1898 to the same Institute, is upon "The New Darwinism"; the third, "Darwinism in Human Affairs," was given in 1882 to the students of Canterbury College, University of New Zealand; while the fourth and concluding lecture, "The New Lamarckism," has been added to render the "treatment of the subject more complete."

The author's object has been to make a clear statement of his subject, suitable for readers who are not specialists and "have no time to study more elaborate works." Throughout a large part of the work he has succeeded in this attempt, although there are passages the meaning of which is not carried on the surface. Thus, at the beginning of the Introduction, a quotation from Darwin is concluded with the words, "This, which was published in 1859, is strictly correct at the present day"; while the next sentence, opening the succeeding paragraph, reads, "In 1899 things are different." By reading on, and then turning back to the preceding page, the apparent confusion is removed, but this is hardly the way to make things easy. Similarly, on p. 9, the word "transmitted" is used in a context which seems to imply heredity, and when the conclusion has been assimilated, the next sentence informs us that the word is not used exclusively in this sense.

The author considers that the increased prominence given to isolation "is the only real advance that has been made since Darwin's death" (p. 5); but surely the question of the hereditary transmission of acquired characters is in a totally different position to-day from what it was in 1882; and the change as regards this subject from the old uncritical, somewhat slipshod attitude of the past must be counted as a very real advance. Although Lamarck receives generous treatment in the book, Buffon is altogether neglected, his suggested causes of change in the direct influence of the environment being set down to the later zoologist.

Romanes' term, "physiological selection," is criticised because, "except in the bacteria, species are not founded on physiological characters." The suggested cause of evolution is more than doubtful, but the phrase is certainly a descriptive and appropriate one to express the idea that physiological incompatibility between the germ-cells of certain individuals and those of the rest of the species may be an agency which determines the splitting of a single species into two. The suggested substitution of the phrase "progressive infertility" (p. 12) by no means expresses Romanes' idea; for he conceived of the infertility arising, ready-made and complete, as the result of spontaneous variation. When the author states that species are not founded on physiological characters he forgets (although he himself recognises it elsewhere) that the physiological characters of fertility *inter se* and of infertility with other species have been very widely looked upon as among the most important attributes of a species. Thus Huxley's criticism of the evidence for the acceptance of natural selection may be summed up in the words of his letter to Charles Kingsley:

". . . if Carrier and Tumbler *e.g.* were physiological species equivalent to Horse and Ass, their progeny ought to be sterile or semi-sterile. So far as experience has gone, on the contrary, it is perfectly fertile. . . It has been obvious to me that this is the weak point of Darwin's doctrine. He *has* shown that selective breeding is a *vera causa* for morphological species; he has not shown it a *vera causa* for physiological species." ("Life and Letters," 1900, vol. i. p. 239.)

This quotation is introduced merely to show that there is good warrant for Romanes' use of the term "physiological" in this connection, not because the present writer believes that the suggested difficulty is insuperable.

One of the reasons given for the inference "that the object of physiological evolution was the development of man" seems to be very far-fetched, viz. the existence of a number of elements

"in the world which appear to be of no use except to man: for example, gold, silver, lead, zinc, &c. . . . Not only were these made for man, but they appear to have been made as rewards for the exercise of his intellect. There are other substances, such as the rarer elements, of which no use seems ever likely to be made except the important one of stimulating enquiry" (p. 19).

A similar conviction as to the meaning of the beauty and variety of organic forms is expressed on p. 107.

In the first lecture, "Darwinism," the interesting history of the author's personal experience of evolution is recorded. He had read the "Origin" on its first appearance with avidity, and could detect no flaw in it, but thought that this must be due to his own ignorance. He was soon afterwards convinced by Sir Andrew Ramsay, with whom he went on a geological excursion to the Isle of Wight. In 1861 he wrote an article on the "Origin" in the *Geologist*, and received an extremely kind and interesting letter from Darwin (p. 34).

In criticising Darwin's statement that he owed the idea of natural selection to Malthus, a very interesting passage from the "Journal of a Naturalist" is quoted, apparently proving that the fundamental ideas about natural "checks" and "constant food supply" were clearly fixed in his mind at a very early period (pp. 40–41). The reference is not given, but the important passage should be compared in the different editions of the "Journal."

The statement that Darwin abandoned his hypothesis of pangenesis, "or thought lightly of it" (p. 51), is erroneous. The great "Life and Letters" shows clearly enough that he retained considerable confidence in it even when friends whose opinion he valued very highly did not agree with him. The chief experimental difficulties which oppose it are not alluded to (pp. 59–60), viz. the fact that mutilations, even when continued for a long series of generations, are not inherited, and that transfusion of blood and transplantation of tissue do not produce any hereditary influence.

R

The second lecture, "The New Darwinism," contains at the outset (p. 63) an entirely new and erroneous definition of the term "Neo-Darwinian." "The Neo-Darwinians, as we are sometimes called, accept Darwin's teaching, and supplement the theory of natural selection with *methods of isolation*" (italics the author's). As is well known, the term was really applied to those who accepted only that part of Darwin's teachings which was originated by him, and excluded that small but distinct element of Lamarckian doctrine which he incorporated with his own. The history of the use of this term and "Neo-Lamarckian" is as follows. A school of Lamarckian evolutionists grew up in the United States, and reached its maximum about the time that the question of the hereditary transmission of acquired characters became acute, viz., 1887 and the following years. It consisted of Cope, Hyatt, Ryder and several other naturalists; W. B. Scott and H. F. Osborn belonged to it in those days. The members of the school chiefly looked at evolution from the point of view of palæontology. They called themselves Neo-Lamarckians, because they rejected Lamarck's more extravagant suggestions, but believed that in the remainder they had found a satisfactory basis for evolution. When, owing to Weismann's writings, the scope of heredity began to be rigidly investigated, many naturalists quickly recognised that grave doubt was thrown upon the whole of Buffon's and Lamarck's suggestions as to the causes of evolution, and they took their stand on natural selection alone among all hypotheses as yet proposed. In this they followed Weismann and Wallace, and they were called by those who did not agree with them "Weismannians" or "Neo-Darwinians," the term "Darwinian" being reserved for those who believed the whole of Darwin's teaching—the extrinsic element as well as that peculiar to him. This at any rate, was the attempted achievement of the labellers. The naturalists in question had never selected the label which it was sought to affix to them, nor were they pleased with it, as were the Neo-Lamarckians with their invention. They, or at any rate many of them, protested against the term "Darwinism" being used necessarily to include an element extraneous to Darwin, although accepted by him, of very doubtful validity, and liable, if entirely abandoned, to drag down with it the historic title derived from the name of the great English naturalist. "Darwinism," applied, as Wallace applies it, to the hypothesis which was originated by Darwin, is liable to no such objection, and these naturalists maintained that it is in every way appropriate to thus describe natural selection, the one and only suggested cause of evolution which seemed to them to possess any significance or value. The history of the whole controversy is to be found in letters and articles printed in this journal for several years following 1887.

In this second lecture many examples are given of what are believed to be useless specific characters (p. 69–73). The exigencies of space prevent any detailed criticism, but it may be generally stated that many of the cases cited are extremely unconvincing. The question of incipient variations is briefly alluded to without any reference to Dohrn's principle of "change of function," which offers so probable an explanation of many difficulties.

One of the best features of the book is the use made of the natural history of New Zealand and the southern seas (as on pp. 87, 90, 91, &c.).

In the third lecture, "Darwinism in Human Affairs," there is a clear statement of the way in which selection acts on a group of competing individuals distinguished by variation (pp. 110, 111). The concluding sentence of the lecture, on p. 133, is distinctly out of place in a work of this kind. Those who have written on the relations of religious thought and doctrine to the teachings of science have always been welcomed by a large body of readers. But it is unwise, and, fortunately, rare, for the two sets of ideas to be jumbled together haphazard, so that in a professedly scientific work we are suddenly brought up with a shock by some short sentence expressing a religious conviction. The object which the author probably has in view is not advanced by such a method.

The concluding lecture, on "The New Lamarckism," contains much cautious and interesting reasoning upon various instances which are believed to prove the existence of the Lamarckian factors of evolution; although the part which the nervous system probably plays in many of the changes, such as those of pupæ (p. 141) and of mammalian hair (p. 142), is neglected. The opinion that retrogression follows as a natural result of the cessation of selection is rejected by the author (p. 157), as we might expect, seeing that he does not allude to the conception of a condition of unprogressive equilibrium still requiring the unremitting aid of selection for its support. In this lecture, too, there is a further dogmatic statement as to the uselessness of certain structures or features. Among these the white under-side of flat fishes is instanced as probably due to disuse-inheritance (p. 160); but Abbott H. Thayer's interpretation of white under-sides generally may very probably be applied (as, indeed, Mr. Thayer believes) during the movements of these fish. The statement that "the thickness of the legs of the moas was of no advantage to them. On the contrary, it was distinctly a disadvantage" (p. 160), is an example of dogmatism concerning conditions of life of which we are extremely ignorant.

The author is inclined to believe in certain examples of "disuse-inheritance," although he generally criticises the evidence for "use-inheritance." He forgets that passive structures which are useful, but not physiologically altered by their own utility, degenerate when they cease to be useful, no less than the active structures which are modified by their own use. This argument, *mutatis mutandis*, affects equally the supposed use-inheritance.

In the case of certain New Zealand alpine plants, it is contended that there is good evidence for the transmission of an acquired character. *Olearia nummularifolia*, var. *cymbifolia*, produces leaves characteristic of the local alpine plants, but "the leaves on new shoots revert to the ordinary form if the plant is removed to the low land; thus showing that the peculiar shaped leaf is an acquired character and not inherited." On the other hand, the alpine *Veronica lycopodioides*, having a leaf similar to that of the *Olearia*, does not change when grown at a low level, "and we must, therefore, assume that an acquired character has here become congenital" (p. 165). The probable explanation is that natural selection has rendered the former species susceptible to

the influences of two very different sets of conditions, while the latter has been led by it to a single fixed form suitable to a single set of conditions. This is only a suggestion, and might require modification after a special study of the circumstances of the two species; but it is sufficient to show that we require far more evidence before it can be conceded that such transmission had been made in any way probable.

The book is well and clearly printed. A portrait of Lamarck forms the frontispiece. E. B. P.

THE RATIONAL TEACHING OF MATHEMATICS.

The Teaching of Elementary Mathematics. By David Eugene Smith, Principal of the State Normal School at Brockport, New York. Teachers' Professional Library. P. xv + 312. (New York: The Macmillan Company. London: Macmillan and Co., Ltd., 1900.)

IN many training colleges for primary school teachers there are elaborate courses of study on psychology and ethics. Surely a knowledge of morals and of the mental machinery of boys and girls would be more certainly and more easily acquired incidentally during other studies, such as the natural sciences; but at these colleges there is seldom any attempt to educate through the natural sciences. We have, though not to the same degree, the same feeling about courses of instruction in mathematics. There is a cold-blooded formality about the mere name which tells all children truly that they are being offered stones for educational bread. But if there must, unfortunately, be separate courses of instruction in mathematics, we should, if we were children, dearly love to be taught by Mr. Smith. He is well read in his subject, and teachers who are also well read will take pleasure in seeing the best views so clearly put forward; teachers who are not learned in the subject will benefit greatly by reading this book. Short sketches of the histories of arithmetic, algebra and geometry are woven into the text in such a pleasant fashion that one reads and understands without much effort. The merits and demerits of various systems of teaching mathematics to very young children are clearly stated, but we cannot help thinking that too much is made of the philosophy of the numerous German exponents of pedagogy. There is no system which will give good results in the hands of a fool; there are many systems which will work fairly well in the hands of the average teacher; a thoughtful man who is in sympathy with his pupils will succeed with any method that he is likely to adopt.

Philosophers are too fond of distinguishing between teaching for *utility* and teaching for *culture.* We take it that even if we teach mathematics for its "bread-and-butter-value," if we teach so that a pupil really understands what he does, then we are really training his logical powers and giving him help in his ethical, religious and philosophical ways of thinking. The more we try to teach merely for culture the more do we make the reasoning obscure and difficult. As if a good teacher could possibly give sordid notions to his pupils! What we really want is that all teachers shall know their business, and then, however quickly they may make their children cover the ground of elementary mathematics, and we say the quicker the better, the children will be taught as rational beings. Much of the arithmetic taught in schools is really the teaching of a trade. A particular rule like *Practice* is merely the application of arithmetic to the trade of a grocer. So also rules like *Interest* or *Discount* are labour-saving rules, useful when one has thousands of calculations of the same kind to make, easily learnable by a boy after he leaves school if he has a knowledge of simple arithmetic and if his common sense has had a fair chance of development. Children may be kept for years at "rules" of arithmetic which they never understand, by an unscientific teacher, and this is what the philosophers condemn as utilitarian teaching. There is as little *utility* about such teaching as there is *culture* in that of the equally unscientific follower of the greatest psychologist. Of the two, however, the unscientific utilitarian does least harm, for he makes least pretence; he only stupefies the brain, the other destroys the soul.

Indeed, the man who aims exclusively at culture always hurts the soul of his pupil, for he teaches that what is useful must be low, and that the study of it must lead to sordid thought. We can no longer afford to laugh when men assure us that they scorn the results of their studies when these results prove to have useful applications. So long as these men were few in number they might be laughed with; we laughed because they were paradoxical and because we did not fear that the utility of a study could really be lost sight of. We are always grateful to philosophers who discover new truths, whatever their notions as to their utility may be. But when the stupid admirers of these men erect their paradoxes into articles of belief; when headmasters with much capital invested in teaching machinery find that such articles of belief give a fictitious value to their invested capital; when as a result, 98 per cent. of the boys leaving school at seventeen to nineteen years of age know no mathematics, although they are supposed to have been studying mathematics for many years; when we have overwhelming proof from the fields of war and commerce and manufacture that the best race of men in the world is held by want of education, as if by enchantment, from exercising its natural powers—then we feel that the time has come when a crusade ought to be preached against the pestilent heresy.

We are very glad to think that Mr. Smith gives great weight to the opinions of Profs. Henrici and Minchin about mensuration and geometrical teaching. Lacroix expressed them clearly, so did Clairaut and Voltaire and Hoüel and Spencer and Langley, and many another educationist. Laisant says, "But just as there must be a preliminary preparation for arithmetic—namely, practical calculation—so theoretical geometry should be preceded by the practice of drawing." Rousseau said that for young pupils "geometry is merely the art of handling the rule and compasses." Mr. Smith describes the use of shears and cardboard, and he suggests how to follow Galileo's experimental and inductive methods in mensuration, even with boys of intermediate grades. As for demonstrative geometry, Mr. Smith says that in America it usually begins in the tenth or eleventh school year.

"To begin a work of the difficulty of Euclid any earlier than this will hardly be sanctioned by American teachers; the hard Euclidean method must change, or the subject must remain thus late in the curriculum. If the object were, as seems to be the case in England, to cram the memory for an examination, it could be attained here as easily as there. But the considerable personal experience of the writer, as well as the far more extended researches of others, convinces him that as a valuable training in logic, as a stimulus to mathematical study, and as a foundation for future research, the study of Euclid as undertaken in England is not a success."

He then quotes Prof. Minchin, who says:—

"Why then is it that the teacher, when he comes to the teaching of Euclid, is confronted with such great difficulties that his belief in the rationality of human beings almost disappears with the last vestiges of that good temper which he himself once possessed? The reason is simply that Euclid's book is not suitable to the understanding of young boys."

We wish that Prof. Minchin had gone further and said that whereas every boy and man takes an interest in experimental science, including geometry and mensuration, only a few ever take an interest in demonstrative geometry; and it is both wrong and foolish to insist on its being learnt by boys whom it stupefies, whatever their age may be. All educationists are agreed that the English system of insisting on all young boys learning demonstrative geometry is quite wrong. Certainly, we know of no educationist who has a word to say in favour of the system prevailing in all English schools. We take it that the system is maintained because it does not "pay" the pupil in any sense whatever. Prof. Hudson is quoted as saying, "To pursue an intellectual study because it 'pays' indicates a sordid spirit." Working at geometry indicates no sordid spirit in our boys, but we are not so sure as to what it indicates in the masters of English schools. It "pays" them very well indeed.

Give the brains of an average English boy a chance of development, and he is full of common sense and self-reliance and scientific method; and yet the average boy leaves our schools uneducated, with no knowledge, and with the belief that he is stupid. Even Pythagoras did not think that more than a very few men were capable of the study of geometry; hardly one legislator or ruler or warrior from the time of Pythagoras to that of Pappus made a study of geometry, although this was a time when there were few kinds of intellectual study.

Mr. Smith's statements as to the history of the subject are fairly acceptable, as he keeps clear of debatable matter.[1] Throughout, he is unwilling to give Semites much credit, and I presume that it is in consequence of this that, in describing the work of Diophantus, the Alexandrian beginner in what we now call algebra, he forgets to mention that in all probability all the early life of Diophantus was spent among Asiatic peoples. Algebra, as we know it, dates from the time of Haroun of the "Arabian Nights." No doubt it comes altogether from the Semites of thousands of years before—the Semites who gave us all religions and the usages of older civilisations, without being able to give us their own subtler instincts; who taught Homer the decoration of a shield and Pericles how to beautify Athens; who gave Greece all its geometry through Pythagoras the Tyrian; who allowed Thales and Herodotus and other peripatetic students to absorb their science; who taught the doctrine of humanity to Socrates, and who did not mind taking to themselves Aryan names either in Troy or Alexandria or London.

The earnest reader of Mr. Smith's book will probably be led by it to think things out for himself. It is not important that he should subscribe to the author's opinions. Indeed, these opinions are rather in opposition to one another, for Mr. Smith is able to see that there is much to be said in favour of the views of almost all the writers whom he quotes. He gives many hints which will be found very suggestive by a thoughtful teacher of arithmetic and algebra who is not himself a good mathematician. They may, however, lead a common man to obscure the minds of his pupils, giving them, for example, all the historical methods of solving quadratics before they know much about quadratics. When one clears an equation of fractions by multiplying all across by some function of the unknown, the resulting equation contains other roots than the original one—yes, but it is not wise to trouble beginners with too much of this. One may philosophise deeply over our very simplest notions, but "Sartor Resartus" ought only to be read by grown-up people.

JOHN PERRY.

[1] As this notice was getting too long, we have cut out much of what we had written. We have here cut out some remarks as to the claim of Napier of Merchiston to the invention of the use of decimals. But it is rather important to re-write an observation made long ago by Prof. Ayrton:—"The units ought to be symmetrical with regard to tens and tenths, and it would be more scientific to write 1500·0032 as $15\bar{0}0032$ or $15\dot{0}0032$, or in some other way which shows its symmetry. It is astonishing what trouble is given by the difference in rules between finding the logarithm of a number like 500 and a number like 0·05. If they were written $50\dot{0}$ and $.\dot{0}05$ we should have the same rule for both. If we must retain the present unscientific method, let writers who wish to avoid printers' errors avoid ·05 and always write 0·05."

HUMAN ORIGINS.

In the Beginning (*Les Origines*). By J. Guibert, S.S. Translated from the French by G. S. Whitmarsh. Pp. xvi + 379. (London: Kegan Paul, Trench, Trübner and Co., Ltd., 1900.)

THE author of this book is the Superior of the Institute Catholique in Paris, but when he wrote it he was professor of natural science at Issy. The book is the outcome of an endeavour to train young ecclesiastics who, in the future, would have to propagate and defend the faith. It is rightly insisted as most essential that young clerics should be wanting in no knowledge concerning humanity; and it is pointed out that two perils of equal danger have to be avoided—an ill-founded compliance with the theories in favour amongst the learned, and a blind attachment to certain ideas which have no firm foundations, but which some men erroneously consider as identical with the faith. The author imposes on himself the three following obligations: (1) honestly to explain systems, (2) assert with firmness what is well established, (3) leave the questions open which have not yet received a solution; and he concludes his preface thus:

"If, as science advances, it should illuminate some doubtful point, or show the fallacy of some solution which I had looked upon as finally settled, I should not hesitate to yield myself to these indications. And if the Church, in whose infallibility I firmly believe, should deliver a judgment contrary to my assertions, I am ready, in advance, to accept her teaching."

It is interesting to note how this very earnest and conscientious teacher treats his subject, as he evidently endeavours to present the main results of scientific research to his readers so that they may be prepared for the shock of a possible future meeting with scientific doctrines which might imperil their faith.

The "Church" has, very wisely, not pronounced definitely on many scientific problems, and concerning these it is open to an intelligent Roman Catholic to hold fairly advanced views; for example, the cosmogony of the Bible is one of these, and the reader is permitted to take his choice of the three main interpretations of this account. The most, too, is made of our ignorance concerning the origin of life and the actual precursors of man. The author regards himself as an evolutionist, but he is not a thoroughgoing one, as he distinctly affirms that the theory of evolution can neither be applied to the origin of life nor to man. He asserts that

"evolution, even had it realised the progression which unites all animals in one nature, could not have produced that new creation which is known as an intelligent and free man."

The author admits that the volume has no scientific pretensions, and he goes on to say "were it judged with the utmost rigour it would not disturb me." All the same, the book would have been less open to criticism if it had been looked over by specialists, as there are many statements of theories or facts that, to say the least, it would have been much better to have put differently, and there are many errors of nomenclature and misprints that should have been avoided. For example, Noctiluca is called a "jelly fish" (p. 75), *Aurelia oecrita* (*sic*) is termed a Madusa (p. 82). As examples of errors of fact may be instanced, the Australians are credited with a "wide head" (p. 368); the Bushmen are degenerate Hottentots, and these, according to "eminent ethnologists," are "emigrant Egyptians, debased and deformed by misery" (p. 372).

We have given this book as much space as it deserves as a popular exposition of human origins; but nevertheless it is probable that it will be of service, as it should make some religious people think on subjects that they too often ignore, and, at all events, it will indicate to "good Catholics" that certain of their own religious teachers do not entirely repudiate modern science or entirely reject the theory of evolution.

OUR BOOK SHELF.

Atti della Fondazione scientifica Cagnola. Vol. xvii. Pp. xxvi + 355. (Milan: Tip Bernardoni di C. Rebeschini, e c., 1900.)

UNDER the Cagnola foundation, two prizes are annually awarded for essays on subjects proposed by the founder, and one prize of about 100*l*., with a gold medal of the value of 20*l*., are awarded on a subject chosen by the Reale Istituto Lombardo. The theme for 1898 was a critical exposition of the theory of electrical dissociation, and the successful memoir by Profs. Angelo Battelli and Annibale Stefanini forms the subject of the present volume.

Among the various theories of solution, that of van 't Hoff, which regards the dissolved substance in a dilute solution as existing in the gaseous state, has found much favour; but determinations of molecular weight derived by this hypothesis do not agree, especially in the case of electrolytes, with those obtained by other methods or deduced from the chemical formulæ. This circumstance, coupled with the fact that the least electromotive force suffices to generate a current in an electrolyte, had already led Clausius to replace the hypothesis of Grotthus by other theories; and Arrhenius, observing that the anomalies in the osmotic pressure and the freezing-points occur exclusively in solutions of electrolytes, was led to the hypothesis that these contain the acids and salts in a state of dissociation, increasing with the dilution.

This hypothesis of electrolytic dissociation has been put by the authors to a variety of tests in connection with the mechanical phenomena of osmotic pressure, optic phenomena, thermal phenomena connected with freezing- and boiling-point determinations, and, lastly, electric phenomena; and while many of the results favour the hypothesis of the existence of free ions in solutions, others are difficult to reconcile with this theory. Thus the degree of dissociation required to account for optic phenomena does not always agree with that deduced from cryoscopic or ebullioscopic observations, or from electric conductivity. Moreover, the authors do not consider it conclusively proved that there is no inferior limit to the electromotive force sufficient to set up a current in an electrolyte.

It will be thus seen that Profs. Battelli and Stefanini have opened up a wide field of discussion in connection with electrolytic theories, and that their work, both theoretical and experimental, will be of no small assistance to chemists and physicists interested in researches in this subject.

An Elementary Treatise on Qualitative Chemical Analysis. By Prof. T. F. Sellers, A.M. Pp. 160. (Boston: Ginn and Co., 1900.)

THE author justifies his contribution to the long list of analytical works by pointing to the inevitable gap. The gap no doubt exists. The question is whether it is desirable to fill it. We have analytical books which mean business, and, being written for analysts and not for students, are crowded with practical details. Then there are the countless examination cram books, which by tabular and other devices direct the student by the shortest cuts to his ultimate goal—the discovery of the constituents of salts, simple and complex. The present little volume is to fill the gap which lies between these two extremes, and its advantages are set forth in the preface under six principal heads and eight subsidiary ones. Without transcribing literally these manifold recommendations, it may suffice to say that the book opens with the principles of analytical chemistry by introducing the theory of solution, osmotic pressure and electrolytic dissociation, and proceeds with the usual series of qualitative tests for bases and acids and their methods of separation.

However desirable it may be for even an elementary student to gain some knowledge of analytical chemistry based upon the modern theory of solution, a beginner should first be confronted with his experimental facts. A reversal of the present order might therefore be adopted with advantage. An advantage, too, would be derived from the introduction of a few illustrations, descriptive of the apparatus mentioned in the text.

As to whether a student, such as the author contemplates, who does not intend to specialise in chemistry, gains very much from the detailed study of analytical operations, is open to question.

The study of qualitative analysis as a substantial part of elementary practical chemistry has been determined largely by tradition, partly, too, by the exigencies of examination, to which it readily lends itself; but it is worth consideration whether the emphasis laid upon it

on these grounds is not exaggerated, and whether a student who studies chemistry for one year could not fill his time with practical problems of greater value.

J. B. C.

Microbes et Distillerie. Par Lucien Lévy. Pp. vi + 323. Paris: Carré et Naud, 1900.)

THIS book, which deals with the micro-organisms connected with distilling operations, supplies a good illustration of the rapid progress that is being made in the study of technical mycology. M. Lévy confines himself strictly to his subject, and does not wander into the details of practice, and yet the three hundred and twenty odd pages of his book are none too many for a very brief *résumé* of much that is known concerning the relations of micro-organisms to the distilling industry. But brief and condensed though it is, it is accurate and very fairly complete, and, moreover, possesses that charm of simple rendering which is so characteristic of the best class of French scientific literature.

The book will be useful to all interested in the technology of the fermentation industries; but we are inclined to go farther, and also recommend it to the notice of students of pathogenic micro-organisms. There appears to be some little danger of too wide a separation of this branch of bacteriology from the science as a whole, and any such artificial division can only work for harm. Probably much of the knowledge gained concerning the micro-organisms of fermentation and their actions has some bearing on pathological bacteriology, and for this reason we recommend M. Lévy's book to pathological bacteriologists as a concise and suggestive *résumé* of another branch of their science. Doubtless it reflects more especially the work and views of the French school, but then it is published in the land of Pasteur.

A. J. B.

The Fifth Report upon the Fauna of Liverpool Bay and the Neighbouring Seas. Edited by Prof. W. A. Herdman, F.R.S. Pp. ix + 336. Twelve plates. (Liverpool Marine Biology Committee, 1900.)

THE reports and other publications of the Liverpool school of naturalists have provided material for many paragraphs in our "Notes" columns, the latest "Memoir" published by the Liverpool Marine Biology Committee having been noticed quite recently (p. 330). The present volume contains reprints of the annual reports of the Committee, from the ninth to the thirteenth inclusive, papers communicated to the Biological Society of Liverpool on Copepoda, Hydromedusæ, Turbellaria, Actinia, and an abnormal Echinus, and a list of the marine fauna and flora of the Irish Sea. The record of the L.M.B.C. is brought down to the end of its sixteenth year, and observations extending over several years, referring to the marine biology of Liverpool Bay and the Irish Sea, are rendered available in a convenient form. The volume stands as substantial evidence of what valuable work a few good naturalists can do, even when the financial resources are limited.

Analytical Tables for Complex Inorganic Mixtures. Arranged by F. E. Thompson, A.R.C.S. Pp. 7. (Stafford: *Chronicle* Office.) Post free, 1*s.* 7*d.*

A SERIES of tables suitable for use in chemical laboratories where students are working at qualitative chemistry, with an examination like that of the advanced stage of practical inorganic chemistry of the Board of Education in view. The tables show how to conduct a preliminary examination of a substance in the dry way, and in the wet way for metals; and they describe the usual treatment of group precipitates and filtrates. There are also tables for examination for acids and giving confirmatory tests for acids.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Mathematics and Physics in Public Schools.

A WELL-ATTENDED conference of science masters in public schools was held last month at the University of London, and among the many interesting papers read was one by Mr. W. D. Eggar, of Eton, on the coordination of mathematics and physics in our public schools.

In answer to that paper I endeavoured to point out at the time that the present want of cohesion between these studies was due, not to the incapacity of the instructors in these subjects, but to the illiberality of the system still prevailing, not only in the Universities to which many of the boys eventually go, but also to an equal degree in these public schools themselves.

I will here take the opportunity of thanking the editor of NATURE for his courtesy in inviting me to express my views at greater length. This letter is a plea for a change in the order of teaching mathematics in the older public schools, and contains a suggestion as to how such a change could be effected.

The points I wish to call attention to in this letter are that (1) the hands of mathematical teachers in these schools are tied by the conditions of the University examinations; (2) in arithmetic more attention should be paid to the decimal system; (3) the Euclid should be curtailed and some of it put into algebraical form; (4) too much time is given to artificial questions in algebra; (5) trigonometry ought to be begun earlier; (6) more hours might be allotted in the week to mathematics and physics; and (7) the classics are given an abnormal and unjustifiable preponderance in an ordinary boy's education.

I am quite aware that the difficulties to be overcome in effecting any rational common-sense change in the methods and order of teaching elementary mathematics will be very great, but let us hope they will not prove insurmountable.

To begin with, the public schools for boys of average ability are bound to more or less base their scheme of work on the pass requirements of the Universities, though perhaps at Eton this may be less the case than at many other schools. After those requirements have been satisfied the teaching does not by any means always shape itself in the direction of the work a boy may afterwards follow while at the University or in after life. As things are, what is the present condition of the average boy at our older public schools?

In arithmetic he gains a certain amount of proficiency in those fractions known as vulgar, he learns the artificial rules for extracting square and cube roots, he works out problems involving questions of time and work, or of time and distance, or of areas, he becomes quite proficient in the ordinary matters of compound interest, discount, stocks and shares, and he even gains an idea of what a stockbroker is. I am not prepared to say that all this has not its educational, and even its commercial, value later on, for it certainly has; but what I maintain is that we do not go far enough. There is not enough chance, our pass examinations being what they are, of boys seeing the value and importance of the decimal system as applied to physical measurements and problems. They are often apt to imagine that a result must be absolutely correct to its last decimal place, or it is valueless; and the methods of approximation are often excluded from their course altogether, either as being not sufficiently accurate or not required for the University entrance or pass examinations.

Let us turn now to the question of Euclid. Geometry is an excellent form of mental gymnastics when it is taught in the proper way, but the manner in which it is presented to the boy in our editions of the great geometer is antiquated and out of date. Far too much in this abstract science is left to the imagination, a quality which the ordinary boy frequently lacks; and ocular demonstration is but little resorted to in order to give him, by means of figures and models cut out of cardboard, a clearer idea of what he is required to prove. I also venture to think that the Euclid, such as we know it, is spun out to an excessive length, and too often the patience and courage of the average boy is well-nigh spent before he gets to the end of it.

I am fully aware of the existence of that useful body known as the Association for the Improvement of Geometrical Teaching, or, as it is now called, the Mathematical Association, of

which I have the honour to be a member, but it is a large problem which it has to face, and it is to be hoped that its publication will not fall too much into the way of merely publishing solutions of interesting and sometimes recondite conundrums.

I should like to see a more rational form of geometrical text-book in common use, in which many of the propositions of the second and fifth books are merely translated into algebraical language, and ratios and symbols more widely employed in the sixth book to shorten many of the propositions.

Again, no doubt, trigonometry is postponed till too late a date, and in many cases it is not begun at school at all. Why should not every one gain a reasonable notion of the sines, cosines and tangents of angles at a much earlier stage in order to supplement his knowledge of geometry? I would not recommend a beginner to employ himself for hours, as is often the case, in proving long, and to him cumbrous, identities, but leave such work to the professed mathematician. It would be more profitable for the boy to plot out graphs of the simpler functions on squared paper and thereby gain an early notion of coordinates. He should also be taught much earlier a practical working of logarithms, and not postpone it until perhaps he has got beyond the binomial and experimental theorems.

What do we find, too, in the teaching of elementary algebra? There seem to be the same unpractical methods at work here. Boys spend considerable time over the ordinary rules in the early part of their text-books, and often no suggestion is made to them that algebra is but a convenient method of expressing general ideas in a shorthand form. The fundamental notions of ratio, proportion or variation are kept from them because, if you please, the chapters on them are printed somewhat late in their text-books! Too frequently the average question merely involves a bristling array of letters and brackets which have to be simply eliminated or removed. Seldom is an appeal made to a boy's faculties of sight and touch, and seldom is any apparatus for measurement placed in his way. The present order of things may not do much harm to the boy of mathematical ability, if he means to make a special study of the subject; but for the rank and file it is wrong, if they are to coordinate their mathematics with a good working knowledge of the calculus of experimental science.

Here I must make mention of a very valuable article by Prof. Perry in NATURE of August 2, 1900, and I only regret that, as I was away at the time, I was not aware earlier of its existence. I need only say that I am heartily in accord with him in advocating some such scheme as he there proposes. To turn now to what I hope may prove a practical suggestion. It would not be possible to change abruptly from the present arrangement to such a scheme; but the process could certainly be gradual, and a larger, gradually increasing, proportion of hours for experimental work might well be introduced into the curriculum. Surely the University of Cambridge might lead the way and bring into its previous examination some form of physical science, theoretical and practical, in order that all young men may obtain some idea of the practical applications of mathematics. Why is it that so many young men at Cambridge find the subject of physics so difficult, and are sometimes induced to abandon it for some other form of science? My answer is that their previous mathematical education has often been conducted on the wrong lines, and their knowledge is not of that kind which is required of them in the laboratories.

The University of Oxford is, however, a far worse offender in its mathematical papers for responsions and matriculation. The arithmetical papers set are thoroughly on the orthodox lines, and this is very well as far as it goes; but there is no hint of any application of arithmetic to practical work. The rest of the mathematics required is truly ridiculous; a candidate may either take an elementary algebra paper, carrying him about half-way through the subject, or a paper on the first two books of Euclid, and the latter alternative is strongly recommended by the authorities. Note that he must not take *both* subjects, so that the candidate is given to understand that these two subjects are divided off into separate compartments, and may have no more relation to one another than biology has to Greek iambics. Moreover, from what I understood in a speech at the Conference of Science Masters, a young man who would offer physics for a scholarship does not always meet with the encouragement he deserves from the authorities at certain colleges, and *a fortiori* no pass candidate is expected to even trouble himself about the subject.

With these difficulties in our way it cannot be expected that very much towards realising Prof. Perry's ideal has yet been achieved; but, in addition to what I have said, there is no doubt that the number of hours given to the study of mathematics or physics at our older public schools is woefully inadequate. It is useless to say that so much money is spent on these subjects. Unless more time is given to them for each individual boy, satisfactory results cannot be produced, much less can an advance be made towards coordinating the two subjects.

A great debt of gratitude is due to men like the late Prof. Huxley in furthering the cause of science in the public schools, but we do not want to stay where we are. An answer to the practical question of how we are to fit more time into the working day involves the removal of compulsory Greek and an alteration of the classical scheme. Education is very much in the air just now, and when Lord Rosebery, Sir John Williams and others, in the last few months, speak publicly upon this subject, it is greatly to be hoped that reforms will be brought about.

The old theory is, that it does not much matter what a boy is taught at school provided he is made to work. This, to my mind, is a most mischievous doctrine. The average boy has only a limited capacity and a limited time for learning to fit himself for his life's work, and it must be discouraging to him to find, when he leaves school, that he knows absolutely nothing about the work by which he may be going to earn his bread. Not every boy is capable of becoming a classical scholar with a fine critical instinct; let those who are by all means be encouraged in every possible way. But it is for the average boy that I plead, and I ask why so much of the old studies should be thrust down his throat when modern life will require of him a knowledge of a great deal besides.

I do not desire to enter into a long discussion of the merits of a classical education, but in the older public schools some change must be brought about if we are to devote more time to modern subjects, and it is for this reason that I have introduced the question here. A spirit of quasi-mediævalism still seems to be numbing the existence and warping the educational growth of these schools. Far better would it be if a change came about from within; but will anything short of another Royal Commission bring about the necessary reforms?

Athletics fill a large part of school life, and it is natural that they should appear important on a healthy boy's horizon. It is, therefore, all the more necessary he should be properly guided in his work before the time comes when he can judge for himself. Perhaps too much time may be given to sports; be that as it may, a boy in each day cannot work more than a certain number of hours, but while he is at work, for heaven's sake let us teach him more of the things which are likely to stand by him afterwards. I have too much respect for the older public schools to wish to see them left behind in the race by vigorous younger sisters; but we, who are concerned with such schools, cannot shut our ears to the peremptory demands for a more rational education, if our national life and character are to play the same part in the future that they have done in the past.

G. H. J. HURST.

Eton College, Windsor, February 12.

The Use of Mosquito Curtains as Protection against Malaria.

IN your issue of December 20, 1900, is described the use of mosquito curtains against malaria in Egypt. It is, I suppose, generally known that in India they have been used for many years in a similar fashion. Between 1872 and 1883 I travelled and camped in some of the most malarious jungles in India. Sometimes I had to travel, like a Boer, in light marching order; but mosquito curtains, I can well remember, were the last things to be left behind. Their efficacy in those days was attributed to a filtering action; and, following out this idea, I used (especially in very feverish districts) to employ curtains composed of thin porous sheeting. I can still recollect the various stories of the efficacy of mosquito curtains against malaria.

There seems to be an opinion amongst men who go north into the malarial districts of Rhodesia, &c., that Dr. Ross's splendid discovery does not cover quite the whole ground. One can recollect how, in certain countries, certain winds (apart from mosquitoes) inevitably bring attacks of fever, even in those who are apparently free at the time from infection. On the Nilgiris, in Southern India, between 6000 and 7000 feet high,

malarial fever is unknown on the spot, but a man may turn over the ground in certain marshy localities and get fever certainly whenever he does so. It was common experience in India that the drinking of certain water, such as that from the highly malarious Western Ghaut forests, would inevitably cause malarial fever.

In many malarious localities, especially parts of China, it is sufficient to turn the ground over to apparently poison the atmosphere and induce malaria in those who are near. There is a medically authenticated case of fever being contracted from newly turned-up earth carried in baskets by coolies past a window. When this and other cases come to be re-examined they may be found traceable to mosquito-born Hæmamœbidæ; but it is difficult to account for them all in this way, and, as I mentioned, there seems to be an opinion amongst Northern men here that all cases of malarial fever cannot be attributed to Anopheles infection. D. E. HUTCHINS.

Conservator of Forests, Cape Town, January 19.

Audibility of the Sound of Firing on February 1.

I ENCLOSE a record of the sound of the guns heard at Eastbourne, commencing at 3h. 14m. and ending at 3h. 57m. As you will see, the sounds came with great regularity every minute, but the period which the sound covered in each minute gradually fell off from eleven to about five seconds. My observations were checked by a friend, and we were stationed on the summit of a down some 500 feet above sea level with a clear sea horizon out to Newhaven. The distance to the Solent is about sixty-five miles, and there was a slight wind from the North-West. I should like to try to describe the sounds which, though faint, were perfectly distinct—er-er-er-pup-er-er-pup-pup, the detonation sound being more marked towards the end of each period. I need not say that the sounds were indescribably mournful to listen to. H. D. G.

Audibility of the Sound of Firing on February 1st.

Sound commenced at h. m. s.	Sound ended at h. m. s.	Duration of sound s.
3 14 7	3 14 18	11
3 15 8	3 15 19	11

3 54 11	3 54 14	3
Reports continued until 3 57—but impossible to time—so very faint.		

Sensational Newspaper Reports as to Physiological Action of Common Salt.

IN the interest of the dignity of scientific research I venture to hope you will print the following statement. Some American papers have recently published sensational and absurd reports of physiological theories and experiments whose authorship they attributed to me. These reports, which in America nobody takes seriously, were reprinted and discussed in European papers. I hardly need to state that I am in no way responsible for the journalistic idiosyncrasies of newspaper reporters and that for the publication of my experiments or views I choose scientific journals and not the daily Press. JACQUES LOEB.

The University of Chicago, Physiological Laboratory, January 16.

The Publication of Books without Dates.

Is it not time that men of science should raise a protest against the publication of books without a date on their title-page? This is a practice which has been common to maps and a certain class of books of reference, and it comes, to my mind, very near to being a deliberate fraud, as it seeks to pass off as new that which is more or less obsolete. We should surely do our utmost to prevent this habit from spreading to scientific books, such as the translation of van 't Hoff's "Physical Chemistry," which is reviewed in NATURE of February 7. O. HENRICI.

Central Institution, Exhibition Road, February 9.

Optical Illusion.

IT seems to me certain that the phenomenon illustrated in NATURE of February 7 (p. 353) is due to (1) *fatigue*, the cause of the reversed image seen when one looks away from the diagram on to white paper, combined with (2) *involuntary and incessant slight movements of the eye.*

Of course the reversed image, white squares and black lines, when one looks away on to white paper, is well known. With me it does not appear to occur at once, but after an interval; and it is intermittent, fading and recurring several times.

Now, when one gazes at the diagram, the eye moves incessantly to a slight extent; and so it is only the central part of the images of the white spaces that fall always on parts of the retina continually fatigued; the edges, near the black squares, fall on parts of the retina that have, on the whole, a good deal of rest owing to the fact that they are occupied for half the time (or so) by the images of the black squares. I do, in fact, see dark lines along the central portions of the white spaces, and the dark patches spoken of are where these dark lines cross.

I can make the horizontal dark lines disappear by purposely giving my eyes a more than slight movement up and down the vertical white spaces. Then the vertical shadowy lines, in the middle of these spaces, remain; the horizontal dark lines vanish, as should be the case.

As regards the "vanishing" of a patch looked at, I do not find this to be a correct account of what I observe. I notice that when I suddenly gaze at any one crossing, the crossing dark lines and dark patch at that place take longer to appear; but they do appear in time. Perhaps the "yellow spot" is slower in action than the rest of the retina in questions of fatigue? But these phenomena are difficult to observe, as the eyes soon tire. A very noticeable phenomenon, I suppose an extreme case of fatigue, is the following. When I gaze for a long time, white spaces here and there disappear altogether in a fitful manner, the squares concerned for the time blending. This occurs with monocular vision as well as binocular, as do all the phenomena mentioned. But I think the eyes must be very tired for this to occur.

As regards the question of spacing, I imagine that the steadier the eye-muscles, and so the less the involuntary movements, the narrower might be the white spaces. I have noticed a violet margin round an orange on snow, due to the same causes. It increased when the orange was rolled. The explanation is obvious if the view taken above is right. W. LARDEN.

R.N.E. College, Devonport.

Some Animals Exterminated during the Nineteenth Century.

Re the very interesting article published under the above-mentioned title by Mr. R. Lydekker (p. 252, January 10), may I indicate and correct an error? *Camptolaemus labradorius* is certainly exterminated on the North Atlantic coast of America, as Mr. Lydekker says; but this breed still exists not very far off, but in a somewhat out-of-the-way place, in the island of Anticosti, where M. Paul Combes saw it recently, as he states the fact in his "Exploration de l'Ile d'Anticosti," 1896 (J. André, publisher, Paris). HENRY DE VARIGNY.

Paris.

IN reference to the foregoing letter, it may be mentioned that the duck in question is entered as extinct in the "A.O.U. Check-list of North American Birds," 2nd ed. p. 56 (1895), and no information has subsequently reached this country as to its alleged survival in Anticosti. R. L.

THE PRESERVATION OF PHOTOGRAPHIC RECORDS.

AFTER the article by Dr. W. J. S. Lockyer on the disappearance of photographic images (p. 278) and other references that have been made to this subject, there is no need to dilate upon the importance of the preservation of the vast number of photographic records now being produced in our observatories and laboratories. I would, however, venture to express surprise that the fact established by Dr. Isaac Roberts as to the want of permanence of a silver photographic image appears to have been unexpected, bearing in mind the general procedure that appears to be the rule in the production of such photographs.

Photographic procedure is based chiefly, practically speaking, indeed, entirely, upon "rule of thumb," and if each modification requires a ten years' trial of it to establish its advantage or otherwise, it is at least desirable that more attention should be paid to the principles which govern the production and the permanency of photographs. It is well known that metallic silver is liable to change, yet we cannot get away from the use of silver salts, and these, of course, give silver images. *But silver ought never under any circumstances to be relied on.* The questions that present themselves, therefore, are: (1) how best to preserve the original silver image, and (2) how best to copy it.

It has been suggested to give up gelatine and go back to collodion. But this suggestion appears to be founded on nothing better than the quite insufficient evidence of general experience, and partly, also, on false inference. Metallic silver, we know, is affected by the air, and in a wet collodion plate the silver lies chiefly on the surface of the film, while in the ordinary dry plates it is buried in the gelatine. Moreover, experienced photographers tell us that the image on wet collodion plates gets denser with age. If it does so the image is unstable, and change, however it manifests itself, must be avoided if the photograph is to be accepted as trustworthy. The coarser grains and crystalline character of the image produced on wet collodion would account for its superior resisting power to outside influences, but this alleged superiority has not yet been proved. We cannot go back to collodion, but under any circumstances there appears to be no good reason for expecting any gain in that direction. Gelatine is the medium of to-day, and no evidence of its unfitness has been adduced.

Metallic silver is soluble in such reagents as dissolve silver oxide, if air or an oxidiser is present. Ammonia, potassium cyanide and sodium thiosulphate readily dissolve silver in the presence of air. The oxidation products of developers act as oxidising agents. Ferric oxalate, the product of development with ferrous oxalate, is particularly active in attacking silver, and is practically used for the purpose of thinning silver images. And the coloured products of oxidation of alkaline developers are well known to retard the reduction of silver salts, though apparently they have not been shown to be able to directly attack the metal itself. But it must be remembered that that which produces no appreciable effect in a few months, or even years, may have a disastrous action in a generation, so that the only safe course is to eliminate or exclude every suspicious substance. In short, the photographic film should consist of pure silver in clean gelatine, for anything more than this that is likely to be present will, in all probability, prove deleterious.

There is no difficulty in banishing at once ammonia, ferrous oxalate and potassium cyanide. The ammonia in the developer is replaced by sodium carbonate, an exchange in every way advantageous, the ferrous oxalate by alkaline developers, a change which has already met with general approval, and potassium cyanide as a fixing reagent is practically obsolete. The two great dangers that are not sufficiently appreciated by many photographers are the presence of thiosulphate from the fixing bath and oxidation products from the developer. To remove the first, the usual half-hour of washing is not sufficient, however the water may be applied. There is no particular virtue in running water or in washing contrivances; it is the prolonged soaking in clean water that is wanted. However the washing is done, it is easy to remove the greater part of the thiosulphate; it is the last traces that are hardly, if at all, susceptible to detection by any of the ordinary methods that need attention. If after half an hour it is not possible to detect any thiosulphate in the wash water, a further soaking for an hour and a half, with suitable changing of the water, would not be excessive treatment.

The same washing that gets rid of the fixing reagent washes out the developer and its oxidation products, if the work has been carefully and successfully done. But to ensure this the developer must have sufficient sulphite (sodium sulphite) in it to prevent its discoloration or the staining of the film. The deposition of staining matter should be prevented, as removal is tedious and troublesome. Many published formulæ for developers prescribe an insufficiency of sulphite, and it is not possible to state definitely how much is required, because that will depend on the time taken for development and the amount of sodium carbonate present. But generally, if not always, and certainly when using pyrogallol, the sulphite should be proportioned to the bulk of developer—that is, to the water; it is unsafe to dilute the prepared developer without adding the further quantity of sulphite to maintain its due proportion.

The method generally adopted at the present time to get rid of stains is founded, like so many other photographic methods, on a false basis. The idea is that if a stain disappears, it has gone. The appearance, truly, has gone, but the matter that constituted the stain may remain, and perhaps in a more dangerous form than it was at first. In almost all cases the effect of acids on stains due to oxidised developers is to lighten the colour of the staining matter and to render it insoluble. The action of alkalies is to darken its colour and to render it soluble. Alkaline solutions are, therefore, true clearing reagents, while acids are actually prejudicial, although they appear to effect improvement. It is desirable to carefully avoid the use of any acid solution whatever, and by doing so it will be found that cleaner and chemically purer plates are produced. After developing in an alkaline solution and rinsing the plate, it should be fixed in a solution of sodium thiosulphate made alkaline with sodium carbonate, and then well washed. The washing may be done with plain water, but if there is the slightest trace of colour due to stain, it will be found of advantage to add a little carbonate of soda or a very little caustic soda to the first wash waters. Acid fixing baths should be absolutely eschewed. The very grave risk that accompanies their use is not appreciated, or they would never be recommended.

Having thus obtained a really clean (that is, chemically pure) plate, the exposed surface of the film must be protected in some way to keep the image as much as possible from the air, and also to prevent contamination by the acid perspiration from fingers when handling it.

For this purpose a celluloid varnish will be found a better protection than the ordinary lac varnishes, but whatever is used it is desirable that the gelatine be dried before it is applied. By warming the plate until it is as hot as the hand can bear, and then allowing it to cool to the desirable temperature for varnishing, even though the varnish may have to be applied to the cold plate, the film is probably effectively dried. But what seems to be a much more effective method of preserving the film from outside influences is to cement on to it a cover-glass by

means of Canada balsam, and this is not difficult to do after a little practice.

By thus securing, as far as possible, an image of pure silver in a clean gelatine film, drying it and sealing it up, the photographer will have taken what appear to me to be the best steps possible to preserve the photograph. It may be a little more trouble than the ordinary routine, but hardly so much trouble as is involved in the practice of other photographic methods, such as wet collodion or daguerreotype. But whatever the trouble, nothing short of such treatment as has been indicated will give the photographer the satisfaction of knowing that he has done his best to preserve his plates. I have not referred to toning, although so great an authority as Sir William Crookes has recently referred to it, because a toning process gives a more complex image, and therefore a more difficult one to deal with, but also, and chiefly, because toning is an incomplete operation, and so gives an image of varying composition, and can hardly, by the nature of the action, produce a proportional change throughout the whole image. The fainter detail will be proportionately more affected than the denser parts. Measurements of the effects of the light are thus rendered impossible, or at least doubtful, and so useless.

But whatever care is taken to secure the preservation of the original plate, if it is valuable or likely to become valuable, it alone should not be trusted as the only record of the result it bears. Within a comparatively short time of its production, say within a few months, one or two prints should be obtained from the plate. These prints should be produced in the most simple manner possible in order to avoid personal bias or other possible errors consequent on a multiplicity of manipulations. They should be of the nature of printed-out prints, because a developed print (such as one on bromide paper) allows much scope for variation. Obviously the prints must be permanent. Platinum and carbon prints are the only ones that fulfil these conditions. Both are stated to require "development," but this is a misapplication of the word, or a different application from that which refers to the development of gelatino-bromide plates. The point is that the full chemical effect in both platinum and carbon prints is produced by exposure to light alone, the after treatment only utilising the change. A platinum print is probably more trustworthy as to permanency than a carbon print. The paper used must be of excellent quality, or the sensitive coating would be interfered with, and there appears to be nothing whatever that will affect a platinum image, unless, indeed, it is treated with chemicals that disintegrate the paper at the same time. Platinum prints, however, are not the best agents for showing fine detail or very small differences of density. In this respect they may be improved and much additional brilliancy imparted to them by applying any of the waxing preparations made for waxing prints. For rendering delicate tones, doubtless a carbon transparency would be superior to a platinum print. But if a photographic plate is of such a character that it is desired to preserve its record as nearly as possible for ever, it would not be an undue precaution or an excessive trouble to make two or three platinum prints as well as a carbon transparency from it. If the original plate is to be preserved by sealing it up with Canada balsam, then it should be varnished with a lac or similar varnish for getting the prints. The varnish could then be easily removed, if necessary, before the sealing up of the plate, or a varnish might be used that would be unaffected by the balsam. But on no account whatever must an unprotected film be touched by any platinum paper, carbon tissue, or any paper upon which a printed-out image can be produced, because all such papers contain soluble substances that prejudicially affect the image.

By working on the lines indicated, I think that it would be difficult to set a probable maximum limit to the duration of photographic records. We know how few years are sufficient to produce a measurable deterioration in many of the photographs as at present produced.

CHAPMAN JONES.

A LANCASHIRE COLLEGE.[1]

MR. HARTOG and the authorities of the Owens College are to be congratulated on their work, which owes its origin in part, to quote the words of the preface, "To a request from the committee of the Education Exhibition, held in London in January last, that the authorities of the college should furnish an account of the institution for that Exhibition and for the Paris Exhibition, to which it was preliminary, in part to the desire of the authorities of the college for a record of its development and present condition in celebration of its jubilee."

The introductory chapters deal with the history of the college and its buildings, its government and finance, and its relation to the Victoria University. Then follow details of the classes and lectures, with particulars of the special departments and of other allied institutions, lists of fellowships and prizes, and, lastly, a striking record of original publications by members of the college.

It appears that the earliest attempt to establish a University in Manchester was made in 1640, when Henry Fairfax presented a petition to Parliament in favour of this course. The opposition of the city of York killed the project; the next similar attempt was made in 1877, but the opposition of the city of Leeds led to the establishment of the Victoria University.

Between these dates various efforts were made to promote a college for higher education in the city; none of these, however, met with marked success until, in 1851, the Owens College was founded in accordance with the will of John Owens, a Manchester merchant and spinner.

The first chairman of the Owens trustees was George Faulkner, the friend and partner of the founder, who, it is said on good authority, refused to become Owens's heir, and persuaded him to found a college. Owens's bequest realised about 90,000*l*., and, in accordance with the founder's decision, the income from this was spent mainly on the provision from the first of an adequate teaching staff. To this Mr. Hartog with justice attributes a great share in the ultimate rise of the college. The histories of Owens College and of University College, Liverpool, a sister member of the Victoria University, teach the same truth. Owens College began in a hired house; University College in a disused lunatic asylum; but in both cases the devotion and splendid energy of the staff won in time the confidence of large-hearted men and women in their respective towns, and though the equipment of neither college is yet complete, the laboratories and class rooms, museums and libraries bear striking testimony to the wisdom of those who moulded the institutions in their early days.

Owens College began with five professors and two teachers. To-day its staff consists of thirty professors, thirty-four independent lecturers, and thirty-nine assistant lecturers and demonstrators.

But success did not come at once; the number of day students, which at first was sixty-two, in 1857 dropped to thirty-three; the local newspapers pronounced the scheme to be a mortifying failure. The trustees and the staff, however, held their course, and from 1858 onward the numbers have gone on increasing until, during last session, they reached the total of 1002. A building fund,

[1] "The Owens College, Manchester, founded 1851. A brief History of the College and Description of its various Departments." Edited by P. J. Hartog, B.Sc. Pp. viii + 260. (Manchester: Cornish, 1900.)

which ultimately realised 106,000*l*., was started in 1867, and the first permanent buildings were opened in 1873.

About the same time a fundamental change took place

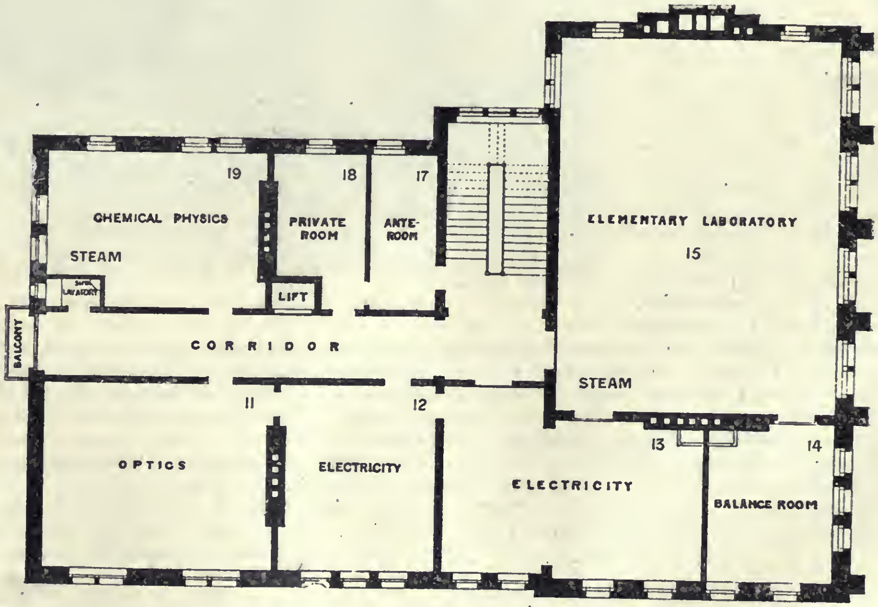
FIG. 1.—Physical Laboratories, Owens College.

in the government of the college, which passed from the trustees constituted by the founder's will to the governors, council and senate appointed under the Owens College Act.

The funds of the college were largely increased by the Clifton bequest of 21,500*l*. for the engineering department and the Beyer bequest of over 100,000*l*., received between 1876 and 1887. Since that date the legatees of Sir Joseph Whitworth have given about 120,000*l*. The capital is now 866,000*l*., of which 418,000*l*. is sunk in land buildings and appliances; almost the whole of this sum is due to private benefactions. The income for the session 1898–99 was 39,000*l*., and of this about 17,000*l*. was derived from students' fees, 12,700*l*. from special endowments, and 4,500*l*. from Government and other public funds.

These figures give some idea of the magnitude of the work done by the college, though in spite of the efforts made there is a continually recurring deficit. Increase in the number of students means a disproportionate increase in laboratories and teaching appliances, which cannot be met by an increase in fees; each extension of buildings involves increased cost in maintenance, rates and establishment. While private generosity has done much, the number of donors is not very large, and the amount received from public funds bears no proper proportion to the work which the college is doing for the city and county. In 1898, the Manchester Corporation contributed 700*l*. for technical instruction and 400*l*. for the museum, while the Lancashire County Council gave 250*l*., to be raised to 500*l*. in the following year.

One other striking event in the history of the college must be noted. In 1877 a memorial, largely supported, was sent to the Privy Council praying for a charter to convert Owens College into the University of Manchester. This was followed by a memorial from the Yorkshire College asking that a charter should not be given to Owens College, but "to a new Corporation, with powers to incorporate the Owens College and such other institutions as may now or hereafter be able to fulfill the conditions of incorporation." This petition proved successful, and the Victoria University received its charter in 1880.



FIRST FLOOR PLAN

FIG. 2.

Owens College became by the terms of the charter

the first college of the University; in 1884 University College, Liverpool, founded in 1881, and in 1887 the Yorkshire College, Leeds, founded 1874, were associated with it as constituent colleges of the University. By its charter women are admitted to all the degrees of the Victoria University. They were first admitted to lectures of the Owens College in 1883, and of the 1002 registered students in 1899—all of whom, however, are not students of the University—126 were women.

Such is, in brief, the history of the first of the University Colleges of the country. Space forbids any attempt at a description of all the present buildings, or of the interior organisation of the college and its relation to the University; much information on these points may be obtained from the book, and the plan and illustrations, which have been prepared with great care and skill, give an admirable idea of the buildings. Among these the most recent are the Christie Library and the physical laboratory, opened by Lord Rayleigh in June last. The Manchester Museum, however, must have a special mention. The nucleus of the collection consists of the specimens belonging to the Manchester Natural History Society and the Manchester Geological Society, transferred to the college with some endowments in 1872. The college is bound to maintain the collections and give the public access to them, free of charge, on certain days. The public lectures, which have become well recognised institutions, are also delivered by the staff and others.

The collections are now housed in splendid buildings and maintained at a total cost of 2700*l.* per annum, of which some 900*l.* is provided by endowment while 400*l.* is a grant from the City Council.

Enough, perhaps, has been said to indicate the magnitude and importance of the work performed for the country by the Owens College; if more proof is needed it can easily be supplied from the volume under review. The ninety pages covered by the record of original publications contain the names of many who have made their mark in literature and science, together with the titles of numerous papers universally recognised as of the highest merit. The authorities of the college did good service to the cause of university education in the country when they prepared a volume such as this for exhibition at Paris. R. T. G.

LORD LILFORD'S LIFE.[1]

THE scientific aspect of the late Lord Lilford's career is, we are informed in the preface to the present volume, to be written by another hand. The task of his sister has been, in the main, to set before the world the character and every-day life of her brother. And a noble theme, admirably carried out, the author has had before her. To a man fond of field sports and an enthusiastic observer of nature, scarcely any more terrible affliction, save loss of sight, can be conceived than to be stricken down in the prime of life by a malady which rendered him for the rest of his days a helpless cripple dependent for every want upon the attention of others. And yet how nobly and how patiently was this affliction borne by the subject of this pathetic memoir! Of course, every alleviation that money could purchase or affection suggest was at his command, but even so the trial of existence under such distressing circumstances must have been a heavy burden. How much was done by the late peer to advance the science he loved so well, and to ameliorate the lot of his fellow sufferers in humbler walks of life, those who knew him intimately can alone tell. The story of such a life is a lesson and a bright example to us all, and it should thus attract many readers besides personal friends and those interested in ornithology.

But in a journal like NATURE, attention must be directed to scientific rather than to moral attributes, even in a memoir which purports to treat chiefly of the latter. From his earliest days Lord Lilford appears to have displayed a remarkable fondness for animals, and throughout his life the observation of their habits seems to have afforded him the most intense delight. To those who are not endued with this love of living creatures it is difficult to realise how strong is its development in others. Although in earlier days a keen sportsman, Lord Lilford states he experienced more delight in watching the movements of wild birds than in shooting them; and in the collection at Lilford it was his aim that the feathered captives should enjoy as much liberty and space as was compatible with deprivation of complete freedom. The sight of a captive eagle moping in a cramped cage, with draggled feathers and unclean surroundings, was absolutely hateful to his sensitive nature; and the collection of eagles and other birds of prey at Lilford afforded an example, as regards mode of treatment, to the menageries of the world. But cranes were the birds which formed the great specialité of the Lilford collection, and only a

FIG. 1.—A bittern in the crouching attitude (from "Lord Lilford's Life").

[1] "Lord Lilford, Thomas Littleton, Fourth Baron." A Memoir by his sister, with an Introduction by the Bishop of London. Pp. xxiii + 290. (London: Smith, Elder and Co., 1900.) Price 10*s.* 6*d.*

bird lover can fully realise the joy of the owner at the completion of the series, in 1894, by the arrival of a specimen of the wattled species.

Lord Lilford, in his published letters, constantly deprecates his own claims to be regarded as a scientific ornithologist; but, altogether apart from his beautiful work on British birds, we venture to think that the work of the field-naturalist, which he did so much to advance, is at least as important as that of the systematist. Not that the late peer was in any way out of sympathy with the latter line of research; quite the contrary, as is demonstrated by the letter from Mr. O. Thomas, referring to his generous aid in assisting to complete the collection of European mammals in the British Museum with a view to a future exhaustive work on the subject. In addition to his energetic efforts on behalf of bird protection (including the prohibition of indiscriminate egg-collecting), Lord Lilford displayed especial interest in the fauna of Spain—an interest which has been happily commemorated by the name assigned by Mr. de Winton to the Spanish hare, which has been recently found entitled to specific distinction.

In the main the letters which the author of the memoir has selected for publication help in forming a true estimate of the character of their writer; but, in our opinion, some of those to artists and taxidermists referring to minute details in their works might advantageously have been omitted. One of the most interesting portions of the volume is the concluding chapter, which is made up by extracts from Lord Lilford's notes on his own collection of living birds and other animals. And the interest of this is much enhanced by the beautiful sketches of birds in the collection from the talented pencil of Mr. Thorburn, one of which we are enabled to reproduce. One of the objects dear to Lord Lilford's heart was to obtain portraits of birds in their natural and characteristic attitudes, and thus to improve the system of mounting specimens in museums, where it was formerly the exception to find a species in anything approaching a natural pose.

Apart from the noble example of his life to mankind in general, the loss to natural history of a man like Lord Lilford is one that will not easily be replaced, as, unfortunately, but few of those endowed with wealth and leisure display any inclination to follow in his footsteps.

R. L.

PROF. J. G. AGARDH.

JACOB GEORG AGARDH, the great Swedish phycologist, was born at Lund on December 13, 1813. His father was the celebrated Dr. Carl Adolf Agardh, professor at Lund University, and afterwards bishop in the diocese of Karlstad. The elder Agardh was the author of the "Synopsis Algarum Scandinaviæ," the "Systema Algarum" and the "Species Algarum," which laid the foundation for the brilliant work accomplished by his son.

Jacob Agardh entered as a student in the University of Lund in the year 1826, became doctor of philosophy in 1832, docent in 1834 and demonstrator of botany in 1836. In 1847 he became extraordinary professor, and in 1854 he was made ordinary professor, which post he held till 1879, when he retired.

His first paper, on Pilularia, was published in 1833 and was followed by several others on botanical subjects, mainly systematic. In 1836 appeared his first paper on algæ, and from that time till shortly before his death he continued with unfailing activity to publish papers and books on marine botany. The greatest work of his life was the "Species, Genera et Ordines Algarum," in which he laid down for the first time the lines of a natural system of classification in algæ. The English phycologists, Greville and Harvey, had helped to pave the way for this monumental work, and the elder Agardh had prepared some of the ground in his "Species Algarum" already mentioned. Dr. Kützing in Germany had already begun, in 1845, his "Tabulæ Phycologicæ, but it remained for Jacob Agardh to bring into order the many genera of marine algæ which had been left untouched, and to divide up the whole group into series, orders and genera. It is difficult for a worker in these days to realise the chaos in which the whole subject of algæ was involved when Prof. Agardh began his great work. Records were scattered throughout botanical literature, and it is no marvel that a species was described more than once through ignorance of an already existing diagnosis. The "Species, Genera et Ordines" brought together all the hitherto described species and added many new ones. These were arranged according to a natural system, and their synonymy, literature and geographical distribution were appended. From that time all work on algæ was straightforward, and although in time this book of Prof. Agardh may be superseded, it will long remain the ground plan of systematic phycology. The first volume dealt only with Phæophyceæ, and was published in 1848. Four volumes on Florideæ followed, of which the last is a revision and enlargement of the first part. The Corallineæ were worked out by Prof. Areschoug and included in the third volume of the work. In the introduction to the last volume, published in 1876, the author states that he has treated of "the disposition and description of forms" rather than "of the organs which have been considered of the greatest importance"—the trichogyne and antheridia, and the functions of these organs. This statement is specially interesting in regard to the classification of Prof. Schmitz, which is now so largely followed. There the differences which form the groundwork of the classification consist in the various forms of development in the carpogonium after fertilisation has taken place, thus forming a system which, however correct scientifically, is wholly unpractical for systematic workers. (It is, however, only fair to add that in this respect the system was perhaps only left incomplete through the premature death of its author.) In Prof. Agardh's system the algæ are classified according to their mature form, and indeed, as is only natural, the whole of his earlier work makes more of macroscopic, or at least of the less minute characters, than is usual in these days. In some cases this led him into error, but, on the whole, it is interesting to see how much his work is confirmed in the main points by the investigations of later botanists working on different lines.

In 1872 there appeared the first part of "Till Algernes Systematik," which was published at intervals till 1890, and dealt at length with genera in all groups of algæ. The treatment of the genus Caulerpa has been alluded to by Mdme. Weber van Bosse in the dedication of her monograph of this genus, in which she declares Prof. Agardh to be the first to give a natural system to Caulerpa and to open the road for a special study of these algæ. These words apply to many another genus as well. In 1879 an important work, "Florideernes Morphologi," appeared, followed by "Species Sargassorum Australiæ" in 1889; and in 1892, when in his eightieth year, a new work was undertaken entitled "Analecta Algologica." Parts were issued at intervals, and, although it was supposed a few years ago that the aged botanist had finished his work, and that the "Analecta" had come to an end, he still continued writing, and even published a part so late as last year. The work of these years cannot be ranked so highly as that of his middle life; but nothing can ever detract from the brilliancy and lasting worth of his work in earlier years.

Prof. Agardh was referee to Kew for algæ, and many specimens in that herbarium bear their names in his handwriting. In later life he received much material

from Australia, where Miss Hussey and others collected for him. The herbarium of the late Mr. Bracebridge Wilson, which was bought by the British Museum in 1896, had been referred to Prof. Agardh, and some of his notes are found in Mr. Wilson's handwriting copied on the sheets.

Of the kindness of the late professor it is possible to speak from personal experience. He was always ready to help and advise any student of algæ; he would examine a plant sent to him and endeavour to identify it, and, when the circumstances warranted the risk, he would send his own valuable type-specimens for examination. Never did Prof. Agardh fail to give of his best, though from his position in the world of phycology requests must sometimes have been numerous, and leisure uncommon. So late as December of last year it was my privilege to receive from him on loan a type-specimen of one of his species of Siphoneæ, and for the first time there was in his letter a strong vein of anxiety concerning the alga, and an urgent request that it might be speedily and carefully returned. The whole letter showed most markedly the advance of age, and the evident relief when the alga reached him safely on its return was almost touching. Quite shortly afterwards came the news of his death on January 17 of this year.

His knowledge of English was excellent, and he wrote it well and idiomatically.

His herbarium was given by him some years ago to Lund University, the home of his own work and of his father before him.

Medals and honours came to him from all sides. He was member of the Vetenskaps Academy, honorary member ot the Göteborg Scientific and Literary Society, as well as of the Scientific Society of Upsala and the Agricultural Academy and Physiographical Society in Lund. In 1862 he was appointed to confer the degree of Ph.D. at Lund, in 1879, at the jubilee of the Copenhagen University, he received the honorary title of doctor of medicine, and in 1883 he became a "jubeldoktor" of philosophy. In 1893 he was decorated with the Grand Cross of the Nordstjern Order, in 1886 the Vetenskaps Academy presented him with the Letterstedt prize for original work, and in 1897 he received the gold medal of the Linnean Society. He was also knight of the Prussian Order Pour le Mérite.

As delegate for the University of Lund he attended the two last sessions of the Ecclesiastical Council, and after the change in the representation he was member for the town of Lund in the second Chamber from 1867-1869 and from 1870-1872. He was also member of the Mint Committee of 1872.

He married, in 1848, Margareta Helena Sofia Meck, who survives him; and he leaves two sons, one of whom continues the family tradition of being attached to the University of Lund. E. S. B.

PROF. ELISHA GRAY.

IT is with great regret that we learn of the death of Prof. Elisha Gray on January 21. Prof. Gray was born at Barnesville, Ohio, in 1835; he was apprenticed to a carpenter, and during the time of his apprenticeship he studied physical science. At the age of twenty-one he went to Oberlin College, where he worked for five years, and at which he afterwards became professor. Prof. Gray first turned his attention to electrical invention when at the age of about thirty; he then invented a self-adjusting telegraphic relay. This was soon followed by other inventions of telegraphic apparatus. In all he took out about fifty patents, mostly dealing with telegraphy and telephony; one of the latest of these, and one of the best known, was the telautograph, a telegraphic apparatus for transmitting handwriting to a distance. At the time of his death he was engaged in carrying out experiments on a method of marine signalling with electric bells by which the sounds could be transmitted several miles through the water. In the course of these experiments, we understand from an American contemporary, he caught a chill which caused his sudden death.

Prof. Gray's name will be perhaps best known and remembered in connection with the invention of the telephone. On February 14, 1876, he lodged a caveat with the American patent office for the invention of a telephone. On the same day, but a little later, Graham Bell lodged a caveat for his similar invention. Bell was, however, the first to perfect his instrument, and in consequence Gray yielded to him in the dispute as to priority which arose, and the matter was compromised by the purchase of both patents by the same company. In later years, in the course of legal cases which arose in connection with the Bell patents, disclosures were made by which Gray was led to believe that his caveat had been betrayed to Bell by one of the patent examiners. Whether this actually was true or not seems to be uncertain, but in any case Gray firmly believed in its truth, and his later years are said to have been embittered by the thought that he had been cheated out of the money and credit he deserved. In 1878 his work in connection with the telephone was recognised at the Paris Exhibition, and he was decorated with the Legion of Honour. In 1893 he was Chairman of the International Congress of Electricians at the World's Fair at Chicago. He was the author of a popular book on electricity, and also of several papers communicated to scientific societies.

THE INDIAN ENGINEERING COLLEGE, COOPERS HILL.

A DEPUTATION waited on Lord George Hamilton on Tuesday last with respect to the recent dismissals from Coopers Hill College, and in support of the following memorial, with 374 signatures attached, including the names of the principal leaders of science in the country. The deputation was introduced by Lord Kelvin, and there were present Lord Lister, Lord Rayleigh, Sir H. Roscoe, Prof. Armstrong, and Dr. G. J. Stoney, who spoke in relation to the question; Sir F. Bramwell, Sir F. Abel, Sir Norman Lockyer, Sir William Crookes, Prof. Carey Foster, Prof. Meldola, Prof. Le Neve Foster, Prof. Everett, Prof. Perry, Prof. Poynting, Dr. G. Johnston, and many others.

Memorial to the Right Honourable the Secretary of State for India.

The correspondence regarding Coopers Hill College which has been published in the *Times* of January 3, 1901, which includes Sir Horace Walpole's letter to Colonel Ottley of December 14, 1900, and Colonel Ottley's letter of December 17, 1900, has caused a painful shock to those engaged in higher education throughout the United Kingdom, and to all who are interested in the training of engineers.

This correspondence relates to the sudden and arbitrary dismissal of able and distinguished scientific teachers, who have been doing duty in the College for periods of from nine to thirty years, and the value of whose past services is at the same time officially recognised.

Such arbitrary dismissal is likely to affect adversely the cause of scientific teaching in the United Kingdom. It cannot fail to injure the future of the College. During the correspondence which has ensued it has become apparent that the teaching staff have no voice in the educational policy of the College, and are not consulted when any change in the curriculum is contemplated. We wish to draw the attention of the Secretary of State to this unsatisfactory state of affairs, which must militate against the success of the College as an educational centre.

The sudden dismissal is action of a kind which we were not prepared to expect in any institution under the control of the British Government; and we think that the seven members of

the staff who are required to retire at three months' notice are justified in asking for the inquiry into the working of the College, for which they have petitioned in their memorial of Dec. 27, 1900.

We therefore desire to express our hope that the Secretary of State for India will see his way to grant their request, and to suspend proceedings until an adequate inquiry by competent persons shall have been held.

Lord Kelvin, as reported in the *Times*, said he represented 374 signatures with respect to the seven dismissals from the Engineering College. He had received letters of apology from Sir Batty Tuke, who expressed the conviction that a great injustice had been done; from Sir Richard Jebb, who expressed the opinion that the dismissals were harsh and derogatory to science and deterrent to good men; from Col. Milward, from Prof. Oliver Lodge, who said the professors had been treated like pawns; Sir Douglas Fox wrote as an ex-governor of the college who had received no notice of this proposed "drastic change." Sir Douglas Fox said that certain changes had been suggested to the board of visitors, and among these the supersession of two out of the staff; but he was astonished to find seven men dismissed.

Lord George Hamilton said that all who were present signed the report. Sir D. Fox was wrong.

Lord Kelvin said he had read in the *Standard* that the board of visitors were unanimous. But the letter of November 2—the origin of the change—was founded on recommendations of the board of visitors at that date, and those recommendations did not propose that seven gentlemen should be dismissed. It was clear that the general public looked upon the board of visitors as the governing body, and in so doing were resting on a broken reed. The board appeared to have had little to do with the matter. The object of the memorial was threefold—(1) To protest earnestly in the public interest against the proposal for the sudden and arbitrary dismissal of seven out of fourteen of the staff of the college; (2) to call attention to the continued prosperity of the college and the need for reform in the curriculum; (3) to express a hope that the Secretary of State would countermand these changes, until adequate inquiry was made and they were shown to be necessary for the good of the college. Sir Horace Walpole rested the case on economy. Now the cost of the whole scientific staff was 7970*l.*, and the fees were 22,143*l.*, or about 36 per cent. of the receipts for tuition. When the number of students did not fall below 121 there was a surplus; and thus retrenchment could hardly be the real reason. The proposed change would effect a saving of 2750*l.*; and certainly economy at the expense of efficiency was a great mistake. The dismissal was sprung upon the threatened persons, and was certainly not creditable. One of them—an old pupil of his own—described it as a blow in the dark, and said he could not understand it. It might, his correspondent said, have been desirable to reduce the number, but it was inconceivable that the abolition of the professorships of chemistry and of physics and of the posts of demonstrator of physics and of instructor of physics should have been recommended by the board of visitors. The chemistry for the future, it appeared, was only to be such as should enable engineers to understand the statements of results of professed chemists. There was to be no electricity or magnetism. Did the authors of this scheme know anything of the requirements of engineering? Electrical engineering was still on the list. That was an applied science; and thus we had a British Government college, teaching the application but not the fundamental principles of a science. Was that worthy of this country? The public might fairly expect that the present staff would, at all events, continue to the end of the present year, as entering students could hardly be deprived of adequate teaching of the full curriculum of subjects. The Secretary of State himself had borne testimony to the excellence of the college—even so recently as last year. There might have been some falling off, but a high standard was kept up. There had, no doubt, been some complaints, and from India the telegraphy course was found fault with. But that course was not intended to be exhaustive, but was to be supplemented by other members of the staff. But there was no complaint about any candidate who entered the Public Works Department of India. In the telegraph department two gentlemen were admitted into the public service whom Coopers Hill refused to certify. He earnestly hoped the noble lord would let the existing prospectus be that of 1900, and that Colonel Ottley and his staff would contrive to work together and remove causes of mutual friction. Discipline, law and order were doubtless necessary, but they might be harshly enforced; and of these gentlemen there was no recorded complaint.

Lord Lister said there were two questions; one the manner of the dismissal, and the other the expediency of the changes in the curriculum. On the first he needed to add nothing to what Lord Kelvin had said. Such a step was a great discouragement to those who wished to follow a scientific career; such appointments were rare, and a man's lifework might be abruptly stopped by such treatment as was being accorded. In his own profession he had to lament the tendency of examining bodies to abolish or minimise scientific training.

Lord Rayleigh said that unless such educational posts under the Crown were reasonably secured, there would be great difficulty in getting good men. Of the men to be dismissed he had personal knowledge of some, and Prof. McLeod was a man of world-wide repute among chemists.

Sir Henry Roscoe was sure that Lord George Hamilton had acted for the best: but they were convinced that he was mistaken. The dismissal of these men without notice was subversive of the interests of science and prejudicial to the college itself.

Prof. H. E. Armstrong said that these gentlemen's colleagues felt the action of the Government to be a positive affront. None of the signatories to the memorial, he thought, objected to a careful revision of the subjects and methods of the college; but that was another matter. If the new teaching of chemistry was to be such as had been described, it would be better to drop the subject altogether. If our engineers of India had been competent chemists they would have been able to advise the indigo planters and prevent the transfer of a trade of three millions to German planters.

Dr. G. J. Stoney said the letter of appointment to Coopers Hill was that it was tenable so long as the work was satisfactory; but with the proviso of three months' notice, without cause assigned on either side. The substantive clause and the proviso ought to have been read together, and the proviso ought not to render the words of the clause nugatory. The proviso was only to prescribe the method of dismissal if the work was not efficiently done. The interpretation of the proviso acted upon by the authorities virtually overrode the words of the substantive clause.

Lord George Hamilton, in replying to the deputation, is reported by the *Standard* to have said that as soon as he received a memorial to which were attached such distinguished signatures he felt it his duty to take the first opportunity of meeting the gentlemen who had expressed such interest in the future well-being of Coopers Hill College. He was under the impression when he read the memorial that it was based entirely on certain suppositions, and the more he listened to the speeches the clearer was it to him that the great mass of the signatories had, under some misapprehension, attached their names to the memorial. He had the honour of seeing a number of gentlemen whose names were household words all over the world as investigators in original science, and who had made discoveries of the utmost benefit to mankind. He ventured to point out that the memorial as drawn up would reverse the process by which they had achieved fame. That fame had been attained by an investigation into the phenomena of facts, and this memorial asked for an inquiry, but every speaker had with the utmost confidence pronounced an opinion upon the subjects on which he asked for investigation. He did not in the least find fault with the signatories, who had been misled, nor could he attach any blame to himself. The Coopers Hill Staff had adopted a very unusual and inconvenient course. They had a perfect right to protest against any action which they thought prejudicial to their personal interest, and to press the India Office to reconsider the question, but they sent a memorial to himself, and before it was possible to consider it they at once embarked in a newspaper agitation, with letters written by the gentlemen themselves or by their friends. He wished to explain very fully the reasons for the action the India Office had taken, and then he would ask the deputation whether, when the facts had been brought before them, the India Office could have acted otherwise than they had done. He then gave a short history of the foundation of Coopers Hill. From the outset the College had been a financial failure, and it had placed a considerable burden upon the revenues of India, and until quite recently there was a considerable deficit

in the revenues of the College. In 1895, Mr. Fowler, his predecessor, appointed a Committee to inquire into the financial position of Coopers Hill, which unanimously reported that the teaching staff of Cooper's Hill was out of all proportion to the number of students they had to teach, but there was then no inquiry made into the efficiency of the education given. Shortly after he became Secretary of State for India he came in contact with various members of the board of visitors, and he was warned that the College was very far from being in a satisfactory state, either as regards teaching or discipline, and that the best thing would be to abolish the College altogether. He declined to do that, and thought they ought to try to improve the College before attempting to abolish it. Nine months after Colonel Ottley became president of the College he presented a report in accordance with the instructions of the India Office. The memorial asked for an inquiry by competent persons. The inference rather was that whatever inquiry had been made was inadequate and had not been made by competent persons. His lordship quoted the names of the gentlemen forming the board of visitors, and mentioned their various qualifications, adding that there had not been a change made in the College that had not had the unanimous approval of the gentlemen to whom he had referred. Those gentlemen had gone through every proposition made to them, and it seemed to him a little unreasonable on the part of Sir Douglas Fox to try to convey to the public what passed at a meeting at which he was not present. The report which Colonel Ottley made showed a very unsatisfactory state of affairs at the College, and he (Lord George) was sorry to have to publish it. It was self-evident that the state of things was such that they could not tolerate. The deputation had come to him because they believed that one-half of the teaching staff had been summarily dismissed. He was afraid, therefore, he must detain them by going through each particular case. The reasons were so self-evident in each particular instance that he thought they would all agree that the Council had no option but to do what they had done. His lordship then gave details of the proposed scheme of retrenchment, mentioning the names of Mr. Reilly, Mr. Hurst and Prof. McLeod, and the gratuities and pension granted them. He now came to the four displacements, which were the result of changes that were to take place in the teaching at Coopers Hill. He had no doubt it would surprise gentlemen to learn that though electrical engineering had made enormous progress in recent years, it was not an obligatory subject at the College, and was hardly taught at all. They proposed to make it a compulsory subject, and to bring in a gentleman of high attainments from outside, who would be assisted by the very best lecturers that could be obtained. These changes necessitated the retirement of Mr. Stocker and Mr. Shields, who would be compensated. The two cases which were left were probably the most important of any of the changes they proposed. Everybody who had looked into the teaching at the College was of opinion that the right course was to place the whole course of engineering in the hands of one professor, with a competent assistant, and that being so, they were bound to appoint to the post the most competent professor for the position. That gentleman was Dr. A. W. Brightmore, and his appointment necessitated the retirement of Mr. Hearson and Mr. Heath, to whom pensions have been granted. The upshot of the whole matter would be this—there would be an increase in the hours of work in class and lecture from twenty-six to thirty-two, that the standard of the entrance examination would be raised, electricity as a subject would be thoroughly taught, outside examiners would be appointed, and the whole course at Coopers Hill would be brought, as far as practicable, into accord with modern engineering requirements. He had stated exactly the reasons and courses which had induced them to take the action they had done, and he thought they would see it was an impossibility for them to reopen the subject, or have a fresh inquiry. The noble lord went on to say: I often wonder how it comes to pass that when we spend so much money on our educational system, which in every branch is the most expensive in Europe, that we attain such unsatisfactory results. In every newspaper devoted to education in recent years there have been complaints by parents and others, pointing out the necessity of improvements if we are to hold our own. What is the main obstacle? What is the great impediment to all educational reform? I pass to a subject on which we shall all be in harmony—the system of education prevalent in our public schools. I read the other day an instructing report drawn up by a gentleman who had thoroughly investigated the system of teaching in force at the preparatory schools for the great public schools, and this was his comment:—"That in these preparatory schools the curriculum in force for boys of from twelve to thirteen is as follows: Hours per week: Eleven for Latin, five for Greek, three-quarters of an hour for English, two for history and geography, three for French, and six for mathematics," and he goes on to say that "this course of study is obviously faulty, though the fault is not with the preparatory schoolmasters, who are quite alive to the need of reform, and prepared to admit it when the public schools, which in this country depend upon the Universities, will allow them to do it." Why will not the Universities and public schools allow this ancient and antiquated system to be changed? Because the personal interests of those who teach classics stand in the way, and if you come to me, then, in the interests of scientific teaching for the future, are you not rather emphasising and accentuating the difficulty that must always face educational reform if the personal interests of those who teach are to be predominant over every other consideration? And there is another consideration which I think will come home to you—that no college is worth maintaining unless discipline and subordination can be infused into the students. I think it is very unfortunate that these gentlemen began to agitate in the way they did. The result has been that the students of the Coopers Hill College have begun to write to the newspapers, and I know of one very improper letter that was repudiated by the older students. I am most anxious to treat all the gentlemen at Coopers Hill College with the utmost consideration, but I am quite determined—and in that I express the unanimous opinion of the Council—that, so long as we are responsible for Coopers Hill College, we are determined to maintain discipline and subordination there. I should be exceedingly sorry if you went away with the impression that we had been harsh or discourteous or arbitrary towards the gentlemen who are to be dismissed; but we entered into a contract which necessitated our giving them notice if we wanted to dispense with their services. We are compelled to give them notice, and I do not see how we could have acted otherwise. I hope always to treat all gentlemen of scientific attainments with the utmost consideration, and to pay all attention to their wants; but it must be self-evident to everybody who dissociates himself from the subject under discussion, that the Government cannot for a moment admit that any gentleman who happens to be engaged in scientific teaching is to have such vested interest in the permanence of the post he holds that he is to hold it regardless of the terms or conditions of the engagement into which he has entered. Such a position is an impossible one, and, therefore, I cannot hold out to you any hope of going back on the decision which has been conveyed to these gentlemen. What we did we did deliberately, and after the fullest examination, and after we had availed ourselves of the advice of the best authorities at our disposal. Any suggestions that may be made by the gentlemen before me with regard to improving the curriculum and time-table at Coopers Hill or enabling the president of the College and the board of visitors to establish harmonious relations with the teaching staff will receive our most careful consideration. But we cannot undo what we have done, and, therefore, though the statements I have made will not be satisfactory to you all, I cannot help thanking you for the interest you have taken in Coopers Hill College, and I hope that if ever it becomes again the subject of discussion between us, I shall be able to show that the changes which we have made will result in improving the utility of the College and bringing it fully up to modern requirements.

Lord Kelvin thanked the noble lord for his courtesy in receiving the deputation, but expressed disappointment at the nature of his reply.

The deputation then withdrew.

NOTES.

PROF. J. A. EWING, F.R.S., has been elected a member of the Athenæum Club under the provisions of the rule which permits of the election of persons "of distinguished eminence in science, literature, the arts or for public services."

THE French Association for the Advancement of Science will hold its annual meeting this year at Ajaccio in Corsica, probably about the middle of September, under the presidency of Dr. Hamy.

WE deeply regret to see the announcement that Prof. Max von Pettenkofer, of Munich, distinguished for his work in hygiene and metabolism, shot himself on Sunday in a fit of depression. He was eighty-three years of age.

THE Institution of Naval Architects has awarded a gold medal to Prof. G. H. Bryan, F.R.S., for his paper on "Bilge Keels," read last year, and printed in abstract in NATURE of June 11, 1900 (vol. lxii. p. 186).

WE learn through the *Lancet* that a disastrous fire has occurred at the Pathological Institute in Berlin, and that the most valuable portion of Prof. Virchow's private museum has been destroyed. The loss of the anthropological collection made in the Philippine Islands by Prof. Jagor is especially regretted.

AT the annual general meeting of the Royal Astronomical Society on Friday last, it was decided by a large majority to hold future meetings at five o'clock instead of eight o'clock as hitherto. Dr. J. W. L. Glaisher, F.R.S., was elected president of the Society. Mr. Choate, the American Ambassador, was present at the meeting, and received the gold medal awarded to Prof. E. C. Pickering.

THE Brussels Academy of Sciences has awarded a gold medal, of the value of six hundred francs, to M. F. Swarts, for a memoir on the subject of carbonates of an element the compounds of which are little known. A similar award has been made to Prof. J. Massart, for a memoir on the nucleus of Schizophytes, and the Edouard Mailey prize of one thousand francs, for assistance in the extension of the knowledge of astronomy in Belgium, has been awarded to M. F. Jacobs, the founder of the Société Belge d'Astronomie.

A COMMUNICATION from Prof. A. Newton, F.R.S., relating to some bones of the crane found in excavating the Lynn Docks in the year 1867 or 1868, and now in the Gunn collection in the Castle Museum, was read at the last meeting of the Norfolk and Norwich Naturalists' Society. Prof. Newton gave some interesting information as to the remains of this bird which have been found in the peat of the Fen district, and mentioned other bones in the collections at Cambridge. Mr. Southwell read a paper on the crane in East Anglia, giving a summary of what is known from old authors with regard to the bird as a resident in the Fens, and tracing, as far as he was able, its extinction as an inhabitant. The crane now only visits Norfolk on very rare occasions, at the time of its periodic migrations, the last occurrence being in 1898, when four of these birds visited the neighbourhood of Cley and Runton.

A DEVELOPMENT of Mr. Marconi's system of wireless telegraphy was announced by Prof. J. A. Fleming, F.R.S., on Tuesday, in the course of an address to the members of the Liverpool Chamber of Commerce. Mr. Marconi's private work is carried on chiefly between stations at St. Catherine's, Isle of Wight, and Poole, in Hampshire. The line joining these stations is crossed by the Admiralty line between Portsmouth and Portland, but Mr. Marconi has been able to send and receive two messages simultaneously between his stations without in the least interfering with the Admiralty tests. He has also established a station at the Lizard, in Cornwall, which is 200 miles over sea in a direct line from St. Catherine's. Prof. Fleming said he had Mr. Marconi's permission to announce in public for the first time the result of the latest experiments. Setting up his improved apparatus and a mast 160 feet high, Mr. Marconi accomplished the astonishing feat of sending wireless messages between those two places on the first day of the reign of King Edward VII. Since then Mr. Marconi has established perfect communication without wires between the Lizard and St. Catharine's in both directions, and he can now receive two or more messages at once at each place.

TO give men of science and others the opportunity of visiting lands and places of particular interest, a number of cruises have been made in connection with our contemporary, the *Revue générale des Sciences*. The eleventh excursion will be to Sicily, Naples, Pompeii, Salerno, the ruins of ancient Paestum, and neighbouring places, at Easter, the party leaving Marseilles on March 31 and returning on April 16. The scientific guides of the party will be MM. G. Perrot and E. Bertaux, and at each place other distinguished men specially familiar with the objects, buildings, monuments and natural phenomena of interest will cooperate with them. The object of these excursions is more the study of lands and peoples, ancient and modern civilisation, scientific institutions and objects of archæological importance, than casual sight-seeing, and every effort is made to enable the members of each party to derive the fullest advantage from the visits. A programme of the Easter arrangements can be obtained from M. Louis Olivier, *Revue générale des Sciences*, 22, rue du Général-Foy, Paris.

THE accompanying illustration shows the arms recentl granted to the University of Birmingham. The two-headed lion is taken from the arms borne by Sir Josiah Mason, the founder of Mason College, now absorbed in the University, and the mermaid was his crest. The University, having no helmet, needs no crest. Following the usual university pre-

cedent, the motto is placed on an open book, and not on a ribbon below the shield. The arms are thus described in the grant:—Per Chevron the Chief per pale Gules and Azure in dexter a Lion rampant with two heads in sinister, a Mermaid holding in the dexter hand a Mirror and in the sinister a Comb Or the base Sable charged with an open book proper with two buckles and straps and edges of the third inscribed "PER ARDUA AD ALTA" of the fourth.

A REUTER correspondent at Cairo reports that Sir John Aird and Sir Benjamin Baker have completed their visit of inspection to the great engineering works at Assuan, where the immense dam to hold up the waters of the Nile is being constructed. The total extent of the dam is one mile and a quarter, of which one mile and an eighth of the foundation is finished. Temporary dams enabling the remaining section to be put in are now carried across the channel. The dam is pierced with 180 openings, about 23 feet high and 7 feet wide, which openings are controlled by steel sluices. The work for the latter is now well advanced. The discharge through these sluices at high Nile may reach 15,000 tons of water per second. The navigation channel and chain of locks are equally advanced with the dam itself, and the lock gates will also be in course of construction in about three

months. Unless anything unforeseen occurs the reservoirs will be in operation for the Nile flood of 1903. At Assiut the great regulating dam across the Nile approaches completion, the foundations being practically all in position, leaving a portion of the superstructure to be completed. The sluice openings here number 119, all 16 feet wide. This dam is somewhat similar in principle to the well-known barrage near Cairo, but the details of construction are entirely different, as the foundations are guarded against undermining by a complete line of cast iron and steel-piling above and below the work. The barrage itself is constructed of masonry instead of brickwork as at the old barrage. Although the Assiut barrage is overshadowed by the greater magnitude of the Assuan dam, it will, doubtless, rank second as the monumental work of Egypt.

WE have received from the Government Astronomer of Western Australia the meteorological report of the observations made at the Perth Observatory and other places in that Colony during the year 1899. Observations have been made since 1876 in the botanical gardens at Perth, and are still continued; for practical purposes these are very valuable, but since the year 1897 much more complete and trustworthy observations have been made at the new observatory. Most of the outlying stations have been inspected, and the observations now appear to be taken with much more care and regularity than in former years. Owing to the absence of any well-defined natural features, the Colony has been subdivided into one-degree squares, and the rainfall values of each square are shown very clearly in monthly and yearly maps. Other maps show, equally clearly, the mean monthly barometer and temperature, and the mean maximum day and minimum night temperature by the usual method of isobars and isotherms. A set of four platinum resistance thermometers has been sunk in the earth at Perth, and appear to give very satisfactory results. Morning and evening weather forecasts are issued, and have been remarkably correct, the amount of complete success reaching 82 and 89 per cent. respectively.

THE Palæontographical Society announces that monographs on the following groups of fossils are in course of preparation, and will be published by the Society: the Carboniferous Lepidodendra, by Dr. D. H. Scott; the Cycadeæ, by Mr. A. C. Seward; the Graptolites, by Prof. Lapworth, assisted by Miss Elles and Miss Wood; the Fishes of the Chalk, by Dr. A. S. Woodward; the Reptilia of the Oxford Clay, by Dr. C. W. Andrews; and the Cave Hyæna, by Mr. S. H. Reynolds. The volume issued by the Society for 1900 contains the Cretaceous Lamellibranchs, by Mr. H. Woods; the Carboniferous Lamellibranchs, by Dr. W. Hind; and the Carboniferous Cephalopods of Ireland, by Dr. A. H. Foord.

MR. HUGH J. L. BEADNELL, of the Egyptian Geological Survey, has published a brief account of the Eocene and Cretaceous series in the Libyan Desert and Nile Valley (*Geological Magazine*, January 1901). He has also expressed his opinion that the Nile Valley in Egypt, hemmed in as it is by lofty cliffs, was in the main brought about by faulting and disturbance in Lower Pliocene times. After the deposition of the Pliocene strata a gradual elevation led to the final retreat of the sea, and the valley then became the site of a series of freshwater lakes. In later Pleistocene times the then youthful Nile commenced its career by carving out a channel in the valley deposits, before, owing to changed conditions, it began depositing layer upon layer of Nile mud.

THE pre-Cambrian igneous rocks of the Fox River Valley, Wisconsin, are described by Dr. Samuel Weidman (Wisconsin Geol. and Nat. Hist. Soc., *Bulletin* 3 of Scient. Ser. No. 2). Three areas of these rocks are noted, and they represent various phases from old volcanic flows to masses of deep-seated origin. In the area of the Utley meta-rhyolite, metamorphism has taken place under static conditions, no cleavage is developed, and the alteration has been produced through chemical change without the aid of mechanical deformation. On the other hand, the Berlin rhyolite-gneiss has been subjected to extreme deformation, the original rhyolite being mashed into a gneiss; while the metamorphism of the Wanshara granite has been in part static and in part mechanical, cleavage has been developed and granulation of the quartz has taken place to some extent.

A FLORA of Staffordshire, by Mr. J. E. Bagnall, is being issued as a monthly supplement to the *Journal of Botany*.

THE Report on the Botanic Gardens and Domains, New South Wales, for the year 1899, gives an account of the new herbarium and museum buildings which were erected during that year. The director undertook no less than thirteen botanical explorations during the year, including one of Mount Kosciusco. The botanical results of these expeditions have been published in the *Agricultural Gazette of New South Wales* or elsewhere.

THE importance of variations in the osmotic pressure to the phenomena of vegetable life is illustrated in a reprint from the *Botanical Gazette*, by Mr. B. E. Livingston, entitled "On the nature of the stimulus which causes the change in form in polymorphic green Algæ." A series of experiments on a species of Stigeoclonium led him to the conclusion that these changes in form were due to variations in the concentration of the nutritive medium (Knop's solution), and not in any way to changes in its chemical composition.

AN important contribution to our knowledge of the flora of North America is issued by the U.S. Department of Agriculture (division of botany), as vol. vii. No. 1 of *Contributions from the U.S. National Herbarium*. It consists of a monograph of the North American Umbelliferæ by Profs. John M. Coulter and J. N. Rose. It enumerates and describes 62 native genera and 332 native species, besides introduced genera and species, the highest previous publication having been 52 native genera and 217 native species. The monograph is illustrated by a number of excellent wood-cuts representing either the general habit or the characteristics of the fruit of the species.

A BILATERAL division in the parietal bones of monkeys, according to a paper by Dr. Aleš Hrdlička in the *Bulletin* of the American Museum for December 31, seems to be a rare feature.

THE October issue of the *Bulletin* of the New Mexico College of Agriculture and Mechanic Arts is devoted to a series of observations and notes on the injurious insects of the country, by Prof. T. D. A. Cockerell.

DR. W. F. PURCELL contributes an important paper on the anatomy of *Opisthopatus cinetipes* to the *Annals* of the South African Museum (vol. ii. part 4). This arthropod, we may remind our readers, is a near ally of the more familiar Peripatus. The author is of opinion that the members of the group met with in Africa may be classified as follows:—(1) Peripatopsis, South Africa; (2) Opisthopatus, South Africa; (3) Peripatus, America, Africa, and possibly India. The distribution of the last-named, in connection with prevalent ideas as to the relationship of the South American and African faunas, is significant.

MR. J. D. E. HOLMES, superintendent of the Civil Veterinary Department, calls attention, in *Bulletin* No. 42 of the Department of Agriculture, Madras, to native beliefs connected with "hair-marks" on horses and cattle. These hair-marks, it appears, are formed by the changes in the direction of the hair on certain parts of the body, and, according to their shape, are denominated a crown, ridge, or feather-mark. Throughout India, but more especially in Madras, the value of a horse or an ox in native estimation depends almost entirely on the presence and situation of

certain of these hair-marks. According to native ideas, the old maxim that "a good horse cannot be a bad colour" does not hold good, white, dun, grey, piebald and skewbald animals being much more highly esteemed than those of other colours. A white bullock, again, is held to be of little value, while a black one is regarded as vicious.

SEVERAL popular scientific articles appear in the February number of *Pearson's Magazine*. Mr. R. S. Baker gives a description of some of Sir John Murray's work in oceanography, this being the first of a series on the science of the sea. Mr. Alder Anderson describes Russian Imperial forestry; Mr. T. E. James writes about the remarkable Crater Lake, Oregon; and Mr. T. Morton corrects some mistakes about rainbows in pictures, illustrating his contribution with several good photographs of rainbows. In *Good Words*, Miss G. Bacon describes the Yerkes Observatory; and there are also articles on an ascent of Mount Rainier—the highest mountain in the United States outside Alaska—the effect of light of various wave-lengths upon the growth of plants, the Purbeck marbles, and Miss Mary Kingsley.

IN an address recently delivered to the Chemical Society of the Goldsmiths' Institute, Dr. Julius Lewkowitsch dealt with "The Profession of an Industrial Chemist." The views of Dr. Lewkowitsch, who has had a long experience of manufacturing chemistry both in Germany and in this country, are entitled to very careful attention. He is able to recall the days when in Germany the chemical manufacturer was chiefly a merchant who thought he was marching with the times when he took into his works a young man to act as a testing machine and to become, later on, when he had shaken off the last remnants of chemical knowledge, assistant works manager. Dr. Lewkowitsch points out how entirely this condition of things, which is still prevalent in England, has changed in Germany. His main contention is that that the training which is most effective is that which is most liberal and educationally thorough. He has no grudge against the classics; on the contrary he extols their educational value when properly taught, and he is more solicitous that the school teaching of science should develop the logical faculty than that it should impart a fund of specialised knowledge. In the University period he would have a broad, thorough and unbiased study of chemistry and allied sciences ending, where possible, with some training in the special methods of technological laboratories. He concludes with a very graphic and complete account of the circumstances with which the chemist, so far trained, will have to contend in the works and the conditions necessary for his becoming the scientific master of his surroundings. Dr. Lewkowitsch's address combines high educational ideals with keen appreciation of practical requirements, and it deserves a wide circulation among those who are concerned directly or indirectly with chemical industries.

THE additions to the Zoological Society's Gardens during the past week include a Red-faced Ouakari (*Ouacaria rubicunda*) from the Upper Amazons, presented by Mr. Alfred Hutchinson; a Long-eared Bat (*Plecotus auritus*), a Common Bat (*Vesperugo pipistrellus*), British, presented by Mr. Louis Grundel; a Feline Dourocouli (*Nyctipithecus vociferans*) from South Brazil, a Yellowish Capuchin (*Cebus flavescens*) from South America, two Sharp-tailed Conures (*Conurus acuticauda*) from Paraguay, a Common Waxbill (*Estrelda cinerea*) from West Africa, seventeen Blue-tongued Lizards (*Tiliqua scincoides*) from Australia, deposited; a Sœmmerring's Pheasant (*Phasianus soemmerringi*) from Japan, an Elliot's Pheasant (*Phasianus ellioti*), two Amherst Pheasants (*Thaumalea amherstiae*) from China, a Black-backed Kaleege (*Euplocamus melanotus*) from Sikkim, purchased.

OUR ASTRONOMICAL COLUMN.

VARIABILITY OF EROS.—A circular from the Centralstelle at Kiel calls attention to an important notice from Dr. E. von Oppolzer respecting the planet Eros. He says that Eros shows a variation of brightness of about one magnitude, the change taking place in a few fours. It is in the highest degree desirable that, so far as possible, numerous estimations with neighbouring stars should be made in the course of each night.

CATALOGUE OF PRINCIPAL STARS IN COMA BERENICES CLUSTER.—The sixteenth issue of *Contributions from the Observatory of Columbia University*, New York, contains the discussion and reductions by Mr. W. C. Kretz of a series of measures of this cluster, from photographs obtained by Dr. Rutherford with his 13-inch refractor during 1870–76. The eleven standard stars adopted were reduced from the records of thirty-five catalogues, extending from that of Bradley in 1755 to the Greenwich results, 1887–94. The method of reduction is given in detail with tables of data for determining final positions, concluding with a list of twenty-four stars showing corrected coordinates and proper motions.

UNITED STATES NAVAL OBSERVATORY.—The report of the superintendent of the Naval Observatory at Washington deals with the progress of work during the fiscal year ending June 30, 1900. All the instruments have been in use on every clear night and day.

The 26-inch equatorial has been devoted to observations of difficult double stars, satellites of planets, and a long series of investigations on the use of ocular colour screens for planetary and double star measurements. The double floor, mentioned in a previous report, has undoubtedly improved the working conditions in partly eliminating the variable air currents in the dome. Certain markings have been observed on the disc of Neptune indicating a similarity to the belts of Jupiter.

Photographs of the sun have been taken with the photoheliograph of 40-feet focal length on every fine day, except in April and May, when it was dismounted for use during the total eclipse of the sun. For this eclipse an extensive programme, including spectroscopic, polariscopic and other items, was successfully carried out, the report of which will be ready shortly.

DOUBLE STAR MEASURES.—In the *Astronomische Nachrichten* (Bd. 154, Nos. 3680–1), Dr. Doberck gives a long series of measures of double stars obtained with the 14-inch refractor of the University Observatory, Copenhagen. Comparisons are discussed between the performance of short and long focus instruments with respect to the measurement of close doubles.

SCIENCE AT SHEFFIELD UNIVERSITY COLLEGE.

TWO addresses delivered at the University College of Sheffield on Thursday last, the occasion being the annual distribution of medals, prizes and certificates to successful students of the Technical Department, should be of service to science and technical education in the city. One was by Dr. H. C. Sorby, F.R.S., who during the greater part of the past fifty years has been occupied with scientific research. His remarks on the practical value of scientific theory admit of wide application, and the following report from the *Sheffield and Rotherham Independent* will be read with interest. A valuable address on technical and scientific education was also given by Alderman W. E. Clegg, who in the course of his remarks indicated three directions in which future efforts should be devoted in order to maintain our position in the industrial world; they are:—

(1) Greater energy and enterprise on the part of our manufacturers in utilising to the utmost existing markets, finding fresh ones, seizing every opportunity which presents itself to develop our increasing output and a greater adaptability and suitability of our goods to the requirements of our customers. (2) A closer union and real sympathy between employers and employed, each realising that the interests of the one are bound up in the interests of the other. (3) Greater interest and appreciation of the advantages of a technical and scientific education, and in connection with this all possible facilities should be given to men and boys to enable them to learn the science—the why and wherefore of the particular work they are engaged in—so that they can take an intelligent interest in what they are doing and what they have to do.

Dr. Sorby spoke as follows :—

What he proposed that evening was to say something with regard to the interdependence of the different branches of knowledge. He would speak only of physical science, and he would confine his remarks to what bore directly on the Technical School. He was very sorry to say that as things were at present many looked upon the University College as quite a distinct thing from the Technical School. Unfortunately there were two buildings, and he thought that had something to do with the idea. But he did hope that before long there would not be two buildings. He hoped they would succeed in erecting a University College that would include all the branches, and he would very much like to see written over the door: "Scientia una et indivisa."

He took it that he might assume that knowledge such as they were trying to teach in the University College might be divided into two divisions—what they might be pleased to call science, theoretical and practical. Now he maintained that the division between theory and practice was perfectly evanescent. It might be convenient to divide them, as it was convenient to divide yesterday and to-morrow; but when to-morrow came, to-morrow would not be to-morrow. It was the same with theory and practice in science. What was looked upon to-day as abstract theory, and of no practical use, would probably be to-morrow the foundation of some most important practical question which would revolutionise the whole world. He could not call it a feud, but the division of these two branches—theory and practice —was now non-existent. He was afraid that a good many people looked upon some branches of the subjects which were studied in the college as of not very much use, simply because they did not enable them to make puddings or construct anything else. He maintained that that was a very false view of the matter. Now, he had often heard in years gone by that theory was no good! What was wanted was good practical knowledge. In illustrating that idea, he would refer to a matter he recollected when we were carrying on the war in the Crimea. It was said that when the Russians built Sebastopol they furnished the labourers with wheelbarrows. The men had never seen a wheelbarrow before, and they filled them with earth and carried them on their backs. They could very well imagine some accomplished Russian officers pointing out the advantage of the wheelbarrow, and telling them how much labour might be saved by pushing the barrows instead of carrying them. Some of those labourers might have replied that they did not care a bit for what the officer said; what they really wanted was a good practical knowledge of how to carry the wheelbarrow on their backs. It was not so many years ago that one heard similar remarks to this in reference to a great many other subjects than wheelbarrows. He thought he might even say that in some cases pure theory was much more practical than practice.

There were cases where they could obtain a result with ease and accuracy by calculation, and if they attempted to do it by practice they would not do it so easily, and they would not do it with anything like accuracy. In such a case he held that theory, after all, was the much more practical of the two. He had been talking to Dr. Hicks about a subject for a lecture which he hoped to give from that desk in time to come, and he suggested as the title of that lecture, "The value of knowledge thought to be useless." There were no end of interesting illustrations to be found, and he was sure it would be a very good subject for a popular lecture. He could not help slightly trenching on that lecture because it had a lot to do with what he was trying to point out that evening. Some 2500 or 3000 years ago it was found that if you rubbed amber on cloth or anything of a similar nature it would attract little bits of paper. The Greek word for amber was "Electron." What would anybody have thought in those days if any one had said that if you only studied that peculiarity a little more you would be able to have tramcars with halfpenny fares? He need not describe what would have been the opinion of people in those days on that subject. Then again, the lodestone was called by a word which ultimately led to the word "magnetism." It was known that lodestone would attract bits of iron, and he believed it was Pliny who said that it had "such a great love for iron that it pulled pieces of iron to it." No doubt that idea and very little more than that notion existed for something like 1500 years. Then somebody found out that you could magnetise a needle, and that it would point to the north, and shipping was entirely revolutionised. Then again, Galvani, fortunately, was taken ill, and it was thought it would be a very good thing for him to have some frogs for dinner. When the cook placed the frogs' legs on the pewter plate on which they were served she noticed that they began to kick. She thought this very curious and drew Galvani's attention to it. The result was the discovery of Galvanism. These things were known for a very long time. He remembered the time before the principle of electro-plating was discovered. He recalled the man who discovered how to electro-plate with silver. They used to entertain themselves with making galvanic batteries and trying experiments. He remembered very well that his friend said, "Well, now, Sorby, I don't see any reason why we should not study these things, although people say that electricity is a thing that can never be of any use to anybody." What would anybody say if that remark were made to-day?

About thirty-six years ago he pointed out how very important was the investigation of the microscopical study of iron and steel. He read a paper at the British Association meeting at Bath, and his specimens were exhibited before the Royal Society. They were very much admired, and thought very pretty, but for twenty-three years nobody did anything; nobody took the slightest interest in the subject. Eventually the Iron and Steel Institute asked him to read a paper on the subject. He did so, and the result was that the study of the microscopic structure of iron and steel was now thought of great importance. One felt very pleased to think that things had moved so, because this microscopic investigation, which was so long dormant, was now employed in almost every civilised country, and he was very proud to think that the Sheffield Technical School was at the front so far as this subject was concerned. Prof. Arnold, whom he very greatly regretted was ill, was selected by the Admiralty to make an investigation into the structure of the steel shaft which failed on one of H.M.'s torpedo boats. Prof. Andrews was also an authority on the structure of steel rails, and he was often consulted in connection with railway accidents. He did not want to occupy too much time, but what he did wish to impress on his audience was this, that judging by the experience of years gone by there was nothing that you could discover that might not turn out to be of the greatest possible value. You could not say that it would, but you could not say that it would not. As an example, some few years ago a friend of his was examining under the microscope with a very high power the blood discs in the blood of frogs, and he discovered in these blood discs certain curious little things which were found to be very minute parasitic animals. If they had mentioned this to the man in the street he would have thought that it was a most absurd idea to pay much attention to a thing like that. But a further study of that subject had led to the knowledge of the real cause of a disease which in India killed annually about as many people as the whole of the population of England, and not only had they learned the cause of the disease, but there was every probability that they would succeed in putting a stop to it. The magnitude of the result was almost incomputable.

He could liken them all to a small colony on a big continent. They made a few roads and settled down. But if they were content with these few roads and never troubled themselves about the backland, how would they progress? Some other country would take the backland. What they wanted was to explore the unknown; to march to the top of some mountain and look down on the country never seen before by civilised eyes. They would then find valuable gold mines, coal, and all manner of things. If they were content with what they knew they would make no progress. They might hold their own, but he did not know whether they would do that. They should try to learn fresh things. His friend, Alderman Clegg, was about to distribute the prizes, which were all very well in their way, but he should like to see them win prizes for original research, to make discoveries and invent new industries, and conquer the trade of the world. They ought to develop the manufactures in this city in such a way that they might beat the Germans and the Americans, so that they might capture the trade of the whole world in their particular department. This electric railway in London—the only thing that was English about it was the tunnel. The only thing about that railway that was made in England was the tunnel. Everything else was American. It has even been said that it was surprising that the tunnel had not been sent to America to be made. But they did not want that sort of thing to go on, and in order to prevent it they must have no rivalry between theory and practice in science. He hoped they would be able on another occasion to meet in a building worthy of the town, and where all these different subjects would be correlated and united in one.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—The degree of D.Sc. *honoris causa* has been conferred upon Dr. Oliver Lodge, and the degree of D.Litt. *honoris causa* upon Dr. F. J. Furnivall.

Mr. A. E. Boycott, of Oriel, has been elected to a senior demyship at Magdalen College to enable him to continue research in physiology and pathology.

CAMBRIDGE.—The collection of ethnological specimens formed in the Maldive Islands by Mr. J. Stanley Gardiner has been gratefully accepted by the University for the Museum of Ethnology.

Dr. A. W. Ward has been elected a member of the council of the Senate in the place of Bishop Ryle.

The following have been appointed electors to professorships:—Chemistry, Dr. A. Macalister; Plumian (astronomy), Dr. Ferrers; Anatomy, Prof. Newton; Botany, Prof. Bayley Balfour; Geology, Dr. R. D. Roberts; Jacksonian (natural philosophy), Dr. J. Larmor; Downing (medicine), Prof. Liveing; Mineralogy, Mr. J. E. Marr; Zoology, Mr. F. Darwin; Mechanism, Prof. Forsyth; Physiology, Dr. P. H. Pye-Smith; Surgery, Dr. D. MacAlister; Pathology, Prof. Allbutt; Agriculture, Dr. D. MacAlister.

Mt. Clinton T. Dent has been appointed an examiner in surgery in the place of Prof. Chiene.

The Isaac Newton Studentship in physical astronomy has been awarded to Mr. S. B. McLaren, of Trinity, third wrangler 1900.

The Adams Prize, for a memoir on electric waves, has been awarded to Mr. H. M. Macdonald, Fellow of Clare.

A Shuttleworth Scholarship in botany and comparative anatomy, of the value of 55*l*. a year for three years, will be filled up at Caius College in March. Candidates must be medical students of not less than eight terms' standing. Application is to be made to the senior tutor by March 1.

MR. E. J. GARWOOD has been appointed to the Yates Goldsmid chair of geology and mineralogy at University College, London, in succession to Prof. T. G. Bonney.

PROF H. LLOYD SNAPE has been appointed Director of Education to the Lancashire County Council. Formerly the directorship was limited to technical instruction, but the duties of the office have now been enlarged by the inclusion of all education other than elementary. For more than twelve years Dr. Snape has held the chair of chemistry at the University College of Aberystwith.

THE Manufacturers' Association of New York recently voted the sum of 2000 dollars for an industrial scholarship, including the cost of tuition for four years and incidental expenses. The purpose of the association in providing means for the industrial education of a young man of Greater New York is to encourage young men to qualify themselves for leadership in industrial pursuits. A committee has been appointed to arrange the details and to conduct the examination of the candidates.

A PAPER on the national organisation of agricultural education, contributed to the January number of the *Record* of Technical and Secondary Education, directs attention to the need for establishing instruction in agriculture upon a foundation of general science instead of regarding it as a special science with its own particular principles. Other articles in the *Record* deal with the organisation of individual secondary schools, local schemes of commercial education, education at the Paris Exhibition, horticultural education in Surrey, and school gardens.

THE following is a single week's statement of gifts to educational and scientific institutions in the United States. The announcements are from *Science*. John D. Archbold, of New York City, a vice-president of the Standard Oil Company, has given 400,000 dollars to the endowment fund of Syracuse University, on the condition that a like amount be raised among other friends of the institution; Mr. Andrew Carnegie has given 225,000 dollars to the Upper Iowa University, at Fayette, Ia., to be used preferably for a library, and 50,000 dollars to Aurora College, an Illinois institution; Augustana College at Rock Island, Ill., has received about 30,000 dollars from Messrs. E. C. and J. A. Ericsson, of Boone, Ia.; Mr. John D. Rockefeller has offered to give 15,000 dollars to Carson and Newman College, a Baptist institution in Tennessee, provided 50,000 dollars in addition be raised; Carleton College, at Northfield, Minn., has added 150,000 dollars to its permanent endowment fund, 50,000 dollars being the gift of Dr. D. K. Pearsons, and the remaining 100,000 dollars being raised from various sources.

A RETURN just issued by the Board of Education brings together a large amount of information as to the award of scholarships by County Councils in England. The scholarships are divided into three classes, viz. (1) junior scholarships intended to enable pupils in elementary schools to proceed to secondary schools; (2) intermediate scholarships, usually in continuation of junior scholarships, and tenable at secondary schools or technical colleges; (3) major or senior scholarships, comprising also those awarded in various special subjects. It appears from the Return that of the 4678 winners of junior scholarships specified, 4231 were in attendance at an elementary school, and 447 at a secondary or other school. Of the 519 winners of intermediate scholarships, 307 had previously held junior scholarships. The number of major scholarships awarded by the County Councils for general proficiency is 360, in addition to which 188 are awarded for agricultural subjects, 43 for horticultural subjects, and 150 for mining. These scholarships vary considerably in value, but generally they are of larger amount than those of the other classes, and some of them enable students to proceed to institutions of University rank. Particulars are given in the Return of all the County Council scholarships awarded in England in the three financial years ending on March 31, 1899, and also of the occupations of the parents of the winners of the scholarships. We see from this that the children of "professional and general" parents head the list of scholarship winners, and are followed by those of "clerks, agents and warehousemen," and then by children whose parents follow "building trades." It is evident, however, that the relative abilities of the children of parents of the different classes cannot be estimated from the positions of the children in the list without knowing the proportional numbers of each class in the population.

THOUGH there are few signs that the scheme for the establishment of a West of England University is making much headway, the speech by Sir Michael Foster at a meeting held at University College, Bristol, last week, and attended by many men of influence and means, should do something to bring about a *modus operandi* between the authorities of the educational institutions which would form part of the University. Sir Michael Foster remarked in the course of his speech:—"One idea in the establishment of Universities in the renaissance was that each University was a guild for the advancement of learning, and that had, with various changes, remained their object ever since. They were institutions for the advancement of learning; not only for the spreading of knowledge, but for the pushing forward of the known into the unknown. They had been through all time, with little variation, the great instruments of inquiry and research. A teaching body, whether it was called a college or a University, was a University in principle and in reality, and the whole of its actions were governed by the dominant principle of research, of inquiry into the unknown. Universities, to be real and true Universities, ought not to be merely machines for converting knowledge into pap and distributing it into open mouths. They ought to have some living feature and act as ferment upon the young minds, inducing changes, so that knowledge would grow up of itself in the mind when the mind was brought under its influence. It was this vital and living feature which was the dominant feature of a University, or a University College, or of the teaching of any University, by whatever name it was called. He would say to the citizens of Bristol that they had in their midst a body—whether they called it a University or a University College it was practically a University—the teachers of which he knew from personal knowledge to be truly inspired with the feeling of the necessity of inquiry into the unknown. He ventured to suggest that it was desirable such an institution, which must have great influence on all the intellectual progress, and therefore on the material advance of the West of England, ought to be founded, not upon the shifting sands of annual subscription, but upon the solid rock of permanent endowments." The citizens of Bristol should learn from this that they have in University College a nucleus of a modern University like that founded in Birmingham upon Mason College. Nothing should be permitted to delay the formation of an organic plan, to realise which an appeal for endowments can be made. The West of England ought to show that it can nurture education and science as well as the Midlands.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, February 7.—"On the Proteid Reaction of Adamkiewicz, with Contributions to the Chemistry of Glyoxylic Acid." By F. Gowland Hopkins, M.A., M.B., University Lecturer in Chemical Physiology, and Sydney W. Cole, B.A., Trinity College. (From the Physiological Laboratories, Cambridge.) Communicated by Dr. Langley, F.R.S.

The proteid reaction described by Adamkiewicz is not a furfurol reaction, but depends upon the presence of small quantities of an impurity in the acetic acid employed. Some specimens of acetic acid yield no reaction, and all may be deprived of chromogenic power by distillation.

The substance essential to the reaction is glyoxylic acid.

Small quantities of glyoxylic acid are produced during the oxidation of acetic acid by hydrogen peroxide in the presence of ferrous iron. Under the conditions used in this research, part of the glyoxylic acid thus formed is split up, yielding formaldehyde.

Glyoxylic acid is slowly formed when acetic acid stands in the air, and more rapidly in the presence of ferrous iron and under the influence of direct sunlight. Most specimens of acetic acid contain small amounts of glyoxylic acid as an admixture.

A dilute aqueous solution of glyoxylic acid, which may be readily prepared by the reduction of oxalic acid with sodium amalgam, forms an admirable test for proteids when used instead of acetic acid under the ordinary conditions of the Adamkiewicz test.

"Further Investigations on the Abnormal Outgrowths or Intumescences in *Hibiscus vitifolius*, Linn.: a Study in Experimental Plant Pathology." By Elizabeth Dale. Communicated by Prof. H. Marshall Ward, F.R.S.

The conclusions drawn from the experiments are that the outgrowths are formed in a moist atmosphere, provided that there is also adequate light and heat.

The immediate effect of the damp atmosphere is to check transpiration. This, in its turn, by blocking the tissues with water, disturbs the normal course of metabolism, and so leads (when the light and heat are sufficient) to changes in the metabolic activity of the plant, as is shown by the following facts:—

(1) The outgrowths only develop if transpiration is reduced.

(2) The outgrowths are chiefly formed on organs which are actively assimilating, *e.g.* under ordinary red or yellow glass; but only if transpiratory activity is lowered: they are not formed in the open.

(3) They only occur (*ceteris paribus*) in plants in which there is an accumulation of starch.

(4) They are formed under clear glass and under red and yellow glass, but not under blue or green glass, and in no case in darkness.

(5) Their formation is accompanied by the production of oil, which is not found in normal leaves.

(6) The presence of this oil suggests that events similar to those occurring in succulent plants are taking place, viz., reduced respiration and the development of osmotically active substances in excess.

(7) It is therefore probable that the intumescences are due to the local accumulation of osmotically active substances, produced under the abnormal conditions, viz., reduced transpiration and consequent lack of minerals, while carbohydrates are being developed in excess.

Physical Society, February 8.—Annual General Meeting. Mr. G. Griffith, Vice-president, in the chair. The report of the council was read and adopted. Prof. Willard Gibbs and Dr. Rudolph Koenig were elected to the two vacant honorary fellowships of the Society. The following officers and council were elected for the ensuing year:—President: Prof. S. P. Thompson. Vice-presidents (members who have filled the office of president): T. H. Blakesley, C. V. Boys, Prof. J. D. Everett and J. Walker. Secretaries: H. M. Elder and W. Watson. Foreign Secretary: Dr. R. T. Glazebrook. Treasurer: Prof. H. L. Callendar. Librarian: W. Watson. Other members of the Council: Prof. Armstrong, W. R. Cooper, G. Griffith, E. H. Griffiths, Dr. R. A. Lehfeldt, S. Lupton, Prof. Perry, Dr. Porter, W. A. Price and R. Threlfall.—Prof. S. P. Thompson then took the chair and delivered an address. In opening, the President gave in detail the various ways in which the aim of the Physical Society to promote the progress and study of physics has been accomplished during the twenty-six years of the Society's existence. Referring to the election of two honorary fellows, Prof. Thompson said they had added to their roll two men distinguished in very different walks of physics. Prof. Willard Gibbs is a United States mathematical physicist whose work in thermodynamics, elastic solid theory of light and other specialised subjects is of the highest order and is valued for its beauty and profundity. Dr. Rudolph Koenig, of Paris, is known as a maker of acoustical instruments—of perfect standard, tuning-forks in particular. He has, however, found time to extend the borders of acoustics, and to him we owe the manometric flames, the wave syren and other instruments of research. He has also published work on the facts about the combinations of pure tones. The President appealed to all teachers of physics in the country to make use of the Society and give it their active support. It was mainly in the interest of teachers and students that the Society undertook the publication of science abstracts. By means of the abstracts teachers have at hand the latest information on the subject, and can thus continually supplement their text-book knowledge. Every teacher, from time to time, devises new or improved modes of presenting his subject. At the Physical Society the Fellows always welcome contributions of this kind, even though there may be little of actual novelty in the principles so illustrated. The routine work and administrative duties of teachers, although hampering their usefulness to science and diminishing their fruitfulness, prevent their attention, without intermission, to one subject and produce a direction of thought over varions domains of physics which is to be welcomed rather than deplored. It has been the custom for Fellows of the Physical Society to bring models to illustrate physical principles. This practice of using models is regarded by our Continental brethren as a peculiarly English matter and one that shows a sort of mental constitution they do not quite understand. Models have become a part of our mental furniture. It never occurs to us that there is anything unusual in the habit. Faraday has used them in connection with the electrostatic field surrounding charged bodies. Lord Kelvin has made models to convey his ideas of elasticity, of the elastic solid theory of matter and of the constitution of matter itself. Maxwell's models of heterogeneous dielectrics and the mutual induction between two circuits are well known. These models are useful for teaching purposes and for enabling one to grasp that which in its nature is abstract by contemplating the representation of it or its analogue in the concrete. The French physicist cannot understand a complicated phenomenon until he has reduced it to a mathematical equation. The British physicist must construct a model which will produce mechanically the analogous operation. Both methods are right, but judging by their fruitfulness the method of Faraday has advantages over that of Poisson. Referring to the New Teaching University of London, the President said that now was the time for Fellows to offer suggestions for the teaching of physics.—An ordinary meeting of the Society was then held.—A paper on a mica echelon grating, by Prof. R. W. Wood, was read by Mr. Watson. This grating occupies a position midway between an ordinary grating and an echelon with thick plates. A number of sheets of mica were examined with the interferometer and one selected, over a considerable portion of which the fringes were straight and unbroken. This portion was marked off and cut up into rectangles. The mica was about 0·05 mm. thick, and the retardation of one of the rectangles was found to be fifty wave-lengths for sodium light. Nine of these rectangles were used to form the grating, and they were put in position under a microscope and cemented together at the edges with sealing wax. The grating space was 0·5 mm. The battery was mounted on a square of cardboard over a rectangular opening of the same size, a clear space 0·5 mm. wide being left to serve as the first grating line of zero retardation. The number of lines was therefore ten. The resolution of the sodium lines was beyond the power of the instrument, but the yellow mercury lines were easily separated. The distance between the lines was one-third of the distance between the spectra. For the sake of comparison, a grating of the same spacing and number of lines was ruled on a piece of smoked glass, and it was found that in the first order the grating was unable to separate the extreme red and blue ends of the spectrum. The Zeeman effect can be shown with an echelon made of four interferometer plates, the light being the green rays from a mercury tube. The Society then adjourned until February 22.

EDINBURGH.

Royal Society, January 21.—Lord Kelvin, President, in the chair.—The Chairman communicated a paper on one-dimensional illustrations of the kinetic theory of gases, in the course of which he referred to Waterston's doctrine of the partition of energy among molecules of different size, a doctrine which, although supported by Maxwell, Boltzmann and others, he believed to be not only not proved but not true. If the doctrine is found to fail in one particular case, its universality is disproved. By considering the impacts among a row of hard elastic spheres constrained to move to and fro in the same straight line, he had, by direct calculation of the effects of 300 successive collisions, found no tendency towards a state in which the average energy of *all* the masses was the same. When the time of impact was assumed to be infinitely short, so that no more than two spheres could be in contact at the same time, the calculation was simple enough; but the problem quite changed its character when the time of impact was taken as finite, so that three or more particles might be in contact at the same time. It was shown that impenetrability was not a necessary quality of molecules. If we follow Boscovich and regard them as centres of force, then two molecules might, on collision, simply pass through one another.—Dr. Knott read the first part of a paper on solar radiation and earth temperatures, in which a comparison was made between two sets of data, the one derived from Langley's well-known results, the other from a recent discussion by Dr. Buchan of temperature observations made at various depths in the eastern part of the Mediterranean Sea by the Austrian ship *Pola*. These seemed to indicate a daily see-saw of temperature in a stratum of surface water 50 metres thick. It was difficult to credit direct solar radiation with the power to penetrate so deep; but the difficulty was greatly increased when a simple calculation showed that the afternoon excess of temperature which was indicated meant an accumulation of 1460 units of heat under each square centimetre of surface during eight hours of daily sunshine. For, with Langley's value of the solar constant, it could be calculated that the *whole solar energy supplied* to each square centimetre of the earth's surface in the latitude of the Mediterranean during eight hours of the midsummer day did not exceed 750 units. This serious discrepancy seemed impossible of explanation if the general accuracy of both sets of data was assumed.—Dr. Thomas Muir communicated three papers, namely, note on pairs of consecutive integers, the sum of whose squares is an integral square; the differentiation of a continuant; and the Hessian of a general determinant. By direct calculation of the various elements, it was shown that the Hessian of the determinant D of the nth order had the value $\pm(n-1)D^{n(n-2)}$.

PARIS.

Academy of Sciences, February 4.—M. Fouqué in the chair.—Notice on M. Agardh, by M. Bornet.—On the origins of chemical combination. The allotropic states of silver, by M. Berthelot. The method employed is to measure the amount of heat developed by the various allotropic modifications of silver when dissolved in mercury. The five kinds of silver employed gave for 108 grams of the metal amounts of heat varying between 0·08 calorie and 2·03 calories. The values previously obtained for the heats of combination of silver with other elements depend, therefore, upon the state of the metal used, and hence require a correction.—Studies on the combinations of silver with mercury, by M. Berthelot.—On the isentropic stability of a fluid, by M. P. Duhem.—A simple apparatus for the application of the phototherapic method of Finsen, by MM. Lortet and Genoud. The rays from an arc lamp are concentrated by means of a globular flask, through which cold water is kept running. The greater part of the heat is absorbed by the water in the lens, and the apparatus has given good results in actual clinical practice.—Remark on the subject of a note by M. S. Kantor, by M. F. Enriques.—On pencils which are transformed on two sides into orthogonal pencils by the method of Laplace, by M. C. Guichard.—On the density of the zeros and the maximum modulus of a complete function, by M. Pierre Boutroux.—On the relation between the solar activity and the diurnal variation of the magnetic declination, by M. Alfred Angot. This problem has been attacked by applying the method of Fourier to the observations of Paris and Greenwich, the values for the constants obtained in the two cases agreeing very well.—On the borates of magnesium and the metals of the alkaline earths, by M. L. Ouvrard. By heating to a dull red heat a mixture of magnesia, boric anhydride and potassium hydrogen fluoride, the borate $B_2O_3,3MgO$ is obtained in a well crystallised state. The corresponding compounds of barium, strontium and calcium were also isolated.—On the electrolysis of the oxy-acids. Preparation of β-amyloxypropionic acid and of the diamyline of butanediol, by M. l'abbe J. Hamonet. To prevent the occurrence of secondary reactions with the hydroxyl group, the hydrogen of this group was replaced by an alkyl group, and the potassium salt of this compound electrolysed. No satisfactory results were obtained with α-oxy-acids, but with β-oxy-acids the synthesis was smoothly effected in the required direction.—On the saccharifying action of wheat germs, and on their use in brewing, by M. Lindet. Owing to the extensive use of roller milling, the germ of the wheat is entirely separated from the farinaceous portion of the grain. A comparative study of the action of wheat germs and malt upon a solution of dextrinised starch showed that practically the same amount of sugar was produced in each case. In the case where the wheat germs are employed, the distillery residues will have a higher feeding value.—The legend of *Lepas anatifera*, and of *Vallisneria spiralis*, by M. Frédéric Houssay.—The *Ramy* of Madagascar, by M. H. Jacob de Cordemoy. The author identifies the *Ramy* of Madagascar with *Canarium multiflorum*. This tree exudes a greenish-yellow resin which is formed in the stem in resinous canals which are specially developed in the liberian tissue.—On a new genus of fossil stem, by M. B. Renault. The fragment of stem described was found in a dolmen of Haute-Alsace. It is named *Adelophyton julieri*.—On the presence of a layer of Devonian anthracite at Kouitcheou in China, by M. G. H. Monod. The fossils found in the coal-measures at Lan-mou-tchang, in Koui-tcheou, and in the neighbouring strata show that these are clearly Devonian. This field shows that the vertical extension of the coal in China is greater than had been supposed, and this extension ought to be still further increased.—The culture and reproduction of the salmon (*Salmo salar*) in fresh water, by M. Jousset de Bellesme. The experiments described prove that the culture and reproduction of the salmon is possible in fresh water exclusively. This gives rise to the belief that although the habit of going to the sea is favourable to its development, it is neither very ancient nor absolutely necessary to its reproduction.—On the constitution of the soil at great oceanic depths, by M. J. Thoulet. As a result of the study of sixty specimens taken at various depths by the Prince of Monaco, the views previously put forward by the author are confirmed.—On a small laboratory furnace, by M. Albery Bruno.

ST. LOUIS.

Academy of Science, December 17, 1900.—Dr. O. Widmann read an account of the great St. Louis crow-roost, in which were embodied many facts concerning the life-history and habits of the common crow.—Prof. F. E. Nipher gave an account of some of his recent results in positive photography. He has now found that hydrochinone baths of normal strength may be used. The formula given in each box of Cramer plates yields good results if the mixed bath is diluted with water to one-third strength. The potassium bromide may be left out, and one drop of concentrated hypo-solution must be added for each ounce of diluted bath. The hypo has a most wonderful effect. With the same bath, plates may be developed as positives in the dark room or in direct sunlight. He had even started the developing of a plate in a dark room, where it progressed very slowly, but very satisfactorily; continued the operation in diffused daylight in an adjoining room, and finished the operation in direct sunlight. The process was accelerated by the light, but did not appear to be otherwise changed by the change in illumination. The resulting picture could not be distinguished from those produced by ordinary methods. This picture was shown by means of the lantern. A box of Cramer's "Crown," "Banner" or "Isochromatic" plates may have the plates individually wrapped in black paper, in the dark room or at night, and all the remaining work may be done in the light. A plate is taken from its wrapping into the lighted room and placed in the slide holder. After exposure, it is taken out into the light and placed in the developing bath, and the picture is then developed in the light, and may be fixed in the light. Of course, during the changes the plate should be shielded from the light as much as possible, and the fixing bath may always be covered. But all of the operations may be carried on without any dark-room conveniences that may not be secured even in the open fields. When weak hydrochinone baths are used, the picture, when developed in strong lamp-light, or in sunlight, has at first a golden yellow colour. When left in the lighted bath for an hour

and a half, it slowly darkens to a nearly normal shade, as the details come out more sharply. If the exposure has been correctly made, there will be no trace of fog. With stronger baths the picture comes out in the normal time, and has the normal shade. If the pictures are too dense, the remedy is to reduce the strength of the sodium carbonate solution, or to increase the amount of hypo in the bath. Very fine results are obtained with the sodium carbonate solution at half the strength given in Cramer's formula. When the plate has been sufficiently exposed, a negative of the object can usually be seen upon the plate before development. With long exposure this image is very distinct. It fades out in the bath, and the plate becomes clear. The shadows appear strongly, but indistinctly at first, and of a pink colour, and the high-lights still appear white. The solution remains clear. Too much hypo will cause turbidity and a loss of detail. When the plate is exposed in a printing frame under either a negative or a positive, an exposure of half a minute to diffuse daylight is ample with an ordinary negative. The plate may be over-exposed by placing it for a long time in direct sunlight, and it will then appear on development somewhat like an over-exposed negative. This has not yet been tried with hypo in the bath. Prof. Nipher showed a preliminary diagram, in which exposure and illumination of the developing bath were taken as co-ordinates. The zero condition was represented by a line, and the conditions for producing direct and inverted pictures were represented by areas. He also exposed and developed, in a common bath, in the lighted audience room, negatives printed from negatives, and positives printed from positives. The possible value of radio-active substances acting upon the developing plate in place of, or in addition to, light, was referred to as a most promising field for study.

DIARY OF SOCIETIES.

THURSDAY, FEBRUARY 14.

ROYAL SOCIETY, at 4.30.—Some Additional Notes on the Orientation of Greek Temples, being the Result of a Journey to Greece and Sicily in April and May, 1900: F. C. Penrose, F.R.S.—The Transmission of the *Trypanosoma Evansi* by Horse Flies, and other Experiments pointing to the Probable Identity of Surra of India and Nagana or Tsetse Fly Disease of Africa: Dr. Leonard Rogers.—On the Influence of Ozone on the Vitality of some Pathogenic and other Bacteria: Dr. A. Ransome, F.R.S., and A. G. R. Foulerton.—On the Functions of the Bile as a Solvent: B. Moore and W. H. Parker.——To be read *in title only*: On the Application of the Kinetic Theory of Gases to the Electric, Magnetic and Optical Properties of Diatomic Gases: G. W. Walker.—Heredity, Differentiation, and other Conceptions of Biology: a Consideration of Prof. Karl Pearson's paper "On the Principle of Homotyposis": W. Bateson, F.R.S.

MATHEMATICAL SOCIETY, at 5.30.—The Distribution of Velocity and the Equations of the Stream Lines, due to the Motion of an Ellipsoid in Fluid Frictionless and Viscous: T. Stuart.—On Factorisable Twin Binomials: Lieut.-Colonel Cunningham, R.E.—Concerning the Abelian and Related Linear Groups: Prof. L. E. Dickson.—A Geometrical Theory of Differential Equations of the First and Second Orders: R. W. Hudson.—Brocardal Properties of some Associated Triangles: R. Tucker.—A Note on Stability, with a Hydrodynamical Application: T. J. I'a. Bromwich.

SOCIETY OF ARTS (Indian Section), at 4.30.—The Greek Retreat from India: Colonel Sir Thomas H. Holdich, K.C.I.E.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Capacity in Alternate Current Working: W. M. Mordey. (Adjourned Discussion.)

FRIDAY, FEBRUARY 15.

ROYAL INSTITUTION, at 9.—Electric Waves: Right Rev. Monsignor Gerald Molloy.

GEOLOGICAL SOCIETY, at 3.—Annual General Meeting.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—Light Lathes and Screw Machines: J. Ashford.

EPIDEMIOLOGICAL SOCIETY, at 8.30.—The Epidemiological Aspects of Isolation Hospitals: Dr. Arthur Newsholme.

MONDAY, FEBRUARY 18.

ROYAL INSTITUTION, at 3.—Origin of Vertebrate Animals: Dr. Arthur Willey.

SOCIETY OF ARTS, at 8.—The Bearings of Geometry on the Chemistry of Fermentation: W. J. Pope.

SOCIETY OF CHEMICAL INDUSTRY, at 8.—Discussion on the Occurrence and Detection of Arsenic in Manufactured Products.

VICTORIA INSTITUTE, at 4.30.—The Wahabies: S. M. Zwemer.

TUESDAY, FEBRUARY 19.

ROYAL INSTITUTION, at 3.—Practical Mechanics: Prof. J. A. Ewing, F.R.S.

ZOOLOGICAL SOCIETY, at 8.30.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Nilgiri Mountain-Railway: W. J. Weightman.

ROYAL STATISTICAL SOCIETY (St. Martin's Town Hall, W.C.), at 5.30.—The Growth of Municipal and National Expenditure: The Right Hon. Lord Avebury, F.R.S.

ROYAL PHOTOGRAPHIC SOCIETY, at 8.—Imitative *versus* Creative—a Comparison: W. Edwin Tindall.

WEDNESDAY, FEBRUARY 20.

SOCIETY OF ARTS, at 8.—Some Features of Railway Travelling, Past and Present: Frederick McDermott.

GEOLOGICAL SOCIETY, at 8.—Submerged Valleys opposite the Mouth of the River Congo and of Western Europe: Prof. E. Hull, F.R.S.—The Geological Succession of the Beds below the Millstone Grit Series of Pendle Hill and their Equivalents in other Districts in England: Dr. Wheelton Hind and J. Allen Howe.

ROYAL METEOROLOGICAL SOCIETY, at 7.30.—Report on the Phenological Observations for 1900: E. Mawley.—A Review of Past Severe Winters in England, with Deductions therefrom: Albert E. Watson.

ROYAL MICROSCOPICAL SOCIETY, at 7.30.—Exhibition of Bacteria and Blood Parasites: C. Beck.

THURSDAY, FEBRUARY 21.

ROYAL SOCIETY, at 4.30.

LINNEAN SOCIETY, at 8.—On the Affinities of *Æluropus melanoleucus*, Alph. Milne-Edw.: Prof. E. Ray Lankester, F.R.S., and R. Lydekker, F.R.S.—Étude d'une espèce nouvelle de Lépapèdes: M. A. Gruvel.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—If the discussion on Mr. Mordey's paper is closed, the following paper will be read:—The Electrical Power Bill of 1900: Before and After: W. L. Madgen.

CHEMICAL SOCIETY, at 8.—(1) Isomeric Hydrindamine Mandelates and Phenylchloracethydrindamides; (2) Isomeric Benzylhydrindamine bromocamphorsulphonates and some Salts of *d-l*-Hydrindamine: F. Stanley Kipping and H. Hall.—Condensation of Phenols with Esters of the Acetylene Series. IV. Benzo-γ-pyrone and its Homologues: S. Ruhemann and H. W. Bausor.—Constitution of Bromocamphoric Anhydride and Camphanic Acid: A. Lapworth and W. H. Lenton.—The Action of Acetylchlor- and Acetylbrom-aminobenzenes on Amines and Phenyl hydrazine: F. D. Chattaway and K. J. P. Orton.

FRIDAY, FEBRUARY 22.

ROYAL INSTITUTION, at 9.—Metals as Fuel: Sir W. Roberts-Austen, F.R.S.

PHYSICAL SOCIETY, at 5.—How Air subjected to X-Rays loses its Discharging Property, and how it Discharges Electricity: Prof. Emilio Villari.—(1) On the Propagation of Cusped Waves and their Relation to the Primary and Secondary Focal Lines; (2) On Cyanine Prisms, and a New Method of Exhibiting Anomalous Dispersion: Prof. R. W. Wood.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Automatic Coupling: J. L. Cridlan.

SATURDAY, FEBRUARY 23.

ROYAL INSTITUTION, at 3.—Sound and Vibrations: Lord Rayleigh, F.R.S.

THE GENESIS OF ART.

The Origins of Art; a Psychological and Sociological Inquiry. By Yrjö Hirn. (London: Macmillan and Co., Ltd., 1900.) Price 10*s*. net.

THE various studies usually grouped under the general term of Anthropology are slowly but surely extending their scope. Not very long ago art was considered to be beyond the realm of science, and its exposition was mainly in the hands of art-critics; but of late years scientific methods have been employed to discover why works of art are created and why they are enjoyed, and to trace the modifications which they have undergone. Those who have paid attention to the subject have recognised, with Bastian, that art is a branch of psychology, and Herbert Spencer and Grosse have also laid stress on the immense importance of art in the evolution of human societies. It is therefore with great pleasure that we welcome an investigation into the origins of art from a psychological and sociological point of view by the learned Finnish savant, Dr. Yrjö Hirn.

Even a casual glance at this clearly and brightly written book will demonstrate that the author has assimilated a mass of information gained from a wide range of reading. A more careful perusal shows that he handles his facts judiciously, and keeps himself well in hand. The deductions are lucidly stated, and the authority for each statement of fact is quoted; the reader has, therefore, every facility for traversing an argument should it not appear at first sight to be valid.

To those who have a fair knowledge of the culture of primitive peoples the book will prove very suggestive, as new light will be thrown upon many well-known facts, and isolated observations will be brought into line.

In the following summary of the main arguments of the book the author's own words have been largely employed, which also will assist towards giving a more complete conception of the work. It is perfectly safe to prophesy that this book will prove of very great value not only to the student at home, but to the investigator in the field.

Despite the generally received dictum of "art for art's sake" it will often be found, especially among primitive folk, that some form of interest, personal, political, ethical or religious, enters into what is regarded as disinterested æsthetic activity. In almost every case where the ornaments of a tribe have been closely examined, it has appeared that what seems to us a mere embellishment is for the natives full of practical, non-æsthetic significance, such as religious symbols, owners' marks, or ideograms, and it is surprising what religious or magical significance lies concealed behind the most apparently trivial of amusements. The dances, poems, and even the formative arts of the lower races possess unquestionable æsthetic value; but this art has generally a utility, and is often even a necessity of life.

The play-theory of Groos, although it unquestionably is explanatory of a great deal, does not account for the origin of the artistic impulse. The aim of play is attained when the surplus vigour is discharged, or the instinct has had its momentary exercise; but the function of art is not confined to the art of production; something is made and something survives. Excitement and intense delight manifest themselves in movement, dances and songs which rather relieve incipient pain than express pleasure, violent movement acting rather as a regulator by which the organism restores itself to its natural state. By the control of the bodily movements, which form its simplest expression, joy may be diverted into the region of thought.

While supplying man with a means of intensifying all his varied feelings, art at the same time bestows upon him that inward calm in which all strong emotions find their relief. It is very difficult for an individual to resist the contagion of collective feeling, and all strong feelings act as socialising factors. A work of art is the most effective means by which the individual is enabled to convey to wider and wider circles of sympathisers an emotional state similar to that by which he is himself dominated.

Grosse and Wallaschek have emphasised the important part rhythm has played in the struggle for existence by facilitating co-operation, and the contagious power of an idea is vastly increased when it is cast in rhythmical form, whether it be the gymnastic dance, unmelodious music, poetry, or decorative art. Later, owing to more complex emotions, simple gymnastic dancing becomes pantomimic, and the drama is evolved. A histrionic element also manifests itself in other forms of artistic production—for example, literature and the formative and decorative arts of design. With the increased importance of the intellectual elements accompanying the emotional states, direct emotional suggestion appears an inadequate means of communication; and in ornament and music, as well as in painting and novels, there will be found an imitation of nature which serves what, in the widest use of the term, may be called an epic purpose.

In the endeavour to secure the transmission and perpetuation of a feeling, the expressional activity gradually loses its purely impulsive character and becomes transformed into deliberate artistic production which is conscious alike of its aim and of the means for attaining it. The more the work grows in definiteness in the thought and under the hand of the artist, the more it will repress and subdue the chaotic tumult of emotional excitement.

The art impulse, in its broadest sense, must be taken as an outcome of the natural tendency of every state of feeling to manifest itself externally, the effect of such a manifestation being to heighten the pleasure and relieve the pain.

Various other influences have all along been at work which have determined the concrete forms of art. Groos has rightly laid stress on the play-impulse, which has been of incalculable importance in the history of art; but there are also, for example, the impulse to attract by pleasing and the imitative impulse. Dramas may have been composed, pictures painted, or poems made in play, or out of a desire to please, or out of an inborn taste for mimicry.

Among primitive peoples, the dance, the pantomime, and even ornament, have been of great importance as means for the dissemination of information. Although

there is but one step between the impromptu dance or poem which tells of a recent occurrence and the work of art which transmits the memory of that occurrence to posterity, yet it appears that there are savages who have no historical art. On the other hand, the historical art has everywhere reached its highest state of development amongst nations who have had to hold their own against neighbouring tribes.

Before discussing the problems of art and sexual selection, of the origin of self-decoration and of erotic art, the author devotes a chapter to a consideration of animal display, and his treatment of the subject is worthy of the attention of zoologists. He arrives at the conclusion that human sexual selection did not create any quality of beauty and that human decoration, like that of animals, is mainly an advertisement of likeness of kind; but, strange as it may appear, scarcely any form of dress or ornament can be quoted which could be considered with certainty an outcome of the impulse to attract or charm the opposite sex. Decorations of various kinds are conferred on young people on attaining puberty, and indicate a new social status, and various subsequent advances in rank have their appropriate decoration. The impulse to ostentation with regard to rank, valour or wealth is undeniably independent of sexual selection. Even where there is no competition between rivals, sexual emotions may still find an artistic expression. Like the courting display of many birds, men may have resorted to song and dance as a mode of overcoming the instinctive coyness of the female after sexual selection has operated; but the strong emotional tension of such periods must in any case seek relief by sound or movement.

It is evident that a pantomimic imitation of any activity must, as exercise and stimulation, facilitate the subsequent real execution of the same activity. Individuals and nations who have grown familiar in play with the most important actions in life's work have thus acquired an unquestionable advantage in the struggle for existence. This holds good alike for the everyday occupations of life as for war. Music and song have especially been useful stimuli to work, partly to overcome natural laziness or inertia, partly to effect unison in the actions of several workers; for instance, the regularity of the action of many peoples is explicable as a result of the rhythmical songs by which their work is accompanied. This applies with equal force to war; hence it is not surprising to find highly developed choral dances in those peoples in whose life war is a customary occurrence. The need of stimulation is never so great as when a man has to risk his life in an open battle, and with this end in view the military singers of some tribes are able to work themselves and their audience up to a pitch of frenzy which is almost equal to that produced by the dances. Courage is also induced by the effort to appear formidable and courageous. Instruction in grimacing even formed a part of the military education of the Maoris. Hence, too, the frightful decorations which so many peoples employ when going on the warpath and the well-known face-shields of some of the tribes of New Guinea and Borneo. The decorative art of warlike peoples is usually characterised by a vigour and originality which dominate also their poetry and dramatic dances, and which are the outcome of an intense and forcible life; but descriptive and figurative art, in the sense of realistic, faithful rendering of nature and life, has never attained any high development among the most military tribes.

Sympathetic magic which is based upon a likeness between things calls forth imitations of nature and life which, although essentially non-æsthetic in their intention, may nevertheless be of importance for the historical evolution of art. Nor is this confined to the primitive or decorative arts. There are many magical dances and pantomimes, and there is an universal belief in the efficacy of incantations and in magical songs and poems.

Every man seeks automatically to heighten his feelings of pleasure and to relieve his feelings of pain. The artist is the man who finds that he can gain such enhancement or relief, not only by the direct action of giving expression to his feeling, but also by arousing a kindred feeling in others. Hence originates in him that desire to transmit his moods to an external audience, and there also arises the endeavour to give the artistic product a form which may facilitate the revival of the original state in an ever-widening circle of sympathisers.

"Beyond the fact that art has been obliged to avail itself of media which have originally been called into existence by utilitarian, non-æsthetic needs, there lies another fact. To these external 'origins' we can also trace some of the most important qualities which we appreciate in a work of art. In this way it is open to us to explain how several of the virtues of art, as we know it, may be derived from the primitive needs which it subserved; how, for instance, the lucidity of art may find its explanation in art's use for conveying information; how the sensuous and attractive qualities of all art may be traced to the need for propitiating favour; how the power that resides in art to trace and stimulate the mind may be transmitted from the days when the artist was appointed to nerve his fellows for work or war. And, lastly, it might be argued that a most characteristic quality of art—the imagination—which is in a sense faith in the reality of the unreal, may have been immensely heightened by the use of art for purposes of magic, which fuses the visible and the invisible."

ALFRED C. HADDON.

THE PARTIAL DIFFERENTIAL EQUATIONS OF MODERN MATHEMATICAL PHYSICS.

Die Partiellen Differentialgleichungen der mathematischen Physik. Nach Riemann's Vorlesungen. Fourth edition. Revised and rewritten by Heinrich Weber. Vol. i. Pp. xvii + 506. (Brunswick: Friedrich Vieweg und Sohn, 1900.)

THE lectures, delivered at the University of Göttingen by Prof. Bernard Riemann in the sessions of 1854-55, of 1860-61 and in the summer of 1862, have, thanks to the volume brought out after Riemann's death under the editorship of Karl Hattendorff, long ranked among the mathematical classics. The third and last edition of "Partielle Differentialgleichungen" appeared in 1882, and two years ago Prof. Heinrich Weber was entrusted with the task of bringing out a fourth

edition. There were three possible ways in which this task could have been fulfilled. One way was to republish the edition of 1882, with trifling additions and alterations. The second way was to retain the existing text, but to add copious notes together with references to recent developments bordering on the subject of Riemann's lectures. The third way was to write an entirely new book, based, indeed, on the earlier editions, but completely brought up to date by the embodiment of the new methods and problems that have come into existence in connection with discoveries in mathematics and physics extending over nearly twenty years from the date of the last edition, and nearly forty years from the time when the lectures were given by Riemann.

Prof. Weber has adopted the last of these alternatives, and by so doing has produced a treatise which will be invaluable to the modern mathematical physicist. How far the present treatise is to be regarded as a new work written by Prof. Weber may be inferred from the fact that this, the first volume only, covers 506 pages, as compared with a total of 325 in Hattendorff's edition, and all the last 350 pages are new.

The first part, dealing with analytical methods, corresponds more or less closely with the first three sections of Hattendorff's edition. It deals with definite integrals, infinite series and the differential equations of common occurrence in physics, especially linear equations with constant coefficients. In this portion we are indebted to Prof. Weber for an amplification of the treatment of Fourier's series and Fourier's double integral theorem, for a more precise treatment of continuity and for entirely new sections dealing with surface and volume integrals, functions of complex variables and conformal representation, and Bessel's functions, the last named addition occupying forty pages.

The second part is entirely new. In it Prof. Weber discusses linear infinitesimal deformations and then gives us a chapter on vectors, in which the modern notions of "curl" and "divergence" are fully explained, and expressions for the curl of a vector given in orthogonal coordinates. This is followed by sections on theory of the potential, including Green's theorem and potentials of ellipsoids. The next section deals with spherical harmonics, and this is followed by a short summary of the principles of dynamics, including the Hamiltonian equations and least action.

The only branches of physics treated in Hattendorff's edition were conduction of heat, elasticity (including vibrations) and hydrodynamics. The absence of any reference to electricity and magnetism is accounted for by the fact that these subjects, together with gravitation, were treated by Riemann in a separate course, of which an edition was also prepared for press by Hattendorff in 1876. The third part of the present volume forms a treatise on the mathematical theory of electricity and magnetism, for which Prof. Weber is thus solely responsible. The fundamental principles of electrostatics and magnetism are based on the hypothesis of a continuous medium, the electrical and magnetic properties of which depend on the existence at every point of space of certain vector quantities satisfying stated laws; and the subject is thus introduced much after the manner adopted by Hertz. Among the problems depending for their solution upon the method of conformal representation, we notice an application of the transformation of Schwarz and Christoffel to the distribution of electricity on a prism, an example which practically amounts to an exposition of this transformation.

The subject of contact electricity, too, receives ample mathematical treatment. Perhaps, however, the most interesting sections are those dealing with electrolysis; and this interest is largely due to the important part which Prof. Weber himself has played in advancing our theories of this difficult subject. A comparison of these sections, in which the problem of electrolysis is made to depend on the solution of differential equations which Weber integrates in certain special cases, with the fragmentary information contained in text-books of forty years ago, is sufficient indication of the progress which has been made during the past half century in developing new fields of study in applied mathematics, and in coordinating and perfecting the mathematical treatment of electricity.

Steady flow of electricity, and the fundamental principles of "electrodynamics" (as it used to be and still sometimes is called), occur in their proper places in the present volume. No mention, however, is made of Hertzian oscillations, which are to be dealt with in the forthcoming second volume in connection with the theory of oscillations in general. The remaining subjects to be treated in the latter volume include conduction of heat, hydrodynamics and elasticity.

Mathematicians will, of course, not be satisfied with the present treatment of such matters as convergence of series and of integrals, and on the other hand physicists will require to supplement the volume with other works containing a fuller consideration of the experimental aspect of the various theories. It was no purpose of Prof. Weber's to aim at completeness in either of these respects. The object of the book is rather to furnish a statement of results both in pure mathematics and in physics, and to indicate the methods by which the former results, used in conjunction with the latter, lead to the mathematical solution of physical problems. As an illustration of the spirit of the book, we may notice the article on semi-convergent series, where the use of these series is explained mainly by the consideration of an illustrative example. Again, as Prof. Weber points out, there are many physical problems which can only be solved by approximate methods of little or no mathematical interest, and these again are omitted.

Now a book of this character appeals to a considerable class of present-day physicists. Forty years ago physical laboratories hardly existed, and the pioneers of physics in this country were Cambridge wranglers who approached the subject from its mathematical side exclusively. Now that physical laboratories are scattered all over the country, and that the working man can attend science classes close to his own door, we are running to the opposite extreme, and there is an ever-increasing class of student who requires to master the mathematics required for his physical studies, but who starts his mathematical reading too late in the day to work up step by step from the very beginning. As was pointed out by Riemann

in the introduction reproduced in Hattendorff's first edition, a science of physics (or more literally "a scientific physics") first existed after the discovery of the differential calculus. A sound knowledge of the differential and integral calculus is assumed in this book, but in Germany such a knowledge is acquired by the majority of students at the commencement of their academic curriculum, a stage where, in this country, many students are still attending lectures on fractions, highest common factor and Euclid. Those possessing the necessary preliminary training will find in Weber's new edition of Riemann an excellent introduction to the methods of applying mathematical principles to the problems of modern physics.

G. H. B.

THE CLASSIFICATION OF EARS.

The Human Ear, its Identification and Physiognomy. By Miriam Anne Ellis. Pp. x+225. (London: A. and C. Black, 1900.) Price 3*s.* 6*d.* net.

A SIMPLE, workable, absolutely trustworthy system is still urgently wanted for the detection of criminals, and if the authoress of this book has succeeded she certainly deserves the thanks of all the Governments of Europe. Whatever worth her method may have when it comes to be applied practically, it has some decided drawbacks when the data are examined on which it is founded.

It so happened that about seven years ago the reviewer came to the conclusion that the external ear ought to yield some clue to the relationship of man and ape, and of one race of man to another. As is well known, the characters of the ear are fully inherited, and afford fairly trustworthy clues to family relationship, of which the authoress gives some good illustrations. Founding his method of observation and classification on data derived from a study of the development and comparative anatomy of the external ear, the reviewer proceeded to examine by hundreds the various peoples and races living on the shores of the North Sea, first on the Continental side, then on the British, to see how far the data he accumulated would support the semi-traditional accounts available concerning the early Saxon invasions of Britain. These observations were continued into the Highlands of Scotland, to Ireland and Wales. To test the "criminal-mark" theory of Lombroso and many others, he examined the ears of more than 800 confirmed criminals, and of more than two thousand inmates of asylums for the insane, situated in parts of the country where he had already examined the ears of the sane. Altogether the ears of more than 40,000 people of different races and of different moralities, besides those of about 300 apes and anthropoids, were examined, but the total results of this elaborate investigation were almost entirely of a negative nature.

The authoress appears to take it for granted, and evidently has not inquired into the matter, that the ear of the criminal is peculiar. If the reviewer's methods and observations are correct, the confirmed criminal's ear is the ear of the average inhabitant of Great Britain. Nor did the ears of the insane differ, on an average, from those of the people from which they were drawn, and if the authoress had carried her observations over a number of men of genius or of high ability, instead of drawing elaborate deductions from single observations, she would probably have arrived at a similar conclusion as to them.

The great difficulty in a matter of this kind is to arrive at a method of classification, and it is in this that all the systems propounded break down when applied practically, and the system propounded here is worse than those that have gone before it. In her classification, the first division is a separation of ears into (1) large; (2) medium; (3) small. Unfortunately, she proposes no definite measurements, but if she did it would be found that a great proportion of ears fell on the limits of the medium line, and it would be a matter of the greatest difficulty to say to which of the great divisions it belonged. There is another great obstacle to the application of measurement of the ear to detection of criminals, of which the authoress is unaware. As Schwalbe showed years ago, and as the authoress may verify any quiet half hour during sermon time, the ear, in the later decades of life, undergoes a very considerable growth—enough to shift the ear of a woman aged forty from the medium division to the large division when she is aged sixty.

The authoress has used one of the most variable and untrustworthy features of the human ear for the purpose of subdividing and indexing the forms in which it is found. She detects in its helix (the upper and posterior border of the ear) five divisions, separated by indentations more or less marked. The three great groups of large, medium and small ears are subdivided according to which and how many of these divisions of the helix are present. In many cases no two observers would agree as to the number of helical subdivisions present, which is not remarkable when it is remembered that the helix on the posterior border is a vestigial structure, the result of the infolding of the free margin of the ear. The amount of infolding does not indicate, as the authoress supposes, certain psychological peculiarities, but merely the degree of retrogression in the ear examined. Like all truly vestigial structures, the infolded margin of the helix is subject to such a variety of forms that it defies classification.

One or two interesting, although minor, points might also be mentioned. The statement that the length of the ear depends on the length of the nose, and that the measurement of the one is identical with that of the other, will be found, on trial, to be the exception and not the invariable rule. In most anatomical works the relation of the breadth to the length of the ear is used as a method of classification; quite a useless one, in the reviewer's opinion. The statement made here is that "the width of the pinna should be at its middle part exactly half its length. . . . Any deviation from these exact measurements at once forms a valuable aid in identification." The scientific part of this book was read in the Anthropological Section at the meeting of the British Association at Bristol in 1898, and many of the observations it contains were made on the ears of eminent men of science. The authoress proposes the term of "otomorphology" to cover the science of the external ear, but from the phrenological character given it by this work perhaps the name of "earistry" were better.

A. KEITH.

OUR BOOK SHELF.

Die moderne Entwicklung der elektrischen Principien. Fünf Vorträge von Prof. Dr. Ferd. Rosenberger. Pp. iii + 170. (Leipzig: Johann Ambrosius Barth, 1898.)

THESE lectures formed a course given to school teachers at Frankfort during the Easter vacation, 1897. Published in book form, they furnish an excellent, though brief, historical survey of the development of electrical theory during the past three centuries. Of all those who have aided in this development, probably none played a more important part than Faraday, for it was he who really laid the foundation of the immense structure of modern theory. This is fully recognised by the author of the present volume, who gives due prominence to the work of Faraday and its influence in the development of electrical principles.

The first two lectures are occupied with the various forms of fluid theory of electric action in vogue down to the early part of the nineteenth century. Beginning at the time of William Gilbert, who may be said to be the first to make any attempt at a physical explanation of electric attractions, we are led through a long series of writings extending to the time when Ampère stated the laws of the magnetic action of electric currents, and brought the subject into the state in which it was found by Faraday. The whole of the third lecture is devoted to the life and experimental work of Faraday, and the great change which he brought about in electrical theory by his introduction of the notion of lines of force. How Faraday's method was so successfully followed by Maxwell, Hertz and others is ably described in the fourth lecture. In an amusing section which here follows, and the significance of which is obvious, the author describes the astonishment of the inhabitants of Mars at the wonders of a railway system established there by an enterprising company of earth-folk, and the elaborate dynamical theories with which the wise men of that planet sought to explain the phenomenon. The fifth lecture contains some exposition of the fundamental principles of mechanics and their relations to electricity. The book is throughout written in very readable style, and its value is much enhanced by numerous extracts from original papers. With the exception of certain instances of misspelling, notably in extracts from English writings, it is free from inaccuracies.

The Birds of Africa. By G. E. Shelley. Vol. ii. Part 2. (London: R. H. Porter, 1900.)

IN this portion of his great undertaking, Captain Shelley commences with the genus Promerops and concludes with the pipits, so that he is still far from coming to the end of the Passerines. In the seven exquisite coloured plates with which it is illustrated, Mr. H. Gronvold fully maintains the high standard of their predecessors, and the text is as full and complete as in the earlier parts.

In his preface the author takes occasion to explain the somewhat unusual arrangement of the Passerines he has seen fit to adopt. "I begin," he writes, "with the Passeriformes and follow on with the Piciformes. The two families of these separate orders which appear to me most nearly allied are the swallows and the swifts, so as I end the Passeriformes with the Hirundinidæ it entails beginning the classification with the Oligomyodæ." This, of course, renders matters perfectly clear. But, we venture to think this half-hearted approximation of the swifts to the swallows is begging the question. Either they are nearly allied or they are not. If the former be the case, they should be placed in the same order. If the latter, the superficial resemblance between the two groups is entirely due to adaptation, and they should be kept as far apart as possible.

On this point we may quote from Prof. Newton ("Dictionary of Birds") that "it should be always and most clearly borne in mind that, though so like swallows in many respects, the swifts have scarcely any part of their structure which is not formed on a different plan; and, instead of any near affinity existing between the two groups, it can scarcely be doubted by any unprejudiced investigator that the Cypselidæ not only differ far more from the Hirundinidæ than the latter do from any other family of Passeres, but that they belong to what in the present state of ornithology must be deemed a distinct order."

While, therefore, we maintain that the author has been ill-advised in his departure from the ordinary classification of the Passerines, this in no wise detracts from the value of his work in other respects. R. L.

One Thousand Problems in Physics. By William H. Snyder, A.M., and Irving O. Palmer, A.M. Pp. 142. (Boston: Ginn and Co., 1900.)

THESE problems are simple numerical exercises, mostly of an elementary character, on hydrostatics, "tenacity and elasticity," statics and dynamics (including gravitation and pendulums), light, sound, heat, expansion of gases, magnetism and electricity. Such a collection of questions should be of much use for class-room exercises. The best way of learning the fundamental principles of elementary physics is undoubtedly to practise making numerical calculations with them, and the large number of questions will enable the book to be used with different classes. Many of the questions could almost be used as oral exercises.

A few questions strike us as being somewhat ambiguously stated. Thus: "A boat weighing 2 tons is moving at the rate of 10 miles per hour when the engine breaks. If the coefficient of resistance of the water is $\frac{2}{5}$, how far will the boat go before it stops?" Even if it is not considered necessary to specify the law of variation of the resistance with the velocity, the units in terms of which the coefficient of resistance expressed should be given, for the result will depend on whether this coefficient represents $\frac{2}{5}$ of a ton at a velocity of 1 mile per hour or $\frac{2}{5}$ of a pound at a velocity of 1 foot per second. Again: "Two strings 6 and 10 feet long, meeting at a point and making an angle of 60°, support a 50 lb. weight. What is the tension on each string?" Here the result depends, not on the lengths of the strings which are given, but on their separate inclinations to the vertical which are not given and cannot be found without further data. The teacher will have little trouble in avoiding these questions.

Peach-leaf Curl: its Nature and Treatment. By Newton B. Pierce. (*Bulletin* No. 20, U.S. Department of Agriculture; Division of Vegetable Physiology and Pathology.) Pp. 204; plates 30. (Washington, 1900.)

THE disease known as peach-leaf curl is due to a fungus called *Exoascus deformans* (Berk.), and seems to be more or less common and destructive wherever peach-trees are grown. It is almost confined to the peach and nectarine and their derivatives; and although its country of origin is uncertain, it has long been known in Europe, and latterly elsewhere. In some countries, as in New Zealand, it has almost extirpated the peach-tree of late years, while the losses from the disease in the United States are said frequently to amount to several thousand dollars annually. The volume before us deals with the subject with the usual American thoroughness. The fungus itself, and the diseased condition of peach-leaves induced by it, are fully described and illustrated, as well as the best means of counteracting its ravages, chiefly by spraying the trees. Although the book is written primarily for the benefit of peach-growers in the United States, it is well worthy of the attention of fruit-growers in other countries where peach-trees are infested by the disease.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Size of the Brain in the Insectivore Centetes.

I do not think that there is any recent mammal which has so small a brain in proportion to the size of the skull as has *Centetes ecaudatus.* In an individual of this species, the property of the Hon. Walter Rothschild, which was lately living in the Zoological Society's Gardens, I found the total length of the brain to be 28 mm., of which no less than 8 mm. were taken up by the enormous olfactory bulbs. The dried skull of that individual—measured along the base and not taking into account the projecting occipital region—was 96 mm. The greatest diameter of the brain is 16 mm.; the skull in that region is from 28 to 40 mm. broad. The small size of the brain relatively to the skull has been frequently commented upon and figured in certain of the early genera of Ungulate mammals; and it may be noted that the measurements which characterise *Centetes,* undoubtedly an early type of mammal, are by no means unlike those of such a genus as *Coryphodon*, judging, that is to say, by the published figures of the brain cast and skull of that animal. The resemblance is increased by the small size of the cerebral hemispheres, and by the *complete* exposure of the corpora quadrigemina in *Centetes.* I hope shortly to give a fuller and illustrated account of the brain of this Insectivore. FRANK E. BEDDARD.

Thermochemical Relations.

In a letter in NATURE of February 7 (p. 348), Signor Carlo Del Lungo calls attention to certain thermochemical equalities, and asks for an expression of opinion as to whether these are the result of a casual coincidence or of a definite law. The equalities in question, if they were not accidental, would have an extremely important bearing on thermochemistry generally, but unfortunately, I believe, they are probably mere accidents of coincidence.

The two instances given would seem to indicate that when two elements combine together, the heat evolved is equal to the sum of that which is liberated when these same two elements combine separately with some third. Thus we have (modifying Signor Del Lungo's equations so as to indicate more clearly that the heat of combination refers to that of the elements taken in their ordinary molecular condition):—

$$\begin{array}{ccccc} \tfrac{1}{2}(2Cl_2, O_2) & + & \tfrac{1}{2}(2H_2, O_2) & = & (H_2, Cl_2) \\ -14 \text{ Cal.} & + & 58 \text{ Cal.} & = & 44 \text{ Cal.} \end{array}$$

and

$$\begin{array}{ccccc} (2H_2, C_{\text{sol.}}) & + & (O_2, C_{\text{sol.}}) & = & (2H_2, O_2) \\ 19 \text{ Cal.} & + & 97 \text{ Cal.} & = & 116 \text{ Cal.} \end{array}$$

I have little doubt but that such coincidences might be shown to be accidental by the existence of similar sets of compound, the heats of formation of which show no such relationship. Unfortunately, I have with me no thermochemical works to supply the requisite data. An examination of the above instances, however, will, I think, suffice to prove that the coincidences cannot be the result of any definite law.

When we expand the first of the above equations so as to represent all the stages involved, and the combinations and separations of the atoms in the various molecules, we get:—

$$[-(Cl, Cl) - \tfrac{1}{2}(O, O) + (2Cl, O)] + [-(H, H) - \tfrac{1}{2}(O, O) + (2H, O)] = [-(H, H) - (Cl, Cl) + 2(H, Cl)],$$

which simplifies into

$$(Cl_2, O) + (2H, O) = (O, O) + 2(H, Cl).$$

This would mean that any pair of the four groups of atoms in the following diagram would combine together in any way, and yet liberate the same amount of heat—*i.e.* the thermal result would be the same whether the products were oxygen gas and hydrogen chloride, or water and hypochlorous anhydride.

$$\begin{array}{c|c} O & 2Cl \\ \hline O & 2H \end{array}$$

This, if established as a generality, would be of fundamental importance. But it is inherently improbable, and the existence of the second instance given by Signor Del Lungo seems to render it untenable. If it were true as regards the gases figuring in the above reaction, it would certainly not be true if one of the products concerned were in the solid condition; if, for instance, we dealt with solid instead of gaseous oxygen, there would be a divergence from equality equal to the heat of condensation and solidification of oxygen. Yet the second instance given by Signor del Lungo contains terms of this very character. When treated as above, assuming for the sake of simplicity that solid carbon molecules contain only two atoms, it gives

$$\begin{array}{c|c} C & 2O \\ \hline C & 4H \end{array}$$

Thus the two instances given, inasmuch as they are necessarily dissimilar, must by their coincidence show that this coincidence is the result of accident, and not of any thermochemical law.

Woolacombe, February 12. SPENCER PICKERING.

The Fraunhofer Lines in the Spectrum of the Corona.

In some of the preliminary reports of the observations made during the last eclipse, undue importance appears to have been attached to the supposed absence of the Fraunhofer lines from the spectrum of the corona. Mr. Newall, for instance (*Roy. Soc. Proc.*, vol. lxvii. p. 365), says, "it is difficult to reconcile the marked polarisation (of the coronal light) evidenced in this investigation with the absence of Fraunhofer lines in the spectrum of the corona." Mr. Abbot, whose bolometric observations appear to him to indicate that the corona does not reflect much solar light, states that "additional evidence against the theory of reflecting particles is found in the Indian eclipse spectroscopic results of Campbell, who found a continuous spectrum from the inner corona with total absence of dark lines" (*Astrophys. Journ.*, vol. xii. p. 75).

Prof. R. W. Wood (NATURE, vol. lxiii. p. 230) has already suggested a partial reconciliation of the apparently conflicting observations, but there are other points which do not seem to have received sufficient attention.

It must be remembered that the Fraunhofer lines were observed in the corona of 1871 by Janssen, and were subsequently photographed by Schuster in 1882, and by Hills in 1893, besides having been seen by various observers on other occasions. Great weight seems to have been attached to the photographs taken in 1898 and 1900, in which no dark lines were recorded, but I venture to suggest that the apparent absence of the lines on these occasions was mainly due to the use of spectroscopes of too great a dispersion to exhibit them. While great dispersion is well adapted to render the bright line spectrum more effective, it is clearly fatal to the dark line spectrum, as in the observation of solar prominences. As a matter of fact, the recent photographs only show continuous spectrum extending to a few minutes from the sun's limb, and if one may take the evidence of the prismatic cameras, this arises mainly from the bright line giving inner corona, which probably does not shine chiefly by reflected light, and would, therefore, not necessarily show the Fraunhofer lines. This view accords well with Schuster's account of the photograph of 1882, in which it is stated that near G there was a sharp decrease in intensity at 0·29 of the solar radius from the limb, a further falling off in intensity at 0·60, with the spectrum fading out of view at 1·47; in the lower regions the spectrum was perfectly continuous, but in the upper regions the solar line G was reversed. Captain Hills also found, in 1893, the Fraunhofer lines only at a considerable distance from the limb. Stone, too, in 1874, observed the dark lines in the outer, but not in the inner corona. In these early observations and photographs we may take it that the dispersion of the spectroscopes employed was much less than in 1898 and 1900, and it would therefore seem desirable to search for the Fraunhofer lines in the next eclipse with instruments of smaller dispersion than those recently in use for the bright line spectrum and special observations.

It may be further remarked that as we do not see a section of the sun, the outer corona must be superposed upon the inner, and the fact that the Fraunhofer lines have not been observed or photographed in the inner corona, even with small dispersion, is sufficiently explained by the superposition of the dark line spectrum on the much stronger continuous spectrum of the inner corona. Such superposition would, of course, be more effective

in obliterating dark lines than bright ones. Prof. Wood's suggestion as to reducing the effective intensity of the truly continuous spectrum by passing the light through a suitably placed Nicol's prism, would accordingly be specially applicable to the inner corona.

Prof. Wood has obtained experimental evidence on a point to which attention was drawn many years ago by Ranyard (*Mem.* R.A.S., vol. xli. p. 353), namely, that if the solar light be reflected by small particles in the corona, the reflected rays will be deficient in the rays of greater wave-length. In this way the bolometric observations indicating that the corona was cooler than the bolometer are partly explained. Is it possible that the observations are to be completely explained by further supposing that the bolometer strip was outside the image of the shallow inner corona, which is probably the chief part of the corona directly emitting light and heat? The image thrown on the strip appears to have been little more than one-third of an inch in diameter, and in the account of the observations Mr. Abbot simply states that the image was brought almost tangent to the strip, so that the strip may very well have been 4 or 5 minutes from the sun's limb.

At all events, there seems to be no sufficient ground, as yet, for rejecting the view that the luminosity of the outer corona is largely due to reflected solar light, while that of the inner corona is partly due to the incandescence of solid or liquid particles and partly to gaseous radiations. A. FOWLER.

Royal College of Science, South Kensington, February 9.

Malaria and Mosquitoes.

I THINK most of those who have had much experience of the Indian jungles would be prepared to corroborate the remarks made by Mr. D. E. Hutchins in last week's NATURE (p. 371), and would perhaps be inclined to think there may be something in the opinion alluded to by him, that "Dr. Ross's splendid discovery does not quite cover the whole ground." In 1873-4 I spent some months in the notoriously malarious region at the foot of the Darjiling Himalayas, which contained some tea gardens here and there at that period, while many new ones were being opened out. The planters suffered greatly from malarial fever, and I was told by several that it was far more prevalent, and of a worse type, on gardens in process of formation, by clearing the jungle and breaking up the ground, than on either the undisturbed jungle itself or on gardens that had existed for some time. In other parts of India my camp has suffered badly from malarial fever when mosquitoes were certainly not prevalent, and when, to the best of my belief, there were none, or perhaps I should rather say, none made themselves noticeable by stinging.

On the other hand, when in Upper Assam in 1874-5, I was informed by some of the planters there, and it seemed to be a commonly received opinion, that mosquito curtains were a valuable protection from malaria. Of course at that period no explanation could be given for the supposed fact, which seemed a very mysterious one, as for the invisible 'germs,' which were thought by some to float in the air, to be excluded by curtains of ordinary mesh would be something like a man being prevented from crossing a road through inability to squeeze himself between the milestones.

18 The Common, Ealing, February 12. F. R. MALLET.

Audibility of the Sound of Firing on February 1.

THE following note was recorded here (at Littlemore, Oxford) immediately after I was called away from listening; and as it is more detailed than any I have seen, I daresay you will think it worth printing.

I held my watch in my hand and observed the sequence of the booms for some ten or twelve successive minutes. The second one showed there was regularity, and after the third the facts were clear. The sounds reached us thus:

0s. to 20s., continuous unbroken roll of guns of slightly different strength.

20s. to ± 24s., silence for 4s. or 5s.

± 24s. to ± 29s., similar roll.

± 29s. to ± 34s., silence for 3s. or 4s.

± 34s. to ± 38s., a similar roll.

± 38s. to 42s., silence to just the 42s.

42s. to 45s. exactly, a short roll culminating in three or four guns *much* louder than any of the preceding ones.

45s. to 60s. exactly, dead silence for a quarter minute.

This recurred with such perfect regularity that there was no doubt whatever about the precision of the observation.

Then I had to ride away on a bicycle about a mile, where I met another cyclist, and we stopped and listened again. The long 20s. roll was now missing, but punctual to the second or two came all the others, the last one with big guns precise.

It seems likely that the long roll was the *simultaneous* salute of the long line of ships; but I have not yet noticed any authoritative statement as to how the saluting was done. It was interesting to think that at any moment while we were listening there were no fewer than six other such salutes travelling up towards us from the Solent.

From the strength of the sounds I should quite agree with the opinion expressed in Oxford that they might well be heard another twenty miles. W. J. HERSCHEL.

February 12.

The Origin of the "Tumbling" of Pigeons.

IN reading the account of tumbler pigeons in Darwin's "Animals and Plants under Domestication," the question arose to what the habit of "tumbling" might be due.

I have since seen, in a report of an address by Prof. J. A. Thomson to the North British Branch of the Pharmaceutical Society, a statement that the peculiarities of movement of the Japanese waltzing mouse are due to the fact that only one of its semi-circular canals is developed.

It occurred to me that a similar condition might explain the movements of the tumbler. I should be much obliged if you or any of your readers could tell me where information concerning either of these examples is to be found. E. P.

February 3.

[Prof. Thomson's statement is not quite accurate. The paper to which he referred is undoubtedly that by Rawitz, in *Archiv. f. Anat. and Physiol.* (Physiol. Abth.), 1899, pp. 236-244, where it is shown that of the three canals the anterior is alone normal, and that the other two—though reduced and abnormal in their inter-relationship—are present.

The physiology of the organ has been since experimentally investigated by Alexander and Kreidl, whose paper is in Pfluger's *Archiv. f. Ges. Physiologie* (Bd. 82, pp. 541-552); and as to the pigeons, they, too, have all three canals well developed. Concerning their membranous labyrinth, some experiments of interest were made in, I think, the early nineties by Spamer and others, and an account of these and of allied investigations bearing on the question raised (by McBride) will be found in the *Journ. Anat. and Physiol.* (vol. xvii. pp. 211-217). There does not appear to be any foundation for the view to which the writer of the letter inclines.—G. B. HOWES.]

Lummer's "Photographic Optics."

THE interesting review of Prof. Silvanus Thompson's translation of Dr. Otto Lummer's "Photographic Optics," which was published in NATURE on January 3, has come under my notice. I should be obliged if you would permit me to correct a mistake which occurs both in Prof. Thompson's book and the review. Concerning the two views of Munich published in Prof. Thompson's work, which are there attributed to Dr. Miethe, you remark: "Miethe's two views of Munich from a distance of about two miles—the one taken with an ordinary lens, the other with the teleobjective—show what a powerful weapon the latter is."

Both the views in question were taken by my firm, one with an antiplanet and the other with this antiplanet in combination with a magnifying system (negative lens) as a teleobjective of our own construction and manufacture. I send you a prospectus of my firm concerning the said teleobjective and containing also the two views of Munich.

I also observe another error in Prof. Thompson's work; the lenses recently introduced by Messrs. R. and J. Beck being described on p. 80 as Messrs. Voigtländers' Collinears, instead of our orthostigmats, for which I have given them a manufacturing license, as you will see in the notice on page 1 of the prospectus I also send by book post. RUDOLF STEINHEIL.

München, February 5.

NOTHING could have been further from my intention than to do any injustice to Dr. Steinheil or his firm, and I hasten to acknowledge the justice of his criticisms upon the slips

contained in my edition of Lummer's book—slips for which I take the entire responsibility. The error on p. 100 in supposing that the Munich view was photographed by Prof. Miethe, of Berlin, arose from a confusion between two sets of telephotographic views sent me from Germany, some of which were taken by Prof. Miethe. I would point out that, in the only case in which the kind of lens used is stated, it is correctly stated to be a Steinheil's lens. I presume Dr. Steinheil is not dissatisfied with the performance of the lens in producing the picture, by whomsoever it was photographed. The other point arose from inserting at the last moment, when the sheets were going to press, a reference to Messrs. R. and J. Beck, which should have been inserted at the end of paragraph four instead of paragraph three of Chapter xi. Let me assure Dr. Steinheil that both points will be corrected in any fresh issue of the text.

February 9. SILVANUS P. THOMPSON.

The Ash Constituents of Some Lakeland Leaves.

ALTHOUGH it cannot be maintained that the amount of inorganic matter which the leaves of a tree extract from the soil on which it grows is quite independent of the chemical composition, &c., of that soil, it was deemed advisable to perform a few experiments bearing on this particular feature. Notwithstanding the considerable elevation, viz. about 400 feet, the soil in this locality is distinctly suited and adapted to the growth and healthy development of most of our well-known forest trees. It is a cold, basic clay, mostly not very stiff, on account of the presence of some gravel and peat in many places, and, generally speaking, enriched with considerable quantities of potash, silica and manganese, while a serious deficiency in lime is attested by the universal prevalence of distinctly calcifuge plants. The percentage of crude ash set down in the subjoined table was calculated from the combustion of the leaves gathered in the evening, dried first in the air and then at 100° C. The details are as described :—

Leaves of	Date	Percentage of crude ash	Percentage of lime (CaO) and of silica (SiO_2) in the crude ash
Sycamore ...	May 16	5·6	
,, ...	July 5	6

The steady increase in the quantity of ash in the leaves of sycamore and wych elm as the season progresses is here exhibited with sufficient emphasis. The peculiarity, however, is that in the case of the sycamore the percentage does not reach the figure that it might do on other soils or under other circumstances; for instance, according to Schleiden and Schmidt, it might come up to 28 per cent.; but this proportion, I make bold to say, is never attained in any part of British Lakeland. The surprisingly large percentage of silica and lime in the ash of the deep crimson leaves and petioles of the rowan demands further investigation, inasmuch as this is a rather calcifuge tree, and the amount of silica in other allied Rosaceans is very small. According to Rismuller, the ash of dry beech leaves is 4·6 per cent. on May 7 and 11·4 per cent. on November 18; whereas Gueymard found that when gathered after natural fall and dried they yield only 5·6 per cent. ash, and my experiments do not warrant the assumption of any serious difference as respects inorganic constituents between the vernal and autumnal foliage of this tree. "Alone among the species of the first order of Mid and North Europe," says MM. Fliche and Grandeau, "the Scots pine seems to seek out siliceous soils, but the physical rather than the chemical conditions of the soil seem, as regards this species, to have a preponderant influence." Nevertheless, the percentage of ash in its first and second years' leaves is precisely the same here as it is in North Germany, and the extremely moderate inorganic pabulum that suffices to sustain it and the birch enables them to bear the privations of an upland abode. P. Q. KEEGAN.

Patterdale, Westmorland.

An Earthquake on February 10.

IN the early hours of February 10, in the town of Grazalema, there was experienced an intense earthquake, with damages to buildings, many of them being rent.

The duration was about three seconds, and the movement a compound one of oscillation and trepidation, accompanied with considerable noise.

The people ran out of the houses full of terror.

The church of Saint Joseph and some other large buildings have been very severely damaged, and also factories and mills.

The body of water that provided motive power for the machinery in one of the factories has disappeared.

Grazalema is a town of 10,000 inhabitants, situated in a hilly district of the province of Cadiz, at about 70 kilometres, nearly due north, from Gibraltar. AUGUSTO ARCIMIS.

Instituto Central Meteorologico, Madrid, February 13.

The late Prof. Hermite.

YOUR interesting memoir of Prof. Hermite differs in one detail from the account in "Men and Women of the Time." It is said there that he was born at Dieuze, in Lorraine, and that he was for a while at Nancy before going to Paris.

W. B. C.

THE RADIO-ACTIVITY OF MATTER.

AT the commencement of the year 1896, in carrying out some experiments with the salts of uranium, the exceptional optical properties of which I had been studying for some time, I observed that these salts emitted an invisible radiation, which traversed metals and bodies opaque to light as well as glass and other transparent substances. This radiation impressed a photographic plate and discharged from a distance electrified bodies—properties giving two methods for studying the new rays.

The phenomenon does not appear to be influenced by any known external cause, such as a variation of temperature or a luminous excitation; it is entirely different from phosphorescence; is not weakened in an appreciable manner by time, even at the end of several years; and is emitted spontaneously without any apparent exciting cause. The radiating property appeared, firstly, to be bound up with the presence of the chemical element uranium; the metal discharges electrified bodies three to four times faster than its salts.

If some fragments of uranium or of one of its salts are placed upon a photographic plate wrapped in black paper or covered by an aluminium leaf, and if between the uranium and the plate various substances are interposed, there is obtained at the end of several hours or days, radiographs showing that the radiation is propagated in straight lines, and traverses different bodies unequally. In the radiographs the edges of the plates of glass, or of thin plates of other substances, throw a sort of shadow, which is still unexplained. This phenomenon, as well as an inequality obtained twice accidentally through parallel and crossed tourmalines, led to the belief at the commencement of these researches that these rays had properties in common with light. But all the later experiments have shown that the new radiation undergoes neither reflection, refraction nor polarisation.

The uranium radiation dissipates with equal rapidity either positive or negative electric charges; the effect is unequally transmitted through screens of different materials according to their nature and according to the order in which they have been simultaneously interposed. This fact leads to the prediction of the heterogeneity of the radiation. The dissipation of the charges of an electrified body submitted to the uranium radiation takes place through the action of the surrounding gas, which is thereby made conducting; the air keeps this property during some instants, and if, after having been influenced, it is blown on to an electrified body, the latter is discharged. A sphere of uranium remains charged if it is placed in a vacuum; in air it puts itself in equilibrium as regards potential with the surrounding space. The rate of leak increases with the potential, and, for high potentials, tends to a constant.

If two conductors are arranged at some centimetres apart, one of which is connected with a source of electricity, and if a piece of uranium is brought near, there is established between the two conductors a continuous current of electricity. Such are the principal facts that I had observed.

In 1897 Lord Kelvin and Messrs. Beattie and S. de Smolan varied the conditions of the preceding experiments, and showed that the uranium radiation established between two metals in air the same equilibrium as a drop of water which united them. In 1899 Mr. E. Rutherford made it clearly apparent that the conductibility set up in gases by uranium was due to a phenomenon of ionisation identical with that which, according to the experiments of Prof. J. J. Thomson, is provoked by the Röntgen rays.

In 1898 the discovery of new radiating bodies gave a new and fruitful impulse to these studies. Mme. S. Curie and M. Schmidt had recognised that thorium possesses analogous properties to those of uranium; then Mme. Curie observed that certain uranium minerals were more active than either metallic uranium or thorium. M. and Mme. Curie concluded from this that there existed other radio-active bodies, and undertook to isolate them.

I cannot analyse here the chemical part of the fine work of M. and Mme. Curie, who, working with the electrometer as the chemist works with the spectroscope, succeeded in extracting from pitch-blende two very active substances: on the one hand, a product containing bismuth and a body which they called polonium; and, on the other hand, a mixture of barium and another new substance, radium.

When they had prepared some centigrams of products the activity of which, progressively increasing, became several thousand times greater than that of uranium, M. and Mme. Curie were good enough to give me some milligrams, so that we could thus pursue parallel researches on the new properties.

M. and Mme. Curie recognised, among other important properties, that these bodies excite the fluorescence of the platinocyanides; that the salts of radium are spontaneously luminous; and further, that all bodies receiving the new radiation become radio-active in their turn, but that they gradually lose this property with time. They observed also, as well as Giesel, who prepared mixtures analogous, but less active, to those of M. and Mme. Curie, that the salts of radium increase spontaneously in activity for some time after their preparation, whilst the activity of polonium salts diminishes. The new radiation produces various chemical actions, alteration of the platinocyanides, violet coloration of glass, production of ozone, &c.

For my part, I have observed that the polonium radiation does not traverse even black paper; it is much less penetrating than that of radium, which, moreover, provokes in bodies which it encounters a secondary penetrating radiation which marks a photographic plate in the immediate neighbourhood of the points struck. I have been able to establish also that the intensity of the phosphorescence excited by radium varies as the inverse square of the distance of the excited body from the radiating source; that the unequal weakening produced by a given screen on the phosphorescence of different substances furnishes a new proof of the heterogeneity of the exciting radiation; and, lastly, that the radiation of radium restores the property of becoming phosphorescent by heat to such bodies as fluor spar, leucophane, &c., which had lost this property by a preliminary heating.

I would here point out the very interesting researches of M. and Mme. Curie, M. Owens, and of Mr. E. Rutherford upon the penetrating rays of thorium. Mr. E. Rutherford has found that thorium compounds emit, in addition to this ordinary radiation, a very penetrating "emanation" that produces temporary radio-activity in substances in the neighbourhood, if the bodies are all uncharged. With charged conductors the radio-activity is produced on the negatively charged body. The radio-activity can thus be concentrated on the surface, of thin wires, and removed by hydrochloric and sulphuric acids, whose solution, when evaporated, leaves the active portion behind. Thorium may perhaps owe a part of its properties to a new element, actinium, discovered in 1900 by M. Debierne, and which is as active as radium.

At the end of 1899 several observers discovered, nearly simultaneously, that the rays from certain radiating substances were deviated by a magnetic field. This was first shown by M. Giesel with preparations of polonium and radium, then by MM. S. Meyer and E. v. Schweidler, who some days later showed the same thing with preparations made by M. Giesel, and then, a little later, without having any knowledge of these observations, I recognised that the radium radiation concentrated itself upon the poles of a non-uniform magnetic field, whilst the radiation of polonium prepared by M. and Mme. Curie is not deviated. The preparation of polonium of M. Giesel was, then, not the same substance as that of M. and Mme. Curie.

It resulted from these observations that there exists two kinds of radiations, one not capable of deviation and of which the nature is still unknown, the other capable of deviation, which later experiments have identified with the kathode rays. Somewhat later, M. and Mme. Curie recognised that both these rays coexisted in the radium radiation. The non-deviable rays are much less penetrating than the deviable rays; the polonium radiation is limited in air to a kind of sheath of some centimetres in thickness. I might add that recently M. Villard has proved the existence in the radium radiation of very penetrating rays which are not capable of deviation. M. Debierne has recognised that actinium emits some deviable rays.

I have devoted numerous experiments to the study of the deviation of radium in the magnetic field. This radiation is dispersed by the field into rays of different natures, like as light is dispersed by a prism. For each simple radiation, the trajectory in a plane perpendicular to a uniform field is a circumference of radius R, which brings back the radiation to the point of departure. If the radiation makes at the origin an angle a with the axis of the field, the trajectory is a helix rolled on a cylinder parallel to the field and of radius R sin a. The product $H\rho$ of the component of the field normal to the displacement at a point, by the radius of curvature of the trajectory in this point is constant, and may serve to characterise each simple radiation.

To obtain a beam in which each simple radiation would have a unique trajectory, a radiant source may be taken of very small diameter, the radiation being received after traversing a narrow gap in a sheet of lead.

It is shown by experiment that it is sufficient to arrange between the polar pieces of an electromagnet a horizontal photographic plate upon which is placed, in the centre of a little leaden dish, the radiating source of very small diameter. The rays emanating normally to the plate and brought back orthogonally on it are the most efficacious; the impression, large and diffuse, is thrown on one side of the field, and constitutes a sort of spectrum which is sufficiently pure. If one works in the dark, and places on the photographic plate bands of various substances, aluminium leaf, copper and platinum foil, &c., it is seen that under the screens the impression of the deviated rays is limited by elliptic arcs, distinguished from each other. Each screen arrests different radiations, the most deviated being the most absorbable. The dimensions of the elliptic arcs are in accordance with theory. The absorption is the same in air and in an absolute vacuum. These experiments constitute a sort of magnetic spectrum analysis of the deviable radiation.

The identification of this radiation with the kathode rays requires two other verifications—the demonstration of the existence of a transport of electric charges and that of a deviation in an electrostatic field. M. and Mme. Curie have made the first verification, and I have realised the second. M. and Mme. Curie placed a screen, isolated from all contact with the air, in connection with an electrometer, and observed that the radium radiation charged this screen negatively, whilst the source itself, if it is properly isolated, is charged positively. The current for each square centimeter of radiating surface was about 4.10^{-13} electromagnetic C.G.S. units.

For my part, I showed that in an electric field the radiation of radium undergoes a parabolic inflection in the contrary sense to the field, as would be the case with a flux of negatively charged particles. The comparison of the electrostatic and magnetic deviations allows of the determination, like that of Prof. J. J. Thomson for the kathode rays, of the velocity of the particles. For the particular radiations defined by $H\rho = 1600$, the velocity has been found equal to 1.6×10^{10}—about one-half of that of light. The ratio of the material masses carried off to the charges which they transport has been found equal to 10^{-7}, a number identical with that corresponding to the kathode rays. From these numbers, and that which results from the experiment of M. and Mme. Curie, it follows that for each square centimetre of surface of the radiating substance studied there escapes a flux of material which would amount to a loss of about one milligramme in one thousand million years. If the material emission, which appears to be of the same order as the evaporation of certain scented substances, is the first cause of the observed phenomena, there would be no contradiction between the apparent absence of any source of energy and the continuous emission of this energy.

The most deviable portions of the radium radiation pass easily through all bodies when they are very near the source, but are stopped when these bodies are some centimetres distant. I have further recognised that, after having traversed a screen, the radiation possesses the same magnetic deviability.

I can only give here the physical properties of radio-activity. One of the most important applications has been the discovery, by M. and Mme. Curie, of new chemical elements. Radium has a high atomic weight, and a characteristic spectrum observed by M. Demarçay. Polonium, according to recent researches, has a spectrum in the ultra-violet. These bodies possess, then, the characters of simple substances.

Recent studies on induced radio-activity appear to open still new horizons. It has been mentioned already that a body becomes temporarily active when it receives the radiation of an active body. M. and Mme. Curie and M. Giesel have recognised that the induced activity thus provoked was much greater if the body was mixed in solution with an active salt and then afterwards separated by precipitation. In thus rendering barium active with actinium, M. Debierne has recognised that the active barium behaves as a different body from ordinary barium, that it could be separated chemically and concentrated. Active barium thus resembles radium. It differs from it by the absence of a peculiar emission spectrum and by the fact that its activity weakens with time. I would add that recently Sir W. Crookes, who has made numerous experiments by the photographic method, announced that he had prepared uranium that was almost inactive. According to these experiments, as well as those of M. Debierne, M. Giesel and myself, it would appear to follow that the activity of uranium is due in great part, if not altogether, to a small quantity of actinium or of another radio-active body.

These facts, although increasing the complexity of radio-activity from the chemical point of view, do not, however, remove from it its value; it can be remarked that if the existence of uranium as a simple body had been unknown up to the present, its radiant properties would have permitted of its isolation, even though they are not inseparable from its existence.

This short account shows that a new order of phenomena has arisen from the study of a new property of matter—radio-activity. HENRI BECQUEREL.

PROGRESS OF THE MAGNETIC SURVEY OF THE UNITED STATES.

THE special division of the United States Coast and Geodetic Survey devoted to the magnetic survey of the United States, and countries under its jurisdiction, was created by the late superintendent, Dr. H. S. Pritchett, now president of the Massachusetts Institute of Technology, on July 1, 1899; and Dr. L. A. Bauer was put in charge of the division. Since that date magnetic observations—namely, declination, dip and intensity of magnetic force, have been made up to December 31, 1900, at about 500 stations distributed over the United States, Alaska and the Hawaiian Islands. At most of the stations permanent marks have been established for the use of the surveyor. Special consideration has also been given to the needs of the mariner, especially in Alaskan waters, where occur places of pronounced local attraction affecting the compasses on board ship all the way from $\frac{1}{4}$ of a point to 4 points.

Special stations, known as "repeat" or "secular variation" stations, have also been established in different parts of the United States. At these, observations will be repeated at stated intervals in order to determine the amount of secular change in the magnetic elements. It is the endeavour, whenever possible, to establish such stations in the vicinities of colleges and universities, as experience has shown that on college grounds there is hope for a permanency of station for a fairly long interval.

Of special State surveys mention may be made first of the completion of the magnetic survey of Maryland, which was undertaken primarily by the Maryland Geological Survey and assistance rendered by this Bureau; second, the completion of the magnetic survey of North Carolina, conducted under the joint auspices of this Bureau and the North Carolina Geological Survey; third, the completion of the magnetic survey of West Virginia; and fourth, the completion of the magnetic survey of Iowa.

Fair progress has also been made in the establishment of the magnetic base stations, where the countless variations of the earth's magnetism will be recorded photographically. Thus, a temporary magnetic observatory

has been in operation at Baldwin, Kansas, since July 1, 1900, and the buildings for the primary or principal magnetic base station, situated at Cheltenham, Md., sixteen miles south-east of Washington, have been completed and the installation of the instruments is now taking place. Special declination readings from 7 a.m. to 4 p.m. have been made at Gaithersburg, Md., since March 22, 1900, and at Sitka, Alaska, since October 1, 1900. The sites for the magnetic base stations at Sitka, Alaska, and near Honolulu, Hawaiian Islands, have been determined and preparations made for the erection of the buildings. It will be the endeavour to have these magnetic observatories completed in time for co-operation with the proposed Antarctic expeditions.

Furthermore, special simultaneous observations have also been made on special days at various times, the purpose of these special observations being to determine over how large an area the variations, as recorded at the base stations, may be regarded as applying.

Again, various special investigations both of an experimental and a theoretical character have been undertaken, and considerable attention has been paid to the thorough training of observers and to the proper correlation of the various magnetic instruments. During the autumn of 1899 a set of coast survey magnetic instruments was compared with the standard instruments at the following foreign observatories: Kew, England; Potsdam, Germany; Pavlovsk, Russia; and Parc St. Maur, France.

The following publications have been issued, namely: Appendix 9, giving a general report of the magnetic survey of North Carolina; and Appendix 10, on the magnetic work of the U.S. Coast and Geodetic Survey, both appendices appearing in the Report of the Survey for 1898–99. Good progress has also been made with the new edition of the Coast Survey's magnetic declination tables and isogonic charts for the United States and Alaska for 1900.

MAX JOSEF VON PETTENKOFER.

It is with great regret that we record the death, in very sad circumstances, of the veteran German hygienist, Prof. Max von Pettenkofer. He was born in 1818, and was, therefore, in his eighty-third year at the time of his death.

Pettenkofer's name was known throughout the civilised world as that of the great professor of hygiene at Munich, and he made the Munich school famous. Among medical and hygienic circles in Europe he was personally well known and respected for his fearless defence of what he believed to be true and for the breadth of his views. Sometimes during a discussion on some subject on which he felt strongly, the burly form of the great German hygienist would arise, and with a few vigorous sentences he would scatter the arguments of his opponents like chaff before the wind. A notable instance of this occurred at the meeting of the International Congress of Hygiene and Demography at Vienna in 1887 during the discussion on quarantine; the supporters of that antiquated method of prevention had most of them aired their views, when Pettenkofer got up and brusquely told them that it was a question of cleanliness, that England had spent many millions in improving the sanitary condition of her towns and had now no fear of cholera, and that what other countries should do was to follow England's example, and then they would have no need for the vexatious and, for the most part, useless restrictions of quarantine.

Pettenkofer published a great many valuable papers on public health subjects; the list of their titles fills nearly a page and a half of the great "Index Catalogue of the Library of the Surgeon-General's Office, United States Army"; and even that is not complete, as it does not include his remarkable paper on "Die Immunität von Lyon gegen Cholera." But he was too busy with teaching the many pupils who flocked to him from all parts of the world, and with investigating, to write large treatises, two on cholera being the longest productions of his pen; this, indeed, was his favourite subject, and his books and papers on it number about a score, the best known of them probably being the one entitled "Boden- und Grundwasser in ihren Beziehungen zu Cholera und Typhus," in which he propounds his well-known theory that the spread of cholera and enteric fever depends upon the movements of the subsoil water, their prevalence increasing after a fall in the level of that water. This view he stoutly maintained, undaunted even by the fact that the City of Lyons (the invariable immunity of which from epidemics of cholera, in spite of several introductions of the disease, he considered quite explicable on his theory) was very subject to enteric fever, from which it ought, on the same theory, to be immune.

Whether, however, we regard his ground-water theory as correct or not, we cannot but admire the practical results of the measures taken under his advice to purify the subsoil of Munich, which, from being a hotbed of enteric fever, has become remarkably free from that disease.

He also wrote on sewerage arrangements, on the hygiene of ships, and on "the relations of the air to clothing, dwelling and soil," the last being a course of popular lectures; and he was co-editor of the *Zeitschrift für Biologie* (München) from 1865 to 1882.

Pettenkofer was much interested in chemical work connected with hygiene, and devised the method (ever since known by his name) of determining the percentage of carbonic acid in air, which has been adopted by all observers until quite recently.

Personally he was gentle and amiable, as a little incident will suffice to show. In 1894 the present writer, not finding him at the International Congress of Hygiene at Budapest, went to see him at his home at Seeshaupt, on the Starnberger See, near Munich; he was crossing on one of the steamers, and, when about half way towards the farther end of the lake, was surprised to meet Pettenkofer on board. The latter had gone some distance round the lake by rail and got on the steamer at one of the stopping places, so as to come part of the way to meet his guest for the day and escort him to his house.

Not having received the usual New Year's greetings from him on a card bearing a photograph of one of the fountains of the "Pettenkofer water supply" at Munich, with a small profile medallion of the professor above it, the writer feared that he was not well, but was little prepared for the terrible news which so soon followed.

It was no doubt his retirement, even at that lovely spot, and his forced inactivity, that preyed upon poor Pettenkofer's mind, and not even the patent of hereditary nobility granted him by the Emperor seems to have solaced him, for we have just received the melancholy and pathetic news that this grand old man, tortured by an incurable disease and wearied by his inability to work any more for the benefit of his fellow-men, has put an end to his sufferings by a pistol shot. W. H. C.

THE ROYAL INDIAN ENGINEERING COLLEGE, COOPERS HILL.

Last week we printed a report, taken from the daily papers, of the deputation to the Secretary of State for India asking for an inquiry into the working of the Royal Indian Engineering College. Lord Kelvin, who headed the deputation, expressed disappointment at the nature of Lord George Hamilton's reply, and if, in criticising that reply, we should fall into error in consequence of the inconsistencies in the reports of the

interview, we must apologise to Lord George Hamilton beforehand if we should unintentionally misrepresent him.

The Secretary of State is of opinion that some of those who signed the memorial have been misled by *ex parte* statements; but the memorial was founded solely on the letters of dismissal and the memorial to the Secretary of State sent by the dismissed members of the staff. Lord George Hamilton seems to forget that Colonel Ottley's report is quite *ex parte*, for the staff have not only not had an opportunity of answering it, but they did not know of its existence until the reply of the Secretary of State was given.

We are assured that none of the letters to the daily papers were written by members of the staff, and the letters from the students were unanimously condemned by them.

Lord George Hamilton stated that Mr. (now Sir Henry) Fowler's committee of 1895, the composition of which it would be interesting to know, was of opinion that the number of the staff was out of all proportion to the number of the students, but we are very much mistaken if comparison with other institutions would not show that the number of the staff is by no means excessive. The numbers of the staff must depend more upon the variety of the subjects taught than upon the numbers of the students. In an engineering college especially, if it be worthy of the name, the variety must be considerable. The percentage of staff to students will decrease with the number of students; at Coopers Hill numbers of students are denied admission each year.

Until Colonel Ottley's report is published in full, it will be impossible to judge of the statement that it shows "a very unsatisfactory state of affairs at the College." That this is so is all the more surprising as the College is now self-supporting. More than this, year after year the Secretaries of State have spoken of the satisfactory state of the College when addressing the students on the prize days, and this after receiving the reports of the presidents.

The state of affairs is certainly unsatisfactory from one point of view. A college can no more get on without college meetings of the teaching staff than a Government can get on without Cabinet meetings of those in charge of different departments. Lord George Hamilton's reply indicates pretty clearly that while the teaching staff is never consulted, it is not quite certain whether the governing body is the Board of Visitors or the president of the College, who has made it quite clear that he knows nothing of educational methods.

It is impossible not to come to the conclusion that the main obstacle to improvement in the work at Coopers Hill has been the unsatisfactory position of the staff; they are entirely under the hands or the heel of the president, who may have had no experience whatever in matters of education. The staff are unable to forward recommendations to the India Office except through the president, and however much they may be desirous of improving the teaching, they are powerless.

There seems to be some misunderstanding about the teaching of electrical engineering. Some years ago several members of the staff urged the then president to introduce electrical engineering as a compulsory subject; the president would not further the proposal. It was next suggested that the subject should be made alternative with some of the other third-year work; this was accepted, and since that time many students have worked at this subject for about fourteen weeks in their third year. Two of the members of the staff who are dismissed were instrumental in obtaining this concession from the president and the India Office. It is difficult to reconcile the desire to have electrical engineering as a compulsory subject with the statement in the *Times* that, "with respect to electricity, the India Office had taken the opinion of Sir William Preece, and came to the conclusion that a demonstrator was capable of giving all the necessary instruction," unless it means that electrical engineering is to be taught as an art and not as a science, which will probably result in the students having an insufficient theoretical knowledge of the science they have to apply, and will certainly lead them into difficulties on an emergency.

The reference to Dr. Brightmore would lead a reader of the speech of Lord George Hamilton, as it appears in the papers, to think that he had been appointed recently to take the head of the engineering branch. Some of our readers will doubtless remember that Dr. Brightmore was appointed in September 1899 against the wishes of the late president, Colonel Pennycuick, and that his appointment was the principal cause of the resignation of that officer.

The statement that "the upshot of the whole matter would be this: there would be an increase in the hours of work in class and lecture from twenty-six to thirty-two" hours per week, is extremely misleading. A reference to the College time-tables would show that before the advent of Colonel Ottley the time of study for first year students was thirty-three hours a week, and for second year students thirty-four. At that time the third year students had in lecture only 14 hours 20 minutes; but no account is taken of the project, the engineering and turbine designs, or the architectural design, which latter was alternative with work in the chemical or physical laboratory, and the hours for which do not appear in the time-table. If the numbers of hours actually spent in lecture by students of the three years are added together and divided by three, a number not far from twenty-six is obtained, but it is very disingenuous to insinuate that in the time of previous presidents the students did only twenty-six hours' work a week.

Another effect of the new scheme is said to be the raising of the standard of the entrance examinations. When the College was first opened the entrance examination was conducted by the Civil Service Commissioners; later, when it was opened to all students who desired to present themselves in order to compete for the Indian appointments in the College itself, the examinations were carried on at the College by some members of the staff, and the number of the candidates was often less than the vacancies. As the order has always been given to the presidents to make the College "pay," there was a tendency to admit as many as possible, so as to fill the building. Of late years the number of candidates has exceeded the vacancies, and the examination has been selective, to the great satisfaction of the staff, who thus have better material with which to work. This stiffening of the examinations has been going on for some time, and is quite independent of the recent dismissals or of Colonel Ottley's report.

Another very misleading statement is that 39 per cent. of the students fail; this is made so as to infer that the teaching is inefficient. This number has probably been arrived at by counting the number of students who enter in one year, and the number of the same batch who obtain diplomas at the end of the third year; but no account appears to have been taken of the fact that many students withdraw of their own accord before completing their college course.

The statement that outside examiners would be appointed might induce a casual reader to suppose that the examinations are carried out by the teachers themselves, as, indeed, the *Times* categorically states, "the teachers were also examiners with no one from the outside." This is erroneous; outside examiners have always been the rule; a large proportion of the marks are given by outsiders, and in some subjects as much as half of the marks are so awarded. The outside examiners are absolutely independent; their papers are not seen by the lecturers.

Extracts of the reports of these examiners are read by the president on the prize day.

What we have stated above quite supports Lord Kelvin's expression of disappointment at the reply vouchsafed to the deputation.

It appears also, from Lord George Hamilton's reply, that he does not consider the men of science employed at Coopers Hill to be servants of the Crown, and that consequently a different measure is to be meted out to them than that proper to the unscientific clerks in a department of the India Office. He is reported to have said that the age limit of the professors at the College is sixty; surely, under the Superannuation Act of 1859, it is sixty-five, and the professor may continue in office until seventy if the president certifies that the work is being efficiently performed.

Under the same Act, if it were desired to reorganise the College, there was a regulated way open which, beyond all question, would be the one employed in any reorganisation of the India Office itself; and surely under these circumstances it was the duty of the representatives of science to ask for simple justice. Chap. VII. of the Superannuation Act runs as follows:—

"It shall be lawful for the Commissioners of the Treasury to grant to any person retiring or removed from the public service in consequence of the abolition of his office, or for the purpose of facilitating improvements in the organisation of the department to which he belongs, by which greater efficiency and economy can be effected, such special annual allowance by way of compensation as on a full consideration of the circumstances of the case may seem to the said Commissioners to be a reasonable and just compensation for the loss of office; and if the compensation shall exceed the amount to which such person would have been entitled under the scale of superannuation provided by this Act *if ten years were added to the number of years which he may have actually served*, such allowance shall be granted by special minute, stating the special grounds for granting such allowance, which minute shall be laid before Parliament, and no such allowance shall exceed two-thirds of the salary and emoluments of the office."

Another point that the noble lord appears to have omitted to answer is Prof. Johnstone-Stoney's contention that the dismissals were not even in accordance with the terms of appointment.

If the above assertions are true, and we have every reason to believe that they are, is it surprising that the dismissed members of the staff should ask for further nquiry? And it is only natural that others, as represented by the signatories of the memorial presented on Tuesday week, should wish to support their application. It would appear that the inquiry is even more urgently needed since we have heard Lord George Hamilton's reply.

But the condition of the staff at Coopers Hill is only a small part of a large question, and the memorialists are quite justified in saying that "such dismissals are likely to affect adversely the cause of scientific teaching in the United Kingdom." An action of this kind by a Government department will not tend to raise the dignity of scientific teaching in the eyes of the general public, and unless England is to fall far behind other countries it is essential that due regard be paid to those fundamental subjects of science on which the welfare of the whole community depends.

All interested in English education, and we may add that their number now includes the more intelligent of our manufacturers, know full well that the rapid strides now being made by American and German engineers are due to a gradual perfecting of the welding of science to practice. In America, a four years' course, including both the science and art of engineering, is the rule in the engineering colleges. The engineering department of the University of Birmingham starts with a four years' course in which those subjects which have been summarily and, as we hold, unwisely, ejected from the Coopers Hill curriculum will hold a large place.

Lord George Hamilton now knows what the representatives of English science think of the proposals for which he is responsible. The opinion of the professional electrical engineers of this country will be gathered from the following comments upon the case, which appeared in last week's *Electrician*:—"The crucial question, therefore, is whether the proposed changes will enable the College to turn out better engineers. What, then, are these changes? They involve the abolition of the chairs of physics, chemistry, hydraulic engineering and mechanism, the assistant professorship of engineering, the lectureship in accounts, the demonstratorships in the mechanical laboratory and in physics, and the instructorship in electrical engineering. The selection is amazing! What sort of engineering college training can it be that can dispense with a teacher for any one of these subjects? And, considering that the supply of telegraph engineers has been one of the chief features of the College, how are we to regard patiently the abolition of the professorship of physics and the instructorship in electrical engineering? This is economy false to the core—so palpably absurd, indeed, that we doubt if economy is the real reason for these startling changes. Lord George Hamilton stated that in the revised curriculum 'electricity would be thoroughly taught,' as Sir William Preece had advised them that 'a demonstrator was capable of giving all the necessary instruction.' We entirely dissent from this view; with the rapid increase in the engineering applications of electricity, not less but *far more* instruction in electrical and allied subjects becomes increasingly necessary in any engineering college."

Of one thing we may rest assured. When the Indian engineers only know chemistry "to the extent required to enable the engineer to interpret results given by professional chemists," as quoted from the official documents by Lord Kelvin; and physics and electrical science as imparted by Sir William Preece's "demonstrator"; the reputation of a noble service, which has during the last quarter of a century achieved such admirable results, will soon be a thing of the past.

NOTES.

WE have received the following circular relative to the dismissals at Coopers Hill College. "In consequence of the unsatisfactory nature of Lord George Hamilton's reply to the deputation which waited upon him on Tuesday, February 12, to present the memorial relating to the dismissals at Coopers Hill, it has become necessary to take action in Parliament. It would be of great service if the signatories to the memorial would draw the attention of their local Member of Parliament to the action of the Secretary of State for India, and ask him to interest himself in the matter when it comes before the House. A copy of the memorial will be forwarded to any signatory on application to The Secretary, The Museums, Cambridge."

AN abstract of an interim report on yellow fever, by Dr. Durham and the late Dr. Myers, has been received by the Liverpool School of Tropical Medicine. The abstract mentions that a small bacillus has been found in the internal organs of those dead of yellow fever. From the fact that this bacillus has been found constantly and in apparently "pure cultures," it is concluded that there is good reason to suppose it to be the cause of the disease, but at the same time the need of more experimental work to establish the claim is recognised. Careful search was made for parasites of the nature of protozoa, but the observers conclude that yellow fever is not caused by that class of parasite.

IN connection with the subject of the foregoing note, it is of melancholy interest to refer to articles in the *Jornal do Commercio* of Para, on the subject of the death of Dr. W. Myers and of the illness of his colleague, Dr. H. Durham, who both contracted yellow fever in the pursuit of their dangerous duties whilst acting on the Yellow Fever Expedition of the Liverpool School of Tropical Medicine. The following is a translation of parts of the articles:—"January 18. Drs. Durham and Myers.—Lying at present in the hospital Domingos Freire are the illustrious English doctors who came here in commission on behalf of the Liverpool School of Tropical Medicine to study yellow fever. Daily exposed to infection from the terrible disease, the day before yesterday, after an autopsy at an early hour on a case of very acute form of yellow fever, they began to feel the first symptoms, and without loss of time entered the hospital. A clinical service was arranged, assisted by numerous colleagues of the illustrious men of science, under the direction of their medical assistant. We sincerely hope for the recovery of the distinguished doctors, who through their noble dedication to science have been rendering us such great services, their investigations having already achieved entirely new results from which we may be permitted to look for promising advantages for our country and for humanity at large." "January 22.—In the isolation hospital Domingos Freire succumbed most rapidly and unexpectedly the English bacteriologist Dr. W. Myers, who came to this capital solely for the study of the disease to which he has fallen a victim—yellow fever. Following on a prolonged autopsy, both Dr. Myers and his illustrious companion, Dr. Durham, fell ill themselves, the latter still being under the burden of the disease. Dr. Myers' death took place on the afternoon of the 20th, and the burial was carried out yesterday morning, the coffin being carried from the hospital to the cemetery of Tanta Isabel by Dr. Paes de Carvalho, Governor of the State of Para, and Drs. Francisco Miranda, Americo Campos, Pontes de Carvalho, Gonçalo Lagos and other gentlemen alternately. At the side of the grave the following doctors spoke:—Paes de Carvalho, who showed by the sadness of his expressions the deep grief which he felt, and Americo Campos, as representative of the Medico-Pharmaceutical Society of Para. There were present a large number of members of the English colony, all in deep mourning and visibly affected."

THE neglect of ethnography in Great Britain has often been pointed out in these columns. In his presidential address to the Anthropological Institute on February 4, Mr. C. H. Read showed that not only is our country far behind other nations in respect to provision for teaching the subject, but also in ethnographical collections and accommodation for them. Germany, with colonial possessions infinitesimal in extent compared with those of England, has completely distanced us in this respect; the British Museum collections from British possessions being inferior to those of the Berlin Museum, which has exhibits seven times as numerous as those in the British Museum, and this disproportion is rapidly increasing. After the Benin expedition we allowed ourselves to be outbid in the purchase of specimens, and Mr. Read said that attention has in Germany been officially called to the fact that England seems to be too poor to be able to compete effectively for objects that are indispensable for her ethnographical collections. Most people will agree with Mr. Read that this state of things is a national disgrace, and shows a neglect of scientific interests as astounding to thoughtful minds as it is deplorable. In the matter of ethnographical material, we are apparently becoming renowned as the nation of lost opportunities. Can nothing be done to stimulate national interest in the collection of objects and conservation of knowledge fast disappearing before the advance of civilisation?

MR. VAUGHAN CORNISH, whose name is closely associated with the wave-like forms assumed by drifted materials, is now engaged on the Canadian prairies photographing and studying the forms assumed by drifting snow. Thanks to the liberality of the Canadian Pacific Railway Company and the interest evinced in the investigation by Sir William van Horne, Mr. Cornish writes that his work proceeds satisfactorily, and enough has already been done to justify the expedition.

THE last mail from Japan brings news that Mr. A. Imamura has been nominated assistant professor of seismology at the Imperial University of Tokyo, where he will work with Dr. F. Ōmori at the Seismological Institute. In addition to this Institute, there is in Tokyo a Seismological Investigation Committee, which has already published thirty-two volumes relating to its work, and also, at the Central Meteorological Observatory, a department which receives and analyses the registers relating to earthquakes observed at about one thousand co-operating stations distributed throughout the Empire.

THE next congress of the South-eastern Union of Scientific Societies will be held at Haslemere on June 6–8, under the presidency of Mr. G. A. Boulenger, F.R.S.

THE inaugural meeting of the Birmingham local section of the Institution of Electrical Engineers, which was to have been held on January 23, has now been fixed for Wednesday, February 27, in the University Buildings. Dr. Oliver Lodge, chairman of the section, will deliver an inaugural address, and the president of the Institution, Prof. J. Perry, F.R.S., will be present.

IT is announced in the *British Medical Journal* that an Italian Society of Biology has recently been founded on the initiative of many distinguished naturalists. The first meeting of the society will probably be held in Rome during the coming Eastertide. The object of the society is to promote the study of the biological sciences and everything relating to the advancement and teaching of these. The society will publish a bulletin giving an account of its proceedings.

ON Saturday next, February 23, Lord Rayleigh will deliver the first of a course of six lectures at the Royal Institution on sound and vibrations. On Tuesday, February 26, Dr. Allan Macfadyen will begin a course of five lectures on the cell as the unit of life, and on Thursday, February 28, Prof. Percy Gardner will deliver the first of a course of three lectures on Greek and Roman portrait sculpture. The Friday evening discourse on February 22 will be delivered by Sir William Roberts-Austen, K.C.B. His subject will be "Metals as Fuel."

THE Paris correspondent of the *Chemist and Druggist* states that M. Berthelot, one of the permanent secretaries of the Paris Academy of Sciences, is taking steps to carry out a resolution of that body to distribute annually a gold medal in memory of Lavoisier. M. Paulin Tasset, the engraver, is preparing the die of the medal, and has taken as a model a medallion of the great chemist in profile by David d'Angers. The inscription will be of the simplest nature. The name "Laurent Lavoisier" will appear under the profile, and on the back of the medal the words "Institut de France, Académie des Sciences, Medaille Lavoisier." The medal is likely to become greatly prized by chemists, and will be given for distinguished chemical research. It will be awarded for the first time this year by the Academy of Sciences, and its annual distribution is assured by a balance remaining over from the subscription for the monument, which was unveiled last summer behind the Madeleine Church, Paris.

THE anniversary meeting of the Geological Society was held on Friday, February 15. The officers were appointed as follows:—President: Mr. J. J. H. Teall, F.R.S. Vice-presi-

dents: Mr. J. E. Marr, F.R.S., Mr. H. W. Monckton, Prof. H. G. Seeley, F.R.S. and Mr. W. Whitaker, F.R.S. Secretaries: Mr. R. S. Herries and Prof. W. W. Watts. Foreign Secretary: Sir John Evans, K.C.B., and Treasurer: Dr. W. T. Blanford, F.R.S. The following awards of medals and funds were made:—The Wollaston Medal to Dr. Charles Barrois, of Lille, the Murchison Medal to Mr. A. J. Jukes-Browne, of Torquay, the Lyell Medal to Dr. R. H. Traquair, of Edinburgh, and the Bigsby Medal to Mr. G. W. Lamplugh, of the Geological Survey. The Wollaston Fund to Mr. A. W. Rowe, the Murchison Fund to Mr. T. S. Hall, of Melbourne, and the Lyell Fund to Dr. J. W. Evans and Mr. A. McHenry. The president delivered his anniversary address, which dealt chiefly with the evolution of ideas during the nineteenth century as to the genesis and classification of igneous rocks.

DURING the last fortnight an interesting series of letters on the audibility of the minute-guns at Spithead has appeared in the *Standard*, and several correspondents refer to other instances of the reports of guns being heard at great distances. The firing at Waterloo is said to have been heard at Heathfield (Sussex), as well as at Sandgate, Hythe and Ripple Court (between Dover and Deal), at Sandgate very heavy firing being heard throughout the day to the eastward. Heathfield is about 184 miles from Waterloo, Sandgate 144, Hythe 147 and Ripple Court 135 miles. Accounts are also quoted from Pepys' Diary on the sounds of the battle of Solebay being heard in London (about 100 miles), and, from the *Gentleman's Magazine*, of almost incessant heavy firing from Tournay being audible at Brean, Waltham, Brabourne and on other high lands in Kent (about 110 miles), and from the bombardment of Valenciennes at Dover (about 110 miles).

WE have received from Messrs. Lever Bros., Ltd., a translation of a report (which appeared in the *Strassburger Post*) of a lecture on wireless telegraphy, delivered by Prof. Braun at the Institution of Physics of the Emperor William University. Prof. Braun, after giving a short account of the history of the subject, proceeded to describe a system of wireless telegraphy which he had himself worked out. Instead of having a spark gap in the vertical wire, this wire is coiled at its lower end and oscillations are set up in it by induction from another coil containing the spark gap in which the oscillatory discharge takes place. This method, the lecturer claimed, is in many ways superior to that adopted by Marconi, and enables messages to be sent with more certainty and to a greater distance. The results of experiments that had been made were quoted, in which messages were transmitted a distance of about seventy-five miles, using masts ninety feet high at each end. Experiments on the Marconi system are compared with these, in which the results are certainly not so good as those obtained by Prof. Braun. We may, however, call attention to the announcement made by Prof. Fleming to the Liverpool Chamber of Commerce last week (p. 381) that Mr. Marconi had succeeded in transmitting messages a distance of 200 miles, and that messages could be sent simultaneously in both directions, and two or more could be received at once at each station. These results are extremely good, especially as they show that the difficulties of interference of one message with another have been partially, if not wholly, got over. We do not learn from the report of Prof. Braun's lecture whether he has succeeded in avoiding these difficulties in like manner.

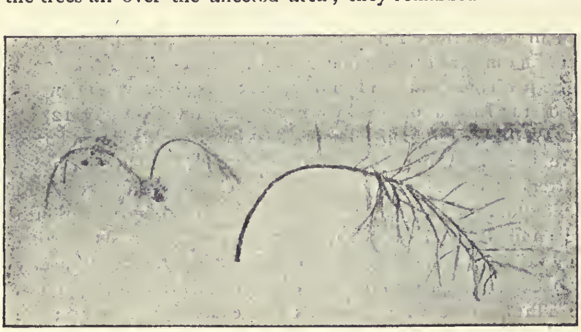
THE Government of New South Wales knows how to appreciate scientific information, and use it for the good of the Colony better than some Governments nearer home. A number of excellent pamphlets on the natural resources and industries in New South Wales have been prepared by Mr. T. A. Coghlan, Government Statistician, and distributed by the Agent-General for the Colony. A pamphlet on the timber resources shows that few countries have such a wealth of timber as New South Wales. Its woods are as varied as they are valuable, ranging from the ironbarks, unsurpassed for work requiring hardness and durability, to the kinds suitable for the most delicate specimens of the cabinet-maker's art. Forestry is, however, as yet only in its initial stages in New South Wales, though it is hoped that a School of Forestry will be established in the Colony before long. The importance attached to the diffusion of knowledge of agriculture is evidenced by the existence of a special Department of Agriculture. The central establishment possesses an experimental farm having a total area of 3430 acres, in addition to which there are several other large experimental farms and plantation trial stations. The agricultural position and outlook of the Colony are described in a separate pamphlet. Another pamphlet, on the climate of New South Wales, contains a large map of Europe having upon it the names of towns in the Colony placed beside European towns of corresponding mean temperature. Bourke, for instance, is placed by the side of Messina, Bathurst with Bordeaux, Cooma with Ventnor, and Kiandra with Edinburgh. Two other pamphlets deal respectively with the fauna and the mining industry of New South Wales. The whole series is commendable, and New South Wales is certainly to be congratulated upon the publication of so much valuable information concerning its resources and progress.

THE Nilgiri Railway is notable as being the first Abt-rack railway constructed in India, and, at present, the longest of its class in the world. It is, moreover, the first for which all the plant and material was manufactured in England. An account of the permanent way and rolling stock was given at the meeting of the Institution of Civil Engineers, on February 12, by Mr. W. J. Weightman. The railway was chiefly designed to serve the important towns of Ootacamund, the summer headquarters of the Madras Government, Coonoor, Kotageri and Wellington, the latter being the military sanatorium for South India and Burmah. It is 16¾ miles long, and from its starting point at Mettapollium on the Madras Railway, ascends nearly 5000 feet to the plateau on the Nilgiri Hills. The first 4¾ miles are adhesion-line with gradients not exceeding 1 in 40; the remaining 12 miles are built on the Abt-rack system, and have a ruling gradient of 1 in 12½. The formation-width is everywhere 16 feet, and as the rainfall is frequently 6 inches in as many hours, the greatest possible care has had to be taken to see that it is effectually drained. The locomotives are of the type known as "combined" Abt engines, that is, they can run either on rack or on ordinary line. Before the line was opened for traffic a series of brake experiments was made with a fully loaded train of 100 tons gross weight. With an ascending train at speeds of 6, 8 and 10 miles per hour on a 1 in 12½ gradient, stops were made in 24, 36 and 60 feet respectively; with a descending train at various speeds ranging from 4 to 12 miles per hour, relative stops were made in 54 feet, increasing to 425 feet.

A NUMBER of designs of flying machines have recently appeared in the illustrated papers. The *Graphic* for January 12 contains a figure of a kind of combination of ice boat and flying machine, attributed to an Austrian engineer named Kress. The arrangement of the aerocurves one behind the other would appear, according to Chanute's experiments, to detract from the lifting power of the hind ones. In the *Black and White Budget* for January 26 occurs the figure of a so-called "auto aviator," due to M. Firman Boussan. It is said to be surmounted by a vertical oblong balloon, thus resembling Dr. Danilewsky's balloon, to be provided with curved wings and propellers, and to be provided with wheels by which it can run

on the roads. Mr. G. L. O. Davidson's name has also recently figured in several papers in connection with the problem of artificial flight, and illustrations of one of his models appear in the *Scientific American* for February 2. The model in question is a bird-shaped glider, the tail of which has movable parts provided with automatic mechanism for regulating the balance and stability. It appears to have glided satisfactorily, but we do not gather from the journal in question that Mr. Davidson has himself performed glides through the air or experimented with motor-driven models. M. Santos Dumont has been experimenting with a motor-propelled balloon, weighing altogether not more than 250 pounds; but the only performance of which we have read consisted in the maintenance of a relative velocity of seven miles an hour for half a minute.

DURING a severe sleet-storm over a large tract of the northern United States, including Missouri, the water froze as it fell, forming such a heavy coating of ice upon the trees that many of them were bent to the ground by the load, as shown in the accompanying illustration from a paper by Dr. H. von Schrenk, in the *Transactions* of the Academy of Science of St. Louis. The tree in the foreground is a soft maple (*Acer dasycarpum*), likewise the row of trees of which it is one. The trees at the left are birches (*Betula alba*). The tops of the maples scraped on the snow of the street, and is was impossible for one person to lift the top of a tree, much less to restore it to its original position. These trees are good instances of the appearance ot the trees all over the affected area; they remained in the bent



position until the ice melted a week later, when the maples returned nearly to their original position and the birches stood quite upright as they were before the storm. Dr. Schrenk weighed about two hundred branches, taken from various trees, and he found that the ice-coated branches of the maples were nearly ten times heavier than the same branches without the layer of frozen water upon it. When the branches bore icicles the ratio was much greater, in many cases the weight being about thirty times greater than that of the branches without ice.

DR. E. LEYST has published in the *Bulletin* of the Imperial Society of Naturalists of Moscow an elaborate discussion of the daily range of barometric pressure at that place deduced from hourly observations, and has compared the results with those obtained from earlier observations and with observations made at St. Petersburg. The values of the harmonic analysis coincide generally with those deduced in the laborious discussions of Dr. Buchan and Dr. Hann. One of the important points of the discussion is the conclusion that the daily range at Moscow appears to have undergone a secular change in so far that the extremes of the daily curve occur earlier than was the case some thirty or thirty-five years ago.

THE vitality of certain micro-organisms, both pathogenic and otherwise, in milk under various conditions, forms the subject of an elaborate memoir by Messrs. F. Valagussa and C. Ortona, of the Hygienic Institute of the University of Rome, published in the *Annali d'Igiene Sperimentale.* The action of sunlight on bacteria in milk was investigated, and, as was only to be expected, in consequence of the opacity of the liquid no deleterious effect was detected, except in the case of those varieties which live on the surface of liquids and were, therefore, not shielded from the bactericidal action of sunshine. Another point of interest investigated was the effect of its inoculation into milk upon the elaboration of toxins by the diphtheria bacillus. It was found that although this bacillus does produce toxin when growing in milk, its strength is less than when grown in other culture-media; moreover, a marked increase in the strength of the toxin was noted when the cultivations were kept in a cool cellar instead of at the ordinary temperature of the laboratory. The exact thermal death-point of the tubercle bacillus in milk was also reinvestigated, this being a matter on which many different opinions are held. The authors state that exposure to a temperature of 60°, 70° and 80° C. is insufficient to guarantee the destruction of this bacillus in milk. Milk freshly drawn from the cow, with precautions ensuring its sterility, was found to afford a better culture material for bacteria than after it had been artificially sterilised by heating to 100° C. The paper is rendered of additional value by the very carefully compiled bibliography of the existing literature on the subject which is appended, and which makes it of special use to all interested in this section of dairy-bacteriology.

A PAPER on hermit-crabs allied to *Pagurus bernhardus*, by Mr. J. E. Benedict, is published in vol. xxiii. (pp. 451–466) of the *Proceedings* of the U.S. Museum, and is noteworthy on account of the excellence of the illustrations. Many of the forms described are closely related, but, in the absence of intergradation, they are classed as species rather than races.

Bulletin No. 14 of the Biological Division of the U.S. Department of Agriculture is devoted to a digest of the laws regulating the sale and transport of game in the different States of the union, the authors being Messrs. T. S. Palmer and H. W. Olds. All the States, it appears, are now fully convinced that unless stringent regulations are put in force the game animals and birds of America will ere long disappear for ever. It is satisfactory to learn that every State has now established laws bearing upon the preservation of game, although more general harmony between them might be advantageous. In their preface the authors state that an Act of Congress passed in May last supplements previous laws by prohibiting the shipment from one State to another of birds killed in violation of local laws, and by subjecting birds brought into any State to the regulations affecting native-raised specimens. The need of a compilation epitomising and contrasting the various laws and regulations has been much felt, and this want the present pamphlet endeavours to supply.

THE first three numbers of the new volume of *Die Natur* contain a full report of a lecture delivered in November last before the Verein zur Verbreitung naturwissentschaftlicher Kenntnisse in Vienna, by Prof. F. Toula, on the geological history of the Black Sea. The succession of events, beginning doubtfully in the lower or middle Oligocene, and with certainty in the uppermost Oligocene, is traced through nine distinct stages. The paper forms a most useful summary of recent research over an area including much of the eastern Mediterranean, and extending northward and eastward into Russia and Siberia; a considerable proportion of the work, especially that of Russian geologists and hydrographers, being not easily accessible.

ACCORDING to the *American Museum Journal* for December the search for fossil vertebrate remains in the far West is being prosecuted with as much activity as ever. Fourteen large cases of

mammalian remains from the Upper Tertiary of Texas, and several truck-loads of dinosaurian bones from the Jurassic of Wyoming and the Cretaceous of Dakota have reached the Museum as the result of last season's work. The dinosaurian remains include the skeletons of one large carnivorous form and of another more nearly allied to the iguanodon. In the same journal will be found an account of the collections in the geological department of the Museum and the manner in which they were acquired. The first important acquisition was the Holmes collection from the Tertiary of South Carolina; this was followed, in 1875, by the James Hall collection, which at once placed the Museum in the foremost position among American institutions in regard to Palæozoic fossils.

PROF. PENCK contributes a valuable paper to the *Zeitschrift* of the Berlin Gesellschaft für Erdkunde, on the glacial phenomena of Australia. The evidences of glacial action in different parts of Australia during permo-carboniferous times are discussed in detail, and brought into relation with traces of simultaneous action in India and South Africa; and it is shown that, apart from other difficulties, the hypothesis of a shifting of the South Pole to a central point (on the tropic of Capricorn in long. 86° E.) does not satisfactorily account for the geological facts. It is next pointed out that the appearances ascribed to ice action present in each case certain features not characteristic of ordinary glacial deposits—the deposits are stratified, and the pebbles are facetted in the manner first described by Wynne. Further, the Gondwána beds, always closely associated with these boulder deposits, have lately been found in the Argentine Republic. Prof. Penck compares the bedding and facetting with conditions induced by pressure observed in the Nagelfluh and in certain localities near Vienna, and concludes that while many indications certainly point to glacial action, these special points must be fully investigated before the formidable problem of accounting for the existence of glacial conditions over such an enormous area can be attacked. The second part of the paper summarises present knowledge of the quaternary glacial, or glacier, period in Australia and New Zealand, and compares the probable elevation of the snow-line in Australia and western Europe in quaternary and modern times.

MESSRS. J. J. GRIFFIN AND SONS have just introduced a new form of balance which should find a place on many lecture tables. The instrument is large enough to be seen clearly by a large class, and it can be manipulated by the lecturer without standing in front of it. The sensitiveness, rate of swing, length of arm and other characteristics can be altered so as to illustrate the principles of construction of a balance.

A PAPER by Messrs. K. A. Hoffman and E. Strauss on "radioactive lead" appears in the current number of the *Berichte*. This material is extracted from various minerals such as pitchblende, cleveite, broggerite, copperuranite, samarskite and euxenite, and resembles lead in being precipitated from its acid solution by sulphuretted hydrogen, in forming a sulphate insoluble in dilute sulphuric acid, and in having a yellow iodide. It differs from lead in the fact that it acts upon a photographic plate in the dark; it possesses a characteristic violet line in its spark spectrum, and its equivalent is markedly different, being 65·05 as against 51·7 for lead. The authors regard their results as being due to the presence of an element of an atomic weight of over 260, probably either divalent or tetravalent.

IN a recent contribution to the *Proceedings* of the American Academy of Arts and Sciences, Prof. Richards, of Harvard, expresses the opinion that the formal sanction of an international table of atomic weights is only a matter of a short time. The opinion elicited by the Commission of the German Chemical Society is overwhelmingly in favour of $O=16·00$ $(H=1·01)$ as against $H=1$ $(O=15·88)$, though some eminent authorities would adhere to the old standard. The second question put by the German Commission, as to whether the last figure set down in an atomic weight should be correct to within half a unit, is also answered in the affirmative by a large majority. From this consensus of opinion Prof. Richards is a dissentient, and he explains his position by reference to the case of nitrogen. The International Committee constituted through the German Chemical Society appears already to have made its decision, for in the first number of the *Berichte* for the present year there are inserted two tables of atomic weights, one of which is headed "Internationale Atomgewichte." In this the basis is $O = 16·00(H = 1·008)$, and the numbers given are accurate to one unit in the last place. The second table issued with the *Berichte* is of "Didaktische Atomgewichte" to the basis $H = 1·00(O = 15·88)$. It is obviously intended to meet the objections of teachers who foresaw difficulties in having to explain the use of 16 as the basis of a numerical system for atomic weights and densities. Opinions will differ as to the wisdom of having two tables current, but in any case they need not both be adopted by the same person. It would be hard for a teacher to have to remember that in the class-room S was 31·83, whilst in the laboratory it was 32·06. It is probable that most didactic requirements will be satisfied with $S = 32$.

THE additions to the Zoological Society's Gardens during the past week include a Common Guinea Fowl (*Numida meleagris*) from Morocco, presented by Mr. G. E. Veroutsos; fourteen Tree Frogs (*Hyla*, sp. inc.) from Barbadoes, a Capuchin (*Cebus*, sp. inc.) from South America, a Black-handed Spider Monkey (*Ateles geoffroyi*) from Central America, two Blood-rumped Parrakeets (*Psephotus hoematonotus*) from Australia, deposited; an August Amazon (*Chrysotis augusta*) from Dominica, four Banded Grass Finches (*Poëphila cincta*) from Queensland, two Arizona Heloderms (*Heloderma suspectum*) from Arizona, U.S.A., purchased.

OUR ASTRONOMICAL COLUMN.

REDUCTION OF OBSERVATIONS OF EROS.—In anticipation of the conclusion of the work on the planet Eros during the recent opposition, Prof. G. C. Comstock, of Washburn Observatory, U.S.A., contributes a note to the *Astronomical Journal*, No. 490, on the limits available in the necessary reductions. The question of reducing micrometer measures depends on the degree of accuracy with which it may be assumed that the mean of a number of settings represents the positions of the planet and comparison stars at the mean of the observed times. The problem is discussed with respect to three independent sources of changes in the observed coordinates.

(*a*) *Geocentric motion.*—General result is that if a set of measures does not extend over a period greater than one hour, the planet's motion may be treated as uniform, with a probable error of $\pm 0''·01$.

(*b*) *Parallax*, which changes with the observer owing to the diurnal motion. In this case the interval allowable is less than half an hour.

(*c*) *Differential refraction*, varying with the time of observation. For this element a table is given showing the correction introduced for varying zenith-distances.

CONSTANT OF ABERRATION.—The results of zenith-telescope observations of latitude at the Flower Observatory, University of Pennsylvania, are given by Mr. C. L. Doolittle in the *Astronomical Journal* (No. 490).

The correction to Struve's aberration constant was determined from these observations and applied to the final reductions. The following values of the constant have hitherto been derived:—

1892–1893	...	$20''·552$	...	at Bethlehem.
1894–1895	...	20·537	...	,, ,,

HARVARD COLLEGE OBSERVATORY.

THE fifty-fifth annual report of the work done at the Astronomical Observatory of Harvard College during the year ending September 30, 1900, has recently been circulated by the Director, Prof. E. C. Pickering, and is here summarised.

Observatory Instruments: *East Equatorial.*—The observations with this instrument were made by Prof. O. C. Wendell; during the year 24,000 photometric light-comparisons were made, principally with the achromatic prism polarising photometer. Over 15,000 of these were series of measures of twenty variables.

This instrument, with a second photometer adapted to stars nearer together, has been used for determination of the following:—

	Comparisons.		Comparisons.
o Ceti	1792	β Lyræ... ...	848
U Camelopardali.	160	Nova Aurigæ ...	96

and also in the photometric measurement of Jupiter's satellites while undergoing eclipse, eighteen eclipses having been observed; the satellites of Saturn, Japetus and Titan; the light of the planet Eros (224 settings), and in addition the systematic photometric observations of variable stars of long period have been continued.

Meridian Circle.—The ruled glass plate with which former determinations have been made for the last ten years has been replaced by spider lines, and the declination micrometer employed in conjunction for the first time. From the new observations a comparison is to be made between the accuracy obtainable by the two methods. The work of the instrument has been mainly confined to determinations of clock error and instrumental constants. The reduction of the observations made by the late Prof. Rogers from 1879–1883 is being continued.

12-inch Meridian Photometer.—With this instrument 79,024 settings were made by the Director on 140 nights. The first large work, comprising the observation of all the stars contained in the Durchmusterung, in zones 10′ wide and 10° apart, is now practically completed; the total number of stars is 9233, 6195 of which are fainter than the ninth magnitude. Good progress has been made with the reductions.

Meridian Photometer.—The observations of the stars south of declination −30°, of magnitude 7·0 and brighter, were completed early in December at Arequipa. Forty-four series were taken, involving 13,244 settings. The instrument was then sent to Cambridge, mounted, and electric light substituted for gas. A catalogue of standard stars, one in each 10° square, has now been prepared, and 16 series, including 6424 settings, have been made by Prof. Bailey.

Henry Draper Memorial.—Six hundred and eighty-nine photographs have been obtained with the 11-inch Draper telescope, and 2187 with the 8-inch instrument. The examination, by Mrs. Fleming, of the spectra on these plates and on those taken with the Bruce and Bache telescopes has led to the discovery of fourteen new variable stars, ten of which contained bright hydrogen lines in their spectra, and six are gaseous nebulæ. Eight variables have also been discovered in other ways. A new star in Aquila was found from examination of photographs, making the sixth object of this class detected in this manner.

In the study of the spectra of bright southern stars, it has been found that Hβ is bright in A.G.C. 8991, and variable in the two stars A.G.C. 19737 (η Centauri), and A.G.C. 20,878 (κ^2 Apodis).

Experiments are in progress for determining the photographic magnitudes of stars by the measurement of images out of focus, whereby a comparison is made of *surfaces* instead of *points*. It is found that stars can be measured in this way at the rate of five a minute, with a probable error of a tenth of a magnitude. Some 14,000 measures have been made in this way. For special purposes, charts are now being regularly taken with the 8-inch and 11-inch Draper telescopes, without following, by varying the rate of the clock and the position of the polar axis. A small telescope is rigidly attached to the base of the 11-inch telescope and directed toward two distant scales placed at right angles to each other, thereby permitting the axis to be set in any desired position rapidly and accurately. A photograph of the planet Eros was obtained in this manner on July 28, 1900, in which the image was sensibly round, although the exposure lasted 153 minutes.

Photographs of star occultations and eclipses of Jupiter's satellites have been obtained on several occasions.

Boyden Department.—As the sky was so clear at Arequipa during the latter part of 1899, it was unnecessary to remove the meridian photometer to the Desert of Atacama, Chile, as had been anticipated. Great delay has been experienced in the transmission of the plates to and from Peru, partly due to the quarantine consequent on the prevalence of fever along the west coast. The number of photographs taken with the 13-inch Boyden telescope is 201, and with the 8-inch Bache 2054.

Three hundred and fifty-eight visual observations of 48 southern variables have been made by Argelander's method. Systematic examination of all the stars south of declination −30°, between the magnitudes 6·3 and 7·0, inclusive, for the detection of new double stars, has been continued; 541 stars have thus been examined, leaving a further 450 requiring observation.

Meteorological Observations.—Observing stations have been maintained during the year at eight localities having altitudes varying from 100 to 19,200 feet; but great difficulty has been experienced at the lofty mountain stations.

These observations have now been continued for eight or nine years; taking into consideration, however, the striking uniformity of conditions which prevail in different years in this region, it is probable that additional observations would not greatly increase knowledge, and it has therefore been decided to suspend the meteorological observations of all the stations, except those at Arequipa. This seems to be a great pity, for nine years is a very short period when meteorological data are in question, and especially when the altitudes of the stations are so different.

The Bruce Photographic Telescope.—Seven hundred and sixty plates have been taken with this instrument during the year. From 319 of these 198 new faint nebulæ have already been detected. On these plates thus examined have also been found 92 asteroid trails and 2 meteor trails. In the spring of 1900 successful photographs of Eros were obtained by a special method when the object was too faint for ordinary procedures. The photographic plate was moved during exposure at the rate calculated for the motion of Eros relative to the diurnal motion. Three good plates were thus obtained on April 28, 30, 31, 1900.

A long series of photographs of Saturn was taken, to determine, if possible, the orbit of the satellite Phœbe. From an examination in Arequipa the existence of this object has not been confirmed; a careful examination will again be made on the arrival of the plates at Cambridge.

Blue Hill Observatory.—The chief work here has been the continuation of the exploration of the upper atmosphere by means of self-recording instruments carried by kites. The greatest height attained was 15,800 feet.

Miscellaneous.—(1) The scheme of distribution of important astronomical news is now greatly appreciated. Twenty bulletins have been issued during the year. These are sent gratuitously to all who desire them, and telegrams will be sent on payment of official fees.

(2) The long focus telescope obtained last year, with aperture of 12 inches and focal length of 136 inches, was lent to Prof. Langley, of the Smithsonian Institution, for photographing the corona during the eclipse of the sun in May 1900, the results being highly satisfactory.

(3) By the aid of an appropriation from the Rumford Fund of the American Academy, an important investigation has been started for the determination of standards for faint stellar magnitudes. For this work telescopes of 40, 36, 26, 15 and 12 inches aperture will be used, by the generous co-operation of the Yerkes, Lick and McCormick observatories with that of Harvard.

(4) A considerable number of photographs of the planet Eros have been taken, but as it is considered that the present opposition will not afford improved values of the solar parallax, it is doubtful if they will all be measured, unless the number obtained elsewhere be insufficient. Considerable care will, however, be taken in determining the variations of the light of the planet, both photographically and visually.

Establishment.—Prof. Pickering marks the completion of the work of the Observatory for the nineteenth century by giving a detailed account of the needs of the institution and the conditions of those portions of its work which are at present unfinished. The annual income is nearly 10,000*l.*, but this is required for current expenses. The estimated value of the buildings and instruments at Cambridge is about 15,000*l.*, and at Arequipa about 12,000*l.*

The main building at Cambridge is of wood, more than fifty years old, and the whole, including the invaluable astronomical library, is in constant danger of destruction by fire. The estimated cost of new modern buildings is about 20,000*l.* A large telescope for work at present entirely neglected in the southern hemisphere could also be obtained for a further 20,000*l.*

A long list of the principal unpublished investigations is given, most of which are ready for completion if means be forthcoming. These will occupy about twenty-eight volumes of the *Annals*, *i.e.* almost two-thirds as many as have already been published during the half-century of the existence of the Observatory.

SCIENCE IN TECHNICAL AND PREPARATORY SCHOOLS.[1]

EDUCATION is probably more discussed at the present time than ever it was before. It has become a subject for the newspapers, and to some extent for the political platform. It would seem there is now really a hope that the ordinary man of affairs will soon appreciate its importance. The advocates of education in science and technology have for years appreciated the reality and understood the reason of successful foreign competition, and now the lesson is being impressively driven home to every manufacturer by the tale of diminishing exports. Facts such as these give the recent report, made for the Department of Special Inquiries of the Board of Education by Mr. James Baker, on technical and commercial education in East Prussia, Poland, Galicia, Silesia and Bohemia, a very high value. Written as it is from the point of view of a skilled observer generally interested in the development of British industry and commerce, the report will receive more careful attention from the practical men engaged in manufacture than would the opinion of a mere student of pedagogics.

With the exception, perhaps, of the part of Russia he visited, though even there some progress is being made, Mr. Baker tells of the rapid advances he found have taken place everywhere in the development of technical and commercial education. And, what is of particular importance to us in this country, he demonstrates that the efficiency of any nation's supply of technical instruction in its various grades depends directly upon the satisfactoriness or otherwise of the national supply of primary and secondary education. It is that student alone who has received a thorough and suitable grounding in preliminary subjects who benefits by the specialised instruction of the trade school and technical college.

But this cause by itself is not sufficient to explain the high standard of foreign systems of technical education. In Prussian Poland and in parts of Austria the want of continuity between the work of the day schools and the higher technical studies of the trade schools has been abolished by legislation. In this country attendance at school during the years of apprenticeship is optional, with the result that even if the young workmen ever reach the classes specially designed to instruct in particular industries they have forgotten completely, by that time, their elementary knowledge; in the countries named, however, attendance at evening continuation or other schools is as compulsory as that at the ordinary day school. For instance, in describing the provisions for technical instruction at Posen, a town of 100,000 inhabitants in Prussian Poland, Mr. Baker writes of the Fortbildungsschules (continuation school, and the Gewerbschule or trade school: "This is for learners in all handicrafts. There is no payment, but the apprentices in all trades are compelled to attend this school under penalty of fine or even imprisonment. Lads commence here at fourteen and continue until eighteen, attending two afternoons a week and in the evenings. The employers are compelled to give their apprentices two afternoons a week, unless they are engaged upon work outside the town, when the lads are excused from attendance." Similarly, in connection with Trautenau, the Bohemian flax centre, with 16,000 inhabitants, we find: "Here all the apprentices must attend the trade continuation classes, which are held from six to eight in the evening and from eight to twelve a.m. on the Sunday. . . . In the Commercial Continuation School the same applies to business apprentices." And similar examples could be multiplied.

But it is impossible to manufacture, by any system of compulsion, enthusiastic students anxious to master everything known about the science of their trade and filled with a desire to improve upon the methods generally adopted. Continental authorities recognise this. It may be possible to raise the average ability of the workmen by enforced attendance at evening schools, but to discover the specially endowed craftsman who will repay all the trouble taken to place opportunities in his way, other plans are adopted. Here is one, expressed in Mr. Baker's words: "There is one great leverage the German schoolmaster possesses wherewith to lift his pupils into good work that an English teacher does not possess, and that is the fact, if a certain grade of work is passed, the student is freed from one or two years of military life, becomes a 'volunteer,' and only serves one year." But it is only in exceptional cases that this rule applies in Austrian towns, at all events in the lesser towns. Another means of attaining the same object is very common. In those schools which have not the right to exempt their pupils from one year of military service, an *Ausweis*, or leaving document, is employed, and on this is set forth the progress made, the behaviour and the diligence of the pupil, with a record of the attendance and a list of the subjects studied by the young man. This record has to be produced when the youth is called up for his time with the colours, and if the report is bad he may have to serve three years instead of two.

This subject of compulsory military service brings into high relief one great advantage the British workman has over his Continental contemporary in point of time. Mr. Baker writes eloquently in this connection: "In going through these technical schools I saw young men working at the most delicate handicrafts; they had just arrived at excellency; their skilled hands, guided by a highly cultured brain, were turning out work most delicately artistic; but they must lay down their tools and take up sword and rifle for two years, or three if in the cavalry or artillery; their hands must forego the exercise of their cunning, if they do not lose it altogether; . . . Herein is the Englishman's opportunity when he obtains the same advantages of education as the Austrian or German; he can at once leap ahead of his Continental competitor, for he gains these two years given up by the Continental to military service."

But perhaps the most remarkable characteristic of Austrian technical education is the extent to which decentralisation has been carried throughout the country. While making due provision for advanced work in a few large centres, the object of the authorities seems to be to bring suitable instruction in the technology of the particular industry of a district to the very doors of the workers. A notable instance of this, and it is typical, is the case of Turnau, or Turnov, the jewellers' town. It is a little place of 6500 inhabitants, whose chief industry is goldsmiths' work and the polishing and setting of jewels. Here has been established a Royal Imperial trade school for jewel cutting, polishing, engraving and setting in gold, but in addition to this technical institute there are four Volksschulen (primary schools), a Bürger school, and a continuation school in winter for handicraftsmen. The students of the Royal Imperial trade school come direct from the Volksschulen, beginning this special work at fourteen and remaining for four years. The tuition is free, but the lads receive no pay. The total number of pupils in the school is seventy-eight, and they are all being converted into cultured artisans. When they pass out of the school they are given a leaving certificate, which confers the full status of a workman and ensures treatment as an educated man for the holder.

The question naturally presents itself, What manner of men are in charge of institutions the object of which is to produce accomplished artisans who are also at the same time educated in a higher and more general sense? On this subject, too, the report under consideration supplies abundant information. In the description of the technical college at Prague a short life-sketch of Director Edward Cerny is given. He bears the title, by the way, of Royal and Imperial Councillor—a proof of the esteem in which men of science and educational leaders are held in Austria, where, as in Germany, such authorities are commonly nominated Privy Councillors, and receive titles and decorations. It is impossible in a short article to refer to all Director Cerny's qualifications; it must suffice to say that his case is quite general and that the common rule is to appoint

[1] Report on Technical and Commercial Education in East Prussia, Poland, Galicia, Silesia and Bohemia. By James Baker, 122 pp.
Board of Education Special Reports on Educational Subjects. Volume vi. Preparatory Schools for Boys: their Place in English Secondary Education. 531 pp.

"practical engineers or business men, thus bringing to bear on their teaching, not only the general education gained at school and their thorough knowledge of theoretical science, but also their practical experience of the workshop and business life."

These are but a few of the vital questions with which this valuable report is concerned. We heartily commend the volume to all who are interested in improving the home supply of technical education until it is not only on a level with that of Germany and Austria, but well in advance.

When we turn to the second of the reports, that concerned with the place in English secondary education of preparatory schools for boys, we are confronted with another stage in the preparation of the citizen for the duties of life. As every one knows, probably, the preparatory school undertakes the education, up to about fourteen, of the boy destined for our great public schools. Generally, after some five years at the public school, this fortunate son of well-to-do parents proceeds to either Oxford or Cambridge to continue his education. It is interesting to inquire as to the share science takes in the work of a preparatory school. It may be stated parenthetically that in a volume of 531 pp. only some sixteen pages are devoted to the teaching of mathematics and natural science together, though it is true nine of the sixteen are given to the latter.

It must be said at once that any science teaching at all in preparatory schools is the exception rather than the rule. To quote Mr. Archer Vassall, of Harrow, who deals with the subject in the official publication before us, "tentative efforts in scientific instruction have been made, and are still in progress at many of them"—and that is all that can be said. But there is nothing surprising about this. Since the sole function of the preparatory school is to prepare for the public school, those subjects only which are in demand in the second will be taught in the first, and, to quote Mr. Vassall again, "in public schools the teaching of science has only recently begun to take reasonable shape," a condition brought about by the regulations governing the award of University scholarships. So that to ensure an improved condition of things in the preparatory school men of science must bend their efforts towards securing reforms at Oxford and Cambridge.

Mr. Vassall's short article is chiefly concerned with a sketch of a suitable preparatory school course in natural science. In common with modern ideas he insists upon the need of individual practical work, and very properly urges that the study of science might well begin with what he calls "kindergarten physics." This mode of procedure has for some years been followed in higher grade boards schools, and in those other secondary schools which have adopted the syllabus of the Headmasters' Association. But we think Mr. Vassall is wrong in excluding chemistry from his preliminary course, for there are many excellent exercises which are in no way dangerous. Anyhow, a beginning has been made with science in preparatory schools, and if the masters will acquaint themselves with the results of experience in schools of other grades, we shall soon hear that science has gained for herself a more honourable place.

A. T. SIMMONS.

THE FIGURE OF THE EARTH.[1]

THE United States Coast and Geodetic Survey has just published a quarto volume containing an account of the transcontinental triangulations and measurements of an arc of the parallel in latitude 39°. It also has ready for publication the manuscript giving the result of an oblique arc in the eastern part of the United States. Both are contributions of great length and among the first of their kind in America.

Before entering upon the detail of the two arcs it may not be out of place to state that in order to obtain a measure of the dimensions of the earth, as represented by a spheroid, that is, by a surface generated by the rotation of an ellipse about its minor axis, it is essential that we should be in possession of at least two arcs or of an equivalent thereof. For combinations of two arcs of the meridian, their mean latitudes should differ widely; the same is true for the combination of two arcs of the parallel. We may also obtain an arc of the meridian with one of the parallel, but in every case the measures should be of considerable extent. Arcs of less than 5° (about 556 km., or 345 st. miles) would now be regarded as short ones. It has been stated that one of the arcs is an oblique arc, and as it possesses a great range of latitude and also of longitude and is supplied with a large number of astronomical measures, it is of itself sufficient for the deduction of values for the dimensions of the earth. Furthermore, it may be remarked that for any relatively small part of the earth's surface an osculating spheroid may be determined, as, for instance, was done for our oblique arc. Such a spheroid has the property that its surface is in best accord, as regards curvature, with the actual or physical one, the latter considered as a mathematical surface of equilibrium and generally known as geoid.

The definition of an osculating spheroid thus implies that the sum of the squares of the difference between the various astronomic and geodetic measures be a minimum. The mathematical treatment of the combination of the arc measures differs according to their nature, whether they are extended in a certain direction or whether large areas are covered, but in its generality it is necessarily laborious.

The salient points of the two arcs measured by the U. S. Coast and Geodetic Survey and the results reached may now be briefly stated. First, the arc of the parallel in latitude 39°.[1] It extends from Cape May, N.J., on the Atlantic coast, to Point Arena, Cal., on the Pacific coast, and ranges over 48° 46′ of longitude, with a linear development of about 4225 kilometres, or 2625 st. miles. The triangulation is supported by ten base lines with an aggregate length of 53½ st. miles, the longest or Yolo base being 10·9 miles in length, one half of these lines having a smaller probable error of measure than one part in a million. A characteristic of the triangulation is its rigidity imparted to it by quadrilaterals and other polygons. In crossing the Rocky Mountains, many of its sides exceed one hundred miles in length, and there is one side reaching to a length of 294 km., or 183 st. miles; the altitude of many of the stations is also considerable, reaching to 4300 metres, or 14 108 feet, in the case of Pike's Peak, and to 14,421 feet at Mount Elbert. All geometrical conditions subsisting in the triangulation are satisfied by adjustment, inclusive of the required accord of the base lines, so that the same length for any given line is found no matter from what line one may start. This involved much heavy work; for instance, the triangulation adjustment between the Salina and the El Paso base demanded the simultaneous solution of ninety-nine normal equations (with as many unknowns). In addition, the figures required the evolution of a correction to each of the two hundred and twenty-five observed directions.

Coming to the astronomical measures, we have distributed over or near the arc one hundred and nine latitude stations, occupied almost exclusively with zenith telescopes; there are, also, seventy-three azimuth stations, various methods having been used, and lastly we have twenty-nine telegraphically determined longitudes. These, of course, are of paramount importance for an arc of the parallel. There cannot be too many longitude stations in consequence of that great stumbling-block in geodesy, the local deflections of the vertical or plumb-line. These deflections of the zenith from a normal direction have been divided into two groups—those which are regional or manifest themselves with marked common features over thousands of square miles, and those which are quite local and greatly depend upon the surface features immediately surrounding them.

These deflections, even in level countries, average about 2·5″; but in mountainous regions this deflection is greatly surpassed. Thus we find for deviation of the plumb-line at Patmos Head station 12″ to the north, at Colorado Springs 25″ to the west, at Salt Lake City about 17″, and at Ogden about 15″ to the east, at Genoa Station, Nev., nearly 29″ to the west, the quantities depending to some extent on the spheroid of reference; but their amount and direction are obviously well accounted for by the position of known attracting masses. In connection with this, continental attraction may manifest itself and be recognised by the astronomical amplitude of the longitudes of extreme stations of a long arc being in excess of the corresponding geodetic amplitude. The matter cannot be further pursued here in detail, but it may suffice to state that the average curvature of the equipotential surface of the geoid along the parallel of 39°

[1] Abridged from a paper on recent contributions by the United States Coast and Geodetic Survey to our knowledge of the earth's shape and size, by Mr. C. A. Schott, in the *National Geographic Magazine*, New York.

[1] U. S. Coast and Geodetic Survey; H. S. Pritchett, Superintendent. The Transcontinental Triangulation and the American Arc of the Parallel. By C. A. Schott, Assistant, Coast and Geodetic Survey, Washington, D.C., 1900.

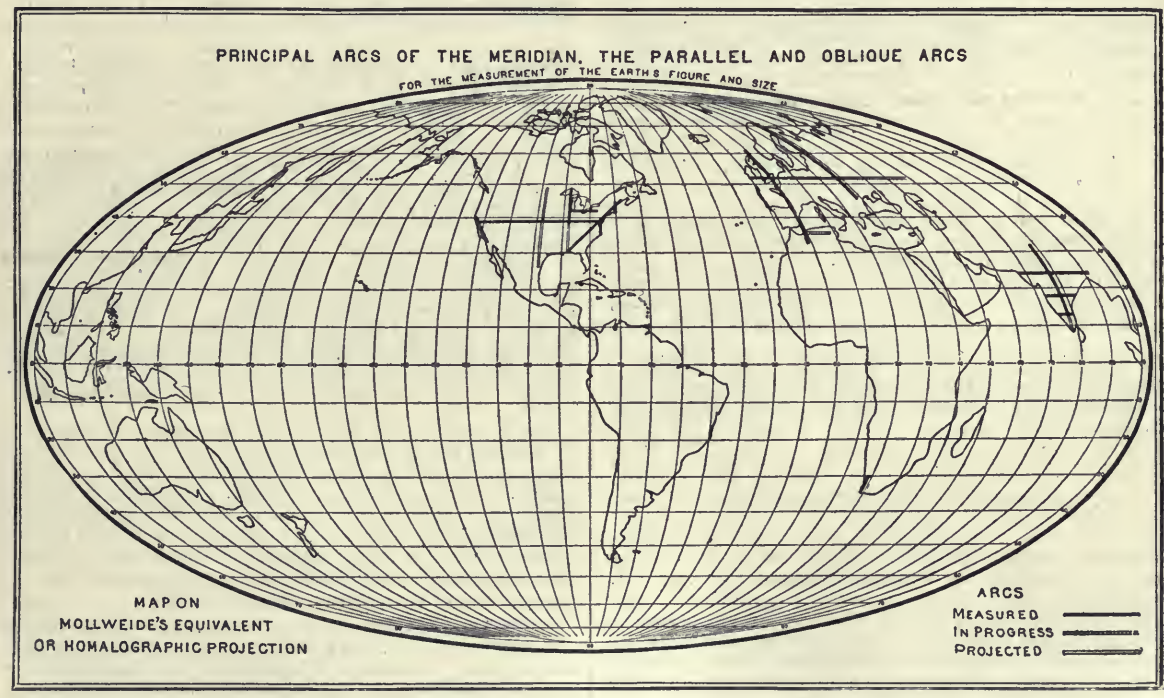
approaches for about four-sevenths of the arc from its eastern end closely to that of the Clarke spheroid; whereas, for the remaining three-sevenths, or for the region across the Rocky Mountains to the Pacific, the curvature comes more nearly to that of the Besselian spheroid. In the published paper two tables are given containing the results needed for combination with any other arc and, in conclusion, some preliminary rough combinations of American arcs are presented; all of which point to a reference spheroid of larger dimensions than those of the Besselian and are in favour of continuing the use of Clarke for reference.

The second arc under consideration extends from Calais, Me., in the north-east and opposite the Canadian boundary, to the Gulf of Mexico, and terminates at New Orleans, La. It is known as the Eastern Oblique Arc of the United States. Its length is 2612 km., or 1623 statute miles; its difference of latitude is 15° 1′, and of longitude 22° 47′. The general direction is therefore favourable, and the length ample to secure fair results for an osculating spheroid. In the main the triangulation follows the Appalachian chain of mountains; in Western North Carolina and Eastern Tennessee it bifurcates, leaving an oval space between the two branches. The length of sides depends upon six base lines, and in general the development is closely accommodated to the hypsometric and other natural conditions along the course. It includes among its stations the two highest points in the eastern part of the United States, viz. Mount Washington, N.H., rising to about 1920 metres, or 6300 feet, and Mount Mitchell, N.C., rising to about 2038 metres, or 6687 feet.

The adjustment of the whole triangulation is effected precisely as explained in the use of the arc of the parallel; the small reduction to the sea-level of the observed horizontal directions, on account of the altitudes sighted, was only applied when exceeding 0·05″. The principal labour of adjustment was demanded by the necessity of bringing into accord the measured lengths of the Fire Island, the Massachusetts and the Epping base lines, and fulfilling the geometrical conditions of the intervening net of triangles. This demanded the satisfying of fifty-seven conditions and involved the simultaneous solution of an equal number of normal equations and the working out of 131 corrections of observed directions. Of astronomical measures we have seventy-one latitute stations, seventeen longitude stations, and fifty-six azimuth stations, tolerably well distributed over the whole extent of the arc. The latitudes, as were those of the arc of parallel, were corrected for height of station or curvature of the vertical and for variation of pole according to Dr. Chandler's and Dr. Albrecht's researches. The same scrutiny as before had been extended to the deflections of the vertical, both regional and local. Partly on account of avoiding unnecessary labour, but principally on account of the crowding together of astronomical stations in certain very limited localities, and all of them, therefore, partaking of the deflections characteristic of this area, the total number of astronomical stations admitted into the final equations for the determination of the best spheroid were thirty-six for latitude, fourteen for longitude, and thirty-four for azimuth, or eighty-four conditions in all.

These eighty-four differences between the astronomical and geodetic results constitute the data needed for a new determination of a spheroid; next the functional relations between the positions of these stations upon the reference spheroid to the earth's equatorial radius and to the compression of the polar axis had to be established.

The final normal equations contain, therefore, four unknown quantities, viz. the correction to the meridional deflection of the vertical at the initial or reference station of the oblique arc; second, the corrections to the deflection of the vertical, in the plane of the prime vertical, at the same place; third, correction to the equatorial radius of the reference spheroid; and, last, the correction to its compression.



In the combination of conditional equations arising from observations of a different nature, the question of their relative weights must be considered. In the present case, four assumptions were made and the consequent normal equations solved, viz. for equal weights, for weights one-half, one-third and one-fourth to the azimuth equations, the latter being necessarily inferior to the equations derived from latitudes and longitudes. A comparison of these four results showed that it was of small consequence which of these hypotheses was finally adopted, since the corrections to the equatorial radius of the reference spheroid were practically the same for any of these hypotheses, and nearly the same could be said of the resulting compressions. The weight one-third to each of the azimuth equations was finally decided upon, and the resulting dimensions of an osculating spheroid were found to be:—Equatorial radius, 6,378,157 ± 90 metres; compression, 1/304·5 ± 1·9. The equatorial radius, therefore, differs but 49 metres from Clarke's value of 1866 adopted on the Survey, while the Besselian value is apparently too small by 809 metres. On the other hand, the compression or the ratio of the difference of the equatorial and polar semi-axes to the former is in favour

of Bessel's spheroid, of which the compression is 1/299·2; that is, one more closely approaching a sphere.

In the present state of our knowledge there is no reason to suppose that the curvature of the northern part of America differs any more from that of a general spheroid derived from arcs of all kinds so far measured than local ones in either hemisphere differ among themselves. A comparison of a number of such locally adopted spheroids will bring to evidence the local deformities in the shape of the earth's equilibrium surface and furnishes the geodesists endless material for the study of the earth's actual figure.

The manuscript concludes with a comparative table of the dimensions of several spheroids which of late have come more into prominence. It is as follows:—

Spheroid of	Equatorial radius, a, in metres.	Polar semi-axis, b, in metres.	$a-b$.	Compression $(a-b)/a$.
Bessel, 1841. From ten arcs of the meridian and total amplitude 50° 34′	6,377,397	6,356,079	21,318	1/299·15±3·15
Clarke, 1858. Special spheroid for surface of Great Britain and Ireland; range of latitude 12°, the same in longitude; seventy-five astronomic stations	6,378,494±90	6,355,746	22,748	1/280·4±8·3
Clarke, 1866. From five meridional arcs, of total amplitude 76° 35′	6,378,206	6,356,584	21,622	1/295·0
Clarke, 1880. From five meridional arcs and longitudinal measures, total amplitude 88° 59·8′ (equatorial degrees)	6,378,249	6,356,515	21,734	1/293·5
United States Coast and Geodetic Survey, 1900. Eastern oblique arc of the United States; total length, 23° 31′, and eighty-four astronomic stations	6,378,157±90	6,357,210	20,947	1/304·5±1·9
Harkness, 1891. From "The Solar Parallax and Related Constants," Washington, 1891, p. 138. From a variety of sources	6,377,972±125	6,356,727±99	21,245	1/300·2±3·0

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—A valuable collection of Greek papyri from Oxyrhyncus and the Fayûm has been presented to the University library by the Egypt Exploration Fund.

Dr. A. C. Haddon, F.R.S., University lecturer in ethnology, and professor of zoology in the Royal College of Science, Dublin, has been elected to a junior fellowship at Christ's College.

THE King's Speech to the Commons at the opening of Parliament on Thursday last contained the announcement that "Legislation will be proposed to you for the amendment of the law relating to education."

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, February 7.—"The Integration of the Equations of Propagation of Electric Waves." By A. E. H. Love, F.R.S.

The equations of propagation of electric waves, through a dielectric medium, involve two vector quantities, which may be taken to be the electric force and the magnetic force. Both the vectors are circuital; and the several components of them satisfy the partial differential equation of wave propagation, viz. $\ddot{\phi} = c^2\nabla^2\phi$, c being the velocity of radiation.

Owing to the circuital relations, certain known solutions of the partial differential equation of wave propagation are not available, for representing the components of the vectors. A very general system of *particular* solutions, which are available for this purpose, is obtained. These include solutions corresponding to two types of sources of electric radiation:—The sources of one type are similar to infinitesimal Hertzian vibrators, being related in the same way to an axis, but the dependence of the emitted radiation on time is arbitrary; the sources of the other type are obtained therefrom by interchanging the *rôles* of the electric and magnetic forces.

The general integrals of the equations would express the values of the vectors, at one place and time, in terms of their values, at other places and times. To find such integrals, we require (1) sets of particular solutions, which tend to become infinite, in definite ways, in the neighbourhood of chosen points; (2) a theorem of reciprocity, connecting the values, on any chosen surface, of two sets of solutions; (3) the limiting form, assumed by the theorem of reciprocity, when the solutions of one system have the assigned character of infinity at a given point. The solutions required for the first step are among those already found; the theorem of reciprocity is obtained by a modification of the process by which the fundamental equations can be deduced from the Action principle; and the limiting form of the theorem is found by adapting a process due to Kirchhoff. The result is that the radiation which arrives at a chosen point may be regarded as due to a distribution of imagined sources of radiation upon an arbitrary closed surface, separating the point from all the actual sources of radiation. The imagined sources are of the two types previously specified; and the directions of their axes, and the intensities of the radiation sent out from them, are determined simply and directly by the values, on the surface, of the vectors involved in the propagation of the waves.

The general theorem is applied to the problem of the passage of radiation through an aperture, and the result is utilised to determine the rate of decay of the vibrations of a condensing system. The example of a condenser, with concentric spherical conducting surfaces, the outer conducting sheet being perforated by a small circular aperture, is worked out in detail; and the results suggest that the maintenance of the vibrations depends on the screening action of the outer conductor rather than on the largeness of the capacity of the condenser.

Anthropological Institute, February 4.—Annual General Meeting.—Mr. C. H. Read, president, in the chair.—On a ballot the following were elected to office for the ensuing year:—President: Prof. A. C. Haddon, F.R.S. Vice-presidents: A. J. Evans, W. Gowland, Prof. G. B. Howes. Hon. Treasurer: A. L. Lewis. Hon. Secretary: J. L. Myres. Council: Sir T. H. Holdich, Sir C. E. Peek, Messrs. G. M. Atkinson, H. Balfour, W. Crooke, Prof. D. J. Cunningham, W. L. H. Duckworth, R. W. Felkin, H. O Forbes, J. G. Garson, E. S. Hartland, T. V. Holmes, E. F. im Thurn, A. Keith, R. B. Martin, M.P., R. H. Pye, E. G. Ravenstein, Prof. W. Ridgeway, W. H. R. Rivers and F. C. Shrubsall. After reading and discussion of the reports of the treasurer and council, the retiring president proceeded to give his address. After alluding to the death of Her Majesty Queen Victoria and paying a tribute to Lieut.-General Pitt-Rivers, an ex-president of the Institute, Prof. Max Müller, Miss Kingsley and other distinguished Fellows who had been removed by death, he went on to call attention to the progress made by anthropology, more especially in the British Empire, during the past year. A joint memorial of the Folk-lore Society and the Institute had been presented to the Government, urging the theoretical and practical importance of an inquiry into the status of native races in South Africa. In India, in combination with the census, a scheme for a partial ethnographical survey had been called into existence, over the working of which the Hon. H. H. Risley would preside. He hoped that in England we should soon have chairs of anthropology at all the important teaching

centres; Birmingham had a great opportunity of founding a professorship; at Cambridge, if a sum of 200*l.* or 300*l.* could be guaranteed for a few years, a chair could be established; this was an opportunity for an Englishman to emulate the good works of American millionaires in coming to the aid of science. Not only in respect of teaching, but also in respect of ethnographical collections and accommodation for them, was Great Britain far behind other nations. (See p. 402.)

Geological Society, Feb. 6.—Mr. J. J. H. Teall, F.R.S., president, in the chair.—On the structure and affinities of the Rhætic plant *Naiadita*, by Miss Igerna B. J. Sollas, Newnham College, Cambridge. (Communicated by Prof. W. J. Sollas, F.R.S.) This plant, the remains of which are found in Gloucestershire, was considered to be a monocotyledon by Buckman, but a moss by Starkie Gardner. Material supplied by Mr. Seward and Mr. Wickes has given the authoress ground for the belief that *Naiadita* is an aquatic lycopod, and that it is the earliest recorded example of a fossil member of the Lycopodiaceæ, resembling in proportions and outward morphology the existing representatives of the group.—On the origin of the Dunmail Raise (Lake District), by Richard D. Oldham. The conclusion arrived at is that the gap of the Dunmail Raise was formed by a river, which flowed across the hills from north to south and cut down its channel *pari passu* with the elevation of the hills. The final victory of upheaval over erosion, whereby this river was divided into two separate drainage-systems and the barrier of the Dunmail Raise upheaved, may have synchronised with a diversion of the head-waters and consequent diminution of volume and erosive power. It is pointed out that this explanation comes into conflict with previously published theories of the origin of the drainage-system of the Lake District, inasmuch as the elevation postulated seems too slow to be explicable by the intrusion of a laccolite; and that the existence of a large river crossing the area of upheaval, and the maintenance of its character as an antecedent river-valley for a long period, show that the surface was originally a peneplain of subaërial denudation, and not a plain of marine sedimentation or erosion. From this it follows that the course of the main drainage-valleys may not have been determined by the original uplift, but, with the exception of those which are old river-valleys, whose direction of flow has been reversed on the northern side of the uplift, may have been formed by the cutting-back by erosion into the rising mass of high ground—in other words, that the principal valleys of the Lake District may be subsequent, not consequent, in origin.

MANCHESTER.

Literary and Philosophical Society, February 5.—Prof. Horace Lamb, F.R.S., president, in the chair.—Mr. T. Thorp and Dr. C. H. Lees were nominated as auditors for the current year.—Prof. Flux referred to the records of a recent report on water, gas and electricity undertakings, so far as they showed the rate of return on the capital invested in each case. The rates were grouped most thickly about 3 to 3½ per cent. for each class of enterprise, more closely in the case of water and, in a less degree, of gas than in the case of electricity. The total number of undertakings contributing to the result named was 1351, and the lowness of the figure representing the most frequent rate seemed rather striking.—Mr. Thomas Thorp mentioned that he had made further progress with an instrument designed to yield a pure monochromatic image of the sun, and had been able to obtain results of an encouraging nature. He hoped to be able to perfect the instrument in a short time and to exhibit it before the Society.—Dr. George Wilson read a paper, prepared by Mr. H. Noble and himself, entitled "Note on the construction of entropy diagrams from steam-engine indicator diagrams," showing how the effect of the clearance steam may be taken account of in the ordinary pressure-volume curve, thus enabling trials of different engines to give directly comparable results.—Mr. C. E. Stromeyer read a paper on the representation on a conical mantle of the areas on a sphere, in which he showed that the representation of points on the surface of a sphere on an enveloping cone, the distance of corresponding points on sphere and cone from the vertex of the cone being equal, gives a map on the developed cone the areas on which are proportional to those on the sphere.—The president announced at the close of the meeting that April 22 had been provisionally fixed for the delivery of the postponed Wilde Lecture by Dr. Metchnikoff.

EDINBURGH.

Mathematical Society, February 8.—Note on the cooling of a sphere in a finite mass of well-stirred liquid, by Dr. Peddie.—Some inequalities relating to arithmetic, geometric and other algebraic means, by R. F. Muirhead.

PARIS.

Academy of Sciences, February 11.—M. Fouqué in the chair.—On the generation of the hydrocarbons by the metallic carbides, by M. Berthelot. From an examination of the thermochemical data concerning the metallic carbides, it is shown that the condition that an acetylide on treatment with water should give acetylene is that the difference between the heats of formation of the metallic hydrate and acetylide should be greater than 196·1 calories. This is the case with the carbides of the alkalies and the alkaline earths, but not for the acetylide of silver, and this latter compound is accordingly not decomposed by water. The cause of the production of a complicated gas mixture in some cases is also discussed from a thermochemical point of view.—Observations on the solutions of solid metals in mercury, and more generally in other fused metals, by M. Berthelot. It is pointed out that the use of the word solution to express the uniform distribution of a metal in mercury is not, strictly speaking, parallel to ordinary solution.—On precession, by M. O. Backlund. Correcting an error in a previous note.—On the specific heats of fluids, the elements of which are submitted to their mutual actions, by M. P. Duhem. It is shown that all the laws demonstrated in elementary thermodynamics for a fluid submitted to a normal and uniform pressure may be extended to a fluid the elements of which exercise any actions whatever upon each other, whether Newtonian or not.—On the photography of the solar corona in solar eclipses, by M. H. Deslandres. An account of the methods employed and the results obtained on the photography of the sun's corona during the solar eclipse of May 28, 1900.—On the theory of the satellites of Jupiter, by M. J. J. Landerer. A comparison of the results of observation with the theory of Souillart.—A new class of algebraic surfaces which admit of a continuous deformation and still remain algebraic, by M. D. Th. Egorov.—On certain transformations of Backlund, by M. Clairin.—On the theorem of Hugoniot and the theory of characteristic surfaces, by M. J. Coulon.—On a class of partial differential equations of the second order, by M. R. d'Adhémar.—On the linear partial differential forms of a system of simultaneous differential equations which are also the integrals of this system, by M. A. Buhl.—On circular arches, by M. Ribière.—On the diurnal variation of the magnetic declination, by M. Alfred Angot.—Calculation of the formula giving the law of the regular distribution of the horizontal component of the earth's magnetism in France on January 1, 1896, by M. E. Mathias.—An electric anemometer indicating at a distance, by M. Emmanuel Legrand. The motion of the vanes of the anemometer drives a small Gramme ring, the current from which is connected to a d'Arsonval galvanometer at a distance. The electromotive force produced is proportional to the velocity of rotation of the vane.—Telephonic communication by means of a wire stretched across the snow, by M. A. Ricco.—Remarks on the preceding communication, by M. Janssen.—The law of transparency of matter for the X-rays, by M. Louis Benoist. The specific opacity of a body to the X-rays is independent of its physical state, of the mode of atomic grouping and of the state of liberty or combination of the atoms. For X-rays sufficiently penetrating and homogeneous, the specific opacity of elements is a determinate and increasing function of the atomic weight, the two magnitudes being approximately proportional.—New researches on electric convection, by M. V. Crémieu. The author has repeated some of his original experiments with additional precautions, and considers it finally established that under the conditions of the experiments of Rowland and Himstedt electric convection produces no magnetic effect.—On musical impressions, by M. Firmin Larroque.—On the formation and decomposition of the acetals, by M. Marcel Delépine. The formation of acetals is a limited reaction, a state of equilibrium being set up between the alcohol, acetal, aldehyde and water. The results of experiments upon the limiting values of this reaction are given for methylal, dipropyl formal, erythrite diformal and mannite diformal.—On the elimination of methane from the atmosphere, by M. V. Urbain. Recent researches by MM. Muntz and Aubin and by M. Gautier on the amount of methane in the atmosphere, compared

with those of Boussingault, show that the proportion of this gas has not increased. Hence, like carbonic acid, it would appear to be eliminated in some way. By an extensive series of experiments, the author shows that this elimination is effected by plants.—Actions of the esters of the monobasic fatty acids upon the mixed organo-magnesium compounds, by M. V. Grignard. The use of magnesium has the advantage over the Wagner-Satzeff reaction not only in its simplicity and increased yield, but also in increased generality. Thus ethyl formate and magnesium ethyl bromide gives a 73 per cent. yield of diethylcarbinol; with isoamyl bromide of magnesium and ethyl formate the formate of diisoamylcarbinol is obtained. Diisobutylcarbinol can be prepared by the analogous reaction.—On the absorption of light by the indophenols, by MM. P. Bayrac and C. Camichel.—On the acid and alcoholic combinations of phenylcarbazide, or the urea of phenylhydrazine, by M. P. Cazeneuve.—Ketones from wood tar, by M. A. Behal. The ketone, dimethylcyclohexonone, has been isolated from the neutral oil of wood tar. Its constitution was determined by means of its oxidation products, potassium permanganate giving only acetic acid and α-levulinic acid.—On dibromo- and diiodobutane: a new synthesis of adipic acid, by M. l'abbé J. Hamonet.—Comparison between the nucleated and non-nucleated red blood corpuscle, by M. R. Quinton. From the point of view of osmosis the nucleated red blood corpuscle differs in its behaviour from the non-nucleated corpuscle, inasmuch as an equilibrium is attained in the former case with urea in solution, but not in the latter.—Blastoderm without an embryo, by M. Gustave Loisel.—Action of the total pressure on the chlorophyll assimilation, by M. Jean Friedel. The diminution of the total pressure tends to favour assimilation. When air containing carbonic acid is rarefied, the assimilation passes first through a minimum and then through a maximum.—On the tuberculisation of the potato, by M. Noel Bernard. It has been previously shown by the author that in certain plants the formation of tubers from the buds is a consequence and a symptom of the infection of the roots by endophytic fungi. Experiments are now given for the potato, confirming these views, and it is pointed out that if this conclusion is exact, it should be possible, by a rational culture of the potato, to increase the size and yield of the tubers.—On a new group of very basic rocks, by M. A. Lacroix.—New observations on the glacial period in the southern Carpathians, by M. E. de Martonne.—The transgressions and the regressions of the secondary seas in the basin of the Aquitaine, by M. Ph. Glangeaud.—Contribution to the study of subterranean waters. Isochronochromatic curves, by M. Félix Marboutin.

DIARY OF SOCIETIES.

THURSDAY, FEBRUARY 21.

ROYAL SOCIETY, at 4.30.—An Attempt to Estimate the Vitality of Seeds by an Electrical Method: Dr. Waller, F.R.S.—On a New Manometer, and on the Law of the Pressure of Gases between 1·5 and ·01 millimetres of Mercury: Lord Rayleigh, F.R.S.—(1) An Investigation of the Spectra of Flames resulting from Operations in the Open Hearth and "Basic" Bessemer Processes; (2) The Mineral Constituents of Dust and Soot from various Sources: Prof. Hartley, F.R.S., and Hugh Ramage.—Notes on the Spark Spectra of Silicon as rendered by Silicates: Prof. Hartley, F.R.S.

LINNEAN SOCIETY, at 8.—On the Affinities of *Æluropus melanoleucus*, Alph. Milne-Edw.: Prof. E. Ray Lankester, F.R.S., and R. Lydekker, F.R.S.—Étude d'une espèce nouvelle de Lépapèdes: M. A. Gruvel.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—If the discussion on Mr. Mordey's paper is closed, the following paper will be read:—The Electrical Power Bill of 1900: Before and After: W. L. Madgen.

CHEMICAL SOCIETY, at 8.—(1) Isomeric Hydrindamine Mandelates and Phenylchloracethydrindamides; (2) Isomeric Benzylhydrindamine bromocamphorsulphonates and some Salts of *d-l*-Hydrindamine: F. Stanley Kipping and H. Hall.—Condensation of Phenols with Esters of the Acetylene Series. IV. Benzo-γ-pyrone and its Homologues: S. Ruhemann and H. W. Bausor.—Constitution of Bromocamphoric Anhydride and Camphanic Acid: A. Lapworth and W. H. Lenton.—The Action of Acetylchlor- and Acetylbrom-aminobenzenes on Amines and Phenylhydrazine: F. D. Chattaway and K. J. P. Orton.

FRIDAY, FEBRUARY 22.

ROYAL INSTITUTION, at 9.—Metals as Fuel: Sir W. Roberts-Austen, F.R.S.

PHYSICAL SOCIETY, at 5.—How Air subjected to X-Rays loses its Discharging Property, and how it Discharges Electricity: Prof. Emilio Villari.—(1) On the Propagation of Cusped Waves and their Relation to the Primary and Secondary Focal Lines; (2) On Cyanine Prisms, and a New Method of Exhibiting Anomalous Dispersion: Prof. R. W. Wood.

THE ORIGIN OF WORLDS.

Kant's Cosmogony as in his Essay on the Retardation of the Rotation of the Earth, and his Natural History and Theory of the Heavens. With introduction, appendices, and a portrait of Thomas Wright of Durham. Edited and translated by W. Hastie, D.D., Professor of Divinity, University of Glasgow. Pp. cix + 205. (Glasgow: James Maclehose and Sons, 1900.)

IN this work Prof. Hastie has not only given us a very readable book, but has written an important chapter in the history of astronomy. His main object is to make us recognise in Kant a profound genius, and to give us reasons for this appreciation. The author was well advised, for Kant, in the domain of natural science, enjoys a somewhat nebulous reputation. Few would care to say with exactness what particular view Kant supported concerning the origin of the cosmos, to what extent he was assisted by earlier writers, or how much of his work has been approved by later physicists. It was inevitable that the work of Laplace, appearing at a later date and supported by a renown won by his successful solution of problems connected with celestial mechanics, should occupy a position of wider acknowledgment and receive the assent of those who, unable to add any support or offer effective criticism to his theory, were content to rely upon his deservedly high reputation. Thus it has come about that more than one writer has owed his knowledge of Kant to very second-hand sources, and while only very imperfectly apprehending the points of difference in the systems suggested by the two philosophers, has allowed the later to eclipse and supplant the work of the earlier writer. Perhaps it is not too much to say that until Prof. Newcomb's "Popular Astronomy" appeared, no intelligent comparison between the theories of Kant and Laplace could be found in any popular work written in English. Prof. Hastie has, however, removed any difficulty that any one might experience in endeavouring to master Kant's views at first hand, and there is no longer any excuse for incomplete knowledge. In excellent English, and we have no doubt with faithful adhesion to the original, he has given us more than all of that portion of Kant's work which the author himself considered to be supported by fair demonstrable inferences. This translation, indeed, oversteps the point at which Kant authorised the publication of his work by J. F. Gensichen in 1791. The remaining portion seems to have been too imaginative and fanciful to receive the support of Kant's maturer judgment, but Prof. Hastie has translated the whole, and the part yet unpublished may see the light if a favourable opportunity offers.

Not only has Prof. Hastie given us Kant's views in practically his own words, but by adding a sketch of the theories of other writers of the period, such as Lambert and Wright, and, later, those of Herschel and Laplace, he has reconstructed the environment in which Kant lived, and permitted us to see in some measure the extent of his acquirements and the gradual increase of later knowledge. To Wright, indeed, to whom Kant admits his obligations, the translator has rendered an act of justice by giving at very considerable length both the account of his suggestions, as they appeared in the *Hamburgische Freyen Urtheile* for 1751, and De Morgan's comments on Wright's hypothesis. Perhaps there was less reason for dealing at equal length with Lambert and the elder Herschel, but enough is given to permit the relations between these old astronomers to be readily apprehended. The result of the examination of Kant's work, and of the comparison with other writers on the same subject, has manifestly given Prof. Hastie very exalted views of Kant's power and insight; and by the use of various expressions he invites us to declare that "a greater than Newton is here."

"Newton was too resolutely opposed to hypotheses not directly founded upon empirical facts, and too anxious to keep within the limits of exact calculation, to give reins to his imagination in the physical sphere. But Kant, gifted with a rare combination of empirical observation and speculative thought, was especially equipped with a genius that could grasp and combine the 'two worlds' in one" (p. lxxxvi).

And again—

"His (Kant) evolutionary theory was thus co-extensive with the Universe, and included all its parts and all its developments. He was thus the precursor in the eighteenth century of Herbert Spencer and Darwin in the nineteenth; but he was greater than both in that he established the general principles of which they have only given particular expressions" (p. lxxxvii).

Laplace also fares badly at Prof. Hastie's discriminating hands—

"Kant, indeed, does not write with the admirable lucidity and ease of Laplace, but he has greater strength, more intensity, richer poetic vision" (p. cvii).

We doubt if this generous view of Kant's powers will meet with a ready assent from many readers. But every one will give him credit for the possession and development of one great thought. He saw and appreciated more clearly than any who had lived before him that the creation of the Universe was the result of a process, and not of an act or succession of acts, implying breaches of continuity. He unfalteringly demanded the banishment of all supernatural interferences from the ordered development of nature, and perceived the possibility of deriving the most complicated forms from the universal laws of motion regulating the simplest elements of matter. To rise above the trammels of dogmatic theology, and to give scientific expression to the evolutional processes of nature, were remarkable feats in his age and in the condition of physical science, and much may be forgiven him if in some of his details he shows a lack of accuracy, or if some of his conceptions are in formal contradiction with the principles of mechanics. And his reputation will still stand high if we freely admit that there are errors, or at least inconsistencies, in his cosmogony. There is a tendency in the very able introduction of Prof. Hastie to explain away these errors, and to contend for a closer agreement between the views of Kant and modern scientific theories than really exists. This treatment seems to us injudicious, and tends to raise a spirit of contradiction which really detracts from the very high estimate any one must form of Kant, simply considered by his work in the physical sciences.

T

Kant's announcement of the appearance of his cosmogony is found in a paper which he wrote, discussing a possible alteration in the time of the earth's axial rotation. We doubt if anything like justice has been done to Kant's memory in connection with this discussion. He there pointed out, in the clearest possible manner, two important facts which in recent times have received very considerable attention, and the early mention of which by Kant discloses a far-reaching apprehension of the operations of celestial mechanism. One is the view revived by Delaunay at the time of the controversy concerning the amount of the secular acceleration of the moon's motion, that the action of the tides must tend to diminish the time of the earth's rotation. The other is, that the explanation of the fact that the moon, in revolving round the earth, turns to it always the same hemisphere, can be traced to tidal influence. But if these two bold speculations have not met with the attention to which they are entitled, Kant himself was not a little to blame for this neglect. For he subsequently adopted the notion that the daily rotation of the earth was accelerated by the falling of heavy particles from the solid crust of the earth towards the centre, supposed to be fluid, and such particles carrying with them a greater velocity of rotation than the lighter particles which might be ascending from the centre. It is, perhaps, of no great consequence to point out here that modern analysis tends to the conclusion that our globe is solid throughout, but it is not a little curious to notice that Kant did not seem to apprehend that the introduction of a second hypothesis does not in any way affect the validity of the former argument. The possibility of the two causes operating together, and the ultimate effect depending upon the amount of their difference, does not seem to have occurred to him. But the paper as it stands in the text betrays a feverish, unphilosophical hurry. The argument is marred by misdescriptions that would have been eliminated by the exercise of more care, and one might well doubt whether Kant fully appreciated the importance of his own suggestions.

But in the presentation of his cosmogony, properly so-called, he lavished all the care and skill of which he was master. Laplace hid his suggestion of the nebular hypothesis away at the end of a volume as though he were ashamed of it, or was afraid that the introduction of more or less hypothetical matter might damage the effect of his rigorous demonstrations. Kant, on the other hand, believing that he was writing a classic for all time—perhaps he was—felt himself entitled to dedicate his work to his sovereign, and was content to base his reputation on the legitimacy of his hypotheses and the use he made of them. But mankind has, perversely enough, connected the nebular hypothesis with the name of Laplace rather than with that of Kant.

To Thomas Wright, of Durham, the author, according to Prof. G. H. Darwin, of a book of preternatural dulness, Kant is indebted for his general view of the construction and arrangement of the Milky Way. Whatever merit or originality the "grindstone theory" possesses, the credit of its discovery seems to be undoubtedly due to this author, and the additions that Kant attached to the description are not particularly happy. For he not only regarded the nebulæ as presenting distant views of remote galaxies and constellative systems in which the construction of our Milky Way was repeated, but he created a central sun about which each star had its appointed orbit, and around which it would run its course during endless ages. We cannot, therefore, follow Prof. Hastie in his assertion that Kant "improved and simplified Wright's theory, giving it a more exact scientific expression" (p. lxviii). Nor are we prepared to admit that "spectroscopic results are so far in entire harmony with Kant's view, and have only extended its range and certainty" (p. c). Spectroscopic observation has not supported the conclusion that nebulæ are due to the combined light of distant suns, so remote that the light from them, condensed into a small space, is visible to us as a tiny luminous cloud. In this place it is sufficient to refer either to the philosophic views held by Schiaparelli, or the more complete examination of these bodies of which an account has been given by Sir Norman Lockyer. Nor is it probable that the stars, collected as they are into irregular clusters or masses with comparatively vacant spaces between them, constitute a stable system. There is no evidence of the existence of a central body of vastly greater mass than the stars surrounding it, which is almost an essential feature to the maintenance of such a system.

But it may be urged that Kant's greatest success is to be found in his construction of the solar system. In the bold conception

"I assume that all the material of which the globes belonging to our solar system—all the planets and comets—consist, at the beginning of all things was decomposed into its primary elements and filled the whole space of the universe in which the bodies formed out of it now revolve" (p. 74),

he anticipated Laplace in the essential portion of the nebular hypothesis, and though his conception is marred by one great dynamical error, yet possibly his origin of the cosmos comes nearest to that at present held by the greatest authorities. If Kant's theory be maintained in detail it would seem to lead, not to a planetary system, such as at present exists, but to a central sun formed by the collection of all the matter in the "meteoritic plenum." But this may be a quite possible condition at one stage of the process, just as Laplace's hot rotating nebula, with which his hypothesis starts, may represent a later stage. For Lord Kelvin is understood to trace the solar system to an originally

"cold nebula consisting of separate atoms or of meteoric stones initially possessed of a resultant moment of momentum equal to that of the solar system. Collision at the centre will reduce them to a vapour, which then expanding far beyond Neptune's orbit will give a nebula such as Laplace postulates."[1]

But Kant's great error consists in the assumption that a motion of rotation could be produced from a state of rest by repulsive forces acting upon the rarer masses of the condensing matter, which would give rise to a whirling motion. This is to ignore the fact that the sum total of rotatory motion in a system can never be increased or diminished by the mutual action of its separate parts.

It is needless to dwell on such points as the suspected increase of eccentricity in planetary orbits with increase of distance from the sun, or the explanation offered for the varying densities of the planets with the variations of

[1] G. F. Becker, "Kant as a Natural Philosopher," *American Journal of Science*, vol. v., February 1898.

the radius vector. An effort to bring into quantitative correlation such constants as density, eccentricity, or inclinations of axis, must end in failure for Kant. He will be judged, not by details, but on the general principle by which he claimed to have arrived at a just comprehension of a complete cosmogony. Similarly, one may pass over his genesis of satellites and the formation of Saturn's ring. Of the former it is sufficient to say that both Kant and Laplace saw in the existence of satellites the repetition on a small scale of the formation of the solar system. We know now the extreme probability that the moon owes its existence to a quite unique arrangement, and it would be hazardous to affirm that any one process has been operative in more than one planet. With regard to the latter, if the existence of a ring about Saturn is suggestive of the manner in which planets came into existence, neither Kant nor Laplace could give sufficient reasons to account for the stable condition of the ring in that system and the instability in others.

The problem of the ordered solar system is one around which much future controversy will arise, and possibly the ambition of neither the astronomer nor the physicist will go further than to suggest how it might have been effected on a plan that does not contradict any known physical laws or inferences. This is very different from saying how it actually "rose out of chaos." Prof. Hastie quotes with approval a remark of Kant, "that it is more difficult to explain the genesis of a caterpillar than the origin of a world." If this be true, it may be due to the fact that we know less about the fabric of the Universe than of the caterpillar, and it is consequently easier to be convicted of error in the smaller than in the greater matter. Kant, together with all makers of cosmogonies, enjoys the advantage that the accuracy of the theories cannot be submitted to any adequate test. W. E. P.

THE HERPETOLOGY OF NORTH AMERICA.

The Crocodilians, Lizards, and Snakes of North America. By E. D. Cope. Reprinted from the Report of the U.S. National Museum for 1898, pp. 153–1270. With woodcuts and 36 plates. (Washington, 1900.)

THE eminent position held by the late Prof. Cope among workers on the taxonomy of vertebrates in the latter half of the past century is chiefly due to the fact that, as has been the case with Prof. Gegenbaur in the field of comparative anatomy, he applied the teachings of the evolutionary theory from the very outset, at a time when other zoologists, imbued with the Cuvierian and Müllerian principles, were still striving at natural arrangements on physiological bases. The ideas set forth in the revolutionary essays on the classification of Batrachians and Lizards, by which he first made his name known, though at first received with little favour by his fellow-workers in Europe, have gradually made their way, and may be said to have well stood the test of time. Although considerably modified in many points both by himself and by others in the intervening thirty-five years, Cope's views hold the field to a greater extent than those of any other taxonomist of the same period. Later in his career, similar attempts at the general classification of Reptiles and Fishes have, in the opinion of the reviewer, been equally successful.

The quick perception of the importance of apparently trivial anatomical details, the veritable instinct with which he realised their phylogenetic bearing and selected them for the purpose of connecting forms widely remote in the systems of his predecessors, and led to conclusions which have, in many instances, ultimately been confirmed by palæontological discoveries, have rendered his name famous in Europe as well as in America. During the later years of his life, however, hasty and careless work, a constant striving at originality, to a certain extent marred the productions of his never-ceasing activity. This may be said of his latest attempts at improving the classification of the Lizards and Snakes, the results of which are incorporated in the thick volume of over 1100 pages now issued by the Smithsonian Institution. It is not stated by whom the work has been seen through the press, nor whether and to what extent the original MS. has been touched up, an omission through which it appears uncertain whether the late author or the editor is responsible for various startling errors which one feels disinclined to ascribe to the former.

The present volume forms part of a series of monographs intended to illustrate the cold-blooded lung-breathers of North America, a work which was devised many years ago by the late Prof. Baird, whose MS. and a number of carefully-drawn figures were placed in the hands of Prof. Cope in 1864. The Batrachians appeared in 1889, the Chelonians were to have been described by Prof. Baur, whose death so nearly followed that of the author of the present treatise, dealing with the remaining orders, viz., *Loricata* (Crocodiles) and *Squamata* (Lizards and Snakes).

As regards the first of these two orders, which includes only two North American living types, *Alligator mississippiensis* and *Crocodilus americanus*, it seems surprising that so advanced a reformer of classification should still have adhered to the inclusion of the *Parasuchia* among the Crocodilians. These Triassic types differ in so many respects from the later *Eusuchia*, and have so much in common with the Rhynchocephalians and the Sauropodous Dinosaurs, that their separation as a distinct order (*Thecodontia*) appears imperative if exact definitions of the allied groups are to be attempted.

Prof. Cope's arrangement by which the *Lacertilia*, or *Sauria* as he prefers to call them, and *Ophidia*, forming the bulk of the fauna, are brigaded under *Squamata* is well in accordance with the present state of knowledge, the supposed characters on which the two groups were formerly allowed ordinal rank being quite insufficient for that purpose. But, in the opinion of the reviewer, a classification in which the *Rhiptoglossa* (Chameleons) are regarded as a mere super-family of Lizards, equivalent with the *Pachyglossa* (*Agamidae*, *Iguanidae*), *Nyctisaura* (*Geckonidae*, *Eublepharidae*), *Uroplatoidea*, *Thecaglossa* (*Varanidae*), *Helodermatoidea*, *Diploglossa* (*Zonuridae*, *Pygopodidae*, *Anguidae*, *Xenosauridae*), *Leptoglossa* (*Teïidae*, *Xantusiidae*, *Lacertidae*, *Gerrhosauridae*, *Scincidae*, *Acontiidae*, *Dibamidae*, *Anelytropidae*), *Annielloidea* and *Annulati* (*Amphisbaenidae*), absolutely fails to express the degree of relationship between them and the members of other families; and if one turns to the synopsis on pp. 200 and 201, in which the distinctive features of the

primary groups, here inadvertently termed "orders" and "suborders" (*cf.* p. 178, where the *Sauria* are described as a suborder), are set forth, one cannot fail to be struck by the want of logic and of perception of proportions which characterises the new arrangement. It may also be pointed out that the group *Annielloidea* has been omitted from the synopsis; this is but one out of many clerical oversights of a similar kind which a rapid inspection of the volume reveals.

A glance at the definitions of the species in the difficult genera, such as *Sceloporus* and *Cnemidophorus*, shows that the subject has not been mastered. An attempt to name an extensive series of *Scelopori* with the aid of the key given would, it can be predicted, result in failure.

In the classification of the snakes, the author agrees with the reviewer in the main divisions. The innovations are mainly due to the consideration of the structure of the intermittent organ or "hemipenes" of the male, by the use of which character many changes have been introduced in the limits of the genera and in their groupings, changes which are not likely to meet with general acceptance. Far too few species have as yet been tested with regard to this character, and Cope himself admits of occasional exceptions, which have turned up in the course of his investigations, such as when one of the paired organs has proved to belong to a division of his system different from that of its fellow on the same specimen. *A priori*, it does not seem that the development of folds and spines on such an organ is at all likely to have so deep a signification as to assist in establishing subfamilies and genera; to adduce a somewhat parallel example, we might as well attempt to employ the differences in the nuptial excrescences of male Batrachians for the definition of genera and even higher groups. And if we are to judge of the value of the character by the changes which its consideration warrants in the groupings of the genera, its introduction in the system does not appear as anything in the way of an improvement.

The investigation of the lung characters, to which the author has devoted so much attention, is a more useful piece of work, so far as taxonomy is concerned, and it may be mentioned that through it the view once propounded by the writer of this notice that the Amphisbænids may be directly derived from degraded types of Teiids, has proved to be untenable.

Allusion has been made above to some extraordinary errors which have crept into this work. Two may be mentioned, *à propos* of snakes, as illustrations:—P. 1127, the *Hydrophiinae* are stated to "leave the water to deposit their eggs"; p. 1129, *Echis carinatus* is described as the "Krait" of India.

The illustrations are numerous and for the most part excellent, and an interesting essay on the geographical distribution of Batrachians and Reptiles concludes this monograph, which, in spite of its imperfections, such as it is a reviewer's duty to point out, will prove of great service to the student of a highly interesting but most difficult group of animals, our knowledge of which has been so greatly advanced by the genius and industry of Prof. Cope. The work is also useful as a catalogue of the specimens preserved in the United States National Museum in Washington. G. A. B.

PRACTICAL PHOTOMETRY.

Photometrical Measurements. By W. M. Stine, Ph.D., Williamson Professor of Engineering, Swarthmore College. Pp. xi+270. Illustrated. (New York: The Macmillan Company. London: Macmillan and Co., Ltd., 1900.) Price 6*s*. 6*d*. net.

AS a "manual for the general practice of photometry, with especial reference to the photometry of arc and incandescent lamps," this work will be found useful. Most of the descriptions of photometers are clear and well illustrated, and much practical information about standards of light is collected together. That strange medley of apparatus enshrined in an expensive tabernacle of mahogany and velvet called by gas engineers a "photometer" is not even mentioned, possibly because the book is of American origin. Photometers, and those parts of the art of photometry which are of use to engineers, may be defined without much difficulty, and the apparatus and methods suitable for the research laboratory may be grouped together; when to these is added the theory of the subject, the whole ground of photometry is covered. But the author makes no such distinctions, and the value of his work suffers. While his reference to spectro-photometry is meagre, and the bolometer is dismissed in less than six lines, he drags in double integration to determine the mean spherical intensity of a purely academical case of distribution. On the other hand, he treats possible cases of distribution in a clear and practical way. The description of a Bunsen photometer in the crude form of a screen without mirrors or prisms, and an ancient algebraical theory of the Bunsen screen, containing no reference to the angle of emission or direction of view, marks the author, as do many other passages, as a science teacher. He is in good company; there is hardly a text-book of physics in English in which that useless affair is not represented as a Bunsen photometer. In common with most science teachers, he assumes that the shadows of a Rumford photometer must be widely separated, and he very properly alludes to the lack of sensitiveness which results. When Lord Kelvin said that no one could need a better photometer than a pencil and a white card he knew that the edges of the shadows should meet, and, it may be added, that the shadows should completely cover the card. The little-known, but valuable, Conroy, Ritchie and Thompson photometers, varieties of the Rumford, are described, and the somewhat over-rated Lummer-Brodhun apparatus is criticised. To describe the use of the rotating sector without allusion to Abney, the light of the arc without reference to Fleming, S. P. Thompson or Mrs. Ayrton, and measurement of the mean spherical candle power of arcs without reference to Blondel, can hardly be excused by the attempt to compress the whole book into 261 pages. That the author is a professor of engineering may account for the excellence of the practical parts of the manual; but that, being a professor, some of the theoretical parts are so obscure is strange.

He must needs allude to "the logarithm of the ratio" in defining Fechner's law, because he is a professor; he goes on to give a lucid arithmetical example, because he is an engineering professor, but after a page relapses

hopelessly into totally unnecessary integration in order to get back to the professorial logarithm.

The nomenclature of photometrical quantities is dismissed in a few lines with the very true remark that "the tendency toward particular nomenclature of physical quantities has been carried to a burdensome excess in many cases, until it has assumed the nature of scientific fetichism." "The attempts" of Hospitalier are alluded to, but the author has paid so little attention to the matter that he falls into sad confusion in the use of the expression "illumination." The word is used in half a dozen senses—as a sensation, as a flux, as a quantity of light, and so on. It is true that the "lux" of Preece or Hospitalier are no guide, but the "carcel-metre" or the unscientific "candle-foot," when once understood, leave not the slightest ambiguity about the meaning of "illumination."

The chapter on standards of light is excellent, but the table of comparisons of standards, taken from Laporte, does not include the British candle. Only two items out of a dozen appear to agree with the more complete table of Palaz. The British candle, with all the refinements of the gas referees, is not a unit which does credit to physical science, but it is at least as definitely known, reproducible and measurable as any other standard of light.

The arrangement, illustrations and index are good; the spelling is English. A. P. T.

OUR BOOK SHELF.

The Nature and Work of Plants: an Introduction to the Study of Botany. By D. T. MacDougal, Ph.D., Director of the Laboratories, New York Botanic Garden. Pp. xvii + 218. (New York: The Macmillan Co. London: Macmillan and Co., Ltd., 1900.)

THIS is a bright and readable little volume, in which plants are treated of mainly from a natural history and physiological point of view. It deserves to be successful, if only as showing that it is possible to gain a fairly considerable, and certainly intelligent, insight into the ways of plants, and that without first mastering the mass of technical detail which too often renders elementary books on botany so repulsive to beginners.

The author commences with a general account of the materials of which plants are composed, and of the structures of which they are built up, the student being led to investigate for himself the different facts and principles enunciated. The phenomena of reproduction, irritability and the like are introduced as objects of observation, and in such a way as to arouse, rather than by satiating to quench, curiosity. The seed and fruit are more fully dealt with, as they afford examples in which adaptations to special purposes can be made out with some degree of clearness, and their individual peculiarities are well explained. If one feels some doubt as to the wisdom of selecting the coconut as an introductory example of a fruit, one cannot complain of the mode in which its structure is treated. The very interesting case of *Xanthium*, in which two fruits are contained in a common sheath, one seed of which germinates in one year whilst its fellow remains dormant till the following season, will probably be new to some readers on this side the Atlantic.

A short chapter on plant societies closes the volume, which may be warmly commended as one likely to excite an interest in many people who fancy that the acquirement of a more or less complicated vocabulary is an essential preliminary to a scientific study of plants. Naturally, the book is not without its faults. Some of these seem to be those of carelessness, of which there is an example on p. 11 in the implication that a dried plant consists of charcoal (!) and ash. But these defects are not numerous, and do not seriously affect the general excellence of the book

Practical Coal Mining. By George L. Kerr. Pp. x + 462. (London: Charles Griffin and Company, Ltd., 1900.)

IN the vigorous outburst of technical literature that the last few years have witnessed, the subject of mining has not been forgotten, and the student of this subject has his choice of a fair number of works of a high degree of merit, amongst which those published by Messrs. Griffin and Co. take foremost rank. It was therefore to be expected that a new book on coal mining, issued by these same publishers, ought to surpass anything previously written on this subject, or at any rate to present features of especial importance. It is to be regretted that these anticipations have been very far from being realised, and, indeed, that it is difficult to discover anything in the work now under review that justifies its publication. It is very largely made up of extracts from the works already referred to, as well as from others, nor are these extracts by any means the worst part of the book. The author's style is far from clear, and many passages might be quoted that would be quite unintelligible to any one who was not acquainted beforehand with the subject-matter; this obscurity of languages often merges into inaccuracy and want of precision—the latter fault being one of the most dangerous that could well be found in a book intended to be placed in the hands of a student. A couple of examples of this fault may be cited: on p. 3 the author writes that "the line at right angles to the direction of 'dip' is called the 'strike,'" a definition that is not true unless qualified by the statement that the line referred to is a line within the bed; it is obvious that there may be an infinite number of lines at right angles to the direction of dip, but only one of these is the strike. Again, on p. 326, we find the following: "When two shafts are sunk and connected by a passage, and the density (weight) of air in the two shafts is equal, no current of air will circulate, no matter what their respective sizes may be." This, again, is only true if it be postulated that both shafts are of precisely the same depth, otherwise an air current may circulate.

The author is weak whenever he touches upon scientific ground; he uses mechanical formulas without apparently appreciating their limitations, as, for instance, when he applies formulas for the bending of columns, ignoring the fact that these are only applicable within the elastic limit. Similarly, his mechanical conceptions of the work done by the winding engine (p. 221) are incorrect. That his chemistry is not much more satisfactory may be judged from the occurrence of such phrases as "glycerine nitrate" for nitro-glycerine, &c.

The best chapter in the book is that on "Modes of Working," the methods of coal-getting in use in Scotland being well described. Indeed, had Mr. Kerr confined himself to a small book describing merely those points in which Scotch practice differs from the English, notably in shaft-sinking, coal-getting and haulage, he would have produced a contribution of distinct value to the literature of coal mining, a phrase that can, unfortunately, not be applied to his present more ambitious attempt. H. LOUIS.

Bookkeeping for Business Men. By J. Thornton and S. W. Thornton. Pp. vi + 185. (London: Macmillan and Co., Ltd., 1900.) Price 3*s.* 6*d.*

BOOKKEEPING is only the application of common-sense principles to the classification and systemisation of accounts. Its purpose is to show how the financial facts of a business may be expressed in the clearest and shortest

way, so that the financial position can be readily understood. A pupil who has been taught arithmetic in a reasonable way can adapt his knowledge to the forms of bookkeeping in a few weeks when placed in an office. For people who have not had the advantage of a rational education, it is necessary to draw up hard and fast rules, which must be obeyed in order to keep accounts intelligibly. The volume under notice does this, by showing as simply as possible how a trader unfamiliar with bookkeeping may construct, keep and balance a set of account books suited to his own business. A set of "Automatic Balancing Charts" is published separately as a supplement to the book, and they are drawn up in such a way that it is almost impossible for a person of average intelligence to make an incorrect entry upon them. Both the book and the charts should prove of service to business men unfamiliar with the intricacies of bookkeeping.

Reports from the Laboratory of the Royal College of Physicians, Edinburgh. Edited by Sir Batty Tuke, M.D., and D. Noel Paton, M.D. Vol. vii. (Edinburgh: Oliver and Boyd, 1900.)

THIS volume consists of a series of original papers which, since the end of 1897, have emanated from the laboratory of the Royal College of Physicians of Edinburgh. Practically all these papers have been published previously in the medical or scientific journals, and in this form have no doubt been read by those interested in their subject-matter. This is, however, perhaps only partially true of two reports which were presented respectively to the Fishery Board for Scotland and to the Prison Commission for Scotland. The first report consists of sixteen monographs on the life-history and the physiology, under varying conditions, of the salmon; and concludes with a monograph, by Dr. Dunlop, upon the food value of the salmon at different seasons, and obtained from different sources.

Dr. Dunlop is also the author of a report to the Prison Commission for Scotland upon prision dietaries. The report seems to be an exhaustive one, and contains many suggestions with regard to the adaptation of the diets in prisons to the varying conditions and labour employments of the prisoners.

Mother, Baby and Nursery. By Gènevieve Tucker, M.D. Pp. xvi + 193. (London: T. Fisher Unwin, 1900.) Price 1*s.*

THIS is one of the many manuals written for the guidance of young mothers. The writer is an American doctor, but suitable to every mother are the clear and practical directions on the management of herself and her infant. The earlier chapters are concerned with heredity and the conditions favourable for the unborn child. The practical advice is valuable, but it is misleading that the author's opinions on questions of heredity are stated as generally acknowledged facts. The chapters on the care of the infant are suggestive and helpful, and the importance of early training in good habits beginning during the first month of life is insisted upon duly and wisely; but the following advice is extraordinary and *not* to be recommended: "Take a good-sized raisin, cut open, taking out the seeds, put it on the umbilicus." A chapter containing a classification of the diatheses of infants (scrofulous, tuberculous types, &c.) seems out of place in a manual of this description. At the end of the book there is a short and emphatic summary of what is and what is not to be done in the nursery; but among the "nursery don'ts" we notice the omission of a warning against a practice too common, at any rate, in this country, namely, the use of so-called baby-soothers.

Interest is added to the book by the introduction of photographs of young children, but we dislike to see advertisements embodied in the text.

LETTERS TO THE EDITOR.

Vortex Rings.

IN the course of some experiments preparatory to a lecture on vortex rings, I have introduced certain modifications which may be of interest to teachers and students of science.

The classic vortex-box is too well known to require much description. Our apparatus, which is rather larger than those in common use, is a pine box measuring about a metre each way, with a circular hole 25 cms. in diameter in one end. Two pieces of heavy rubber tubing are stretched diagonally across the opposite or open end, which is then covered with black enamel cloth tacked on rather loosely. The object of the rubber chords is to give the recoil necessary after the expulsion of a ring to prepare the box for a second discharge. Such a box will project air vortices of great power, the slap of the ring against the brick wall of the lecture hall being distinctly audible, resembling the sound of a flip with a towel. An audience can be given a vivid idea of the quasi-rigidity of a fluid in rotation by projecting these invisible rings in rapid succession into the auditorium, the impact of the ring on the face reminding one of a blow with a compact tuft of cotton.

For rendering the rings visible I have found that by far the best results can be obtained by conducting ammonia and hydrochloric acid gases into the box through rubber tubes leading to two flasks in which NH_4OH and HCl are boiling. Photographs of large rings made in this way are reproduced in Fig. 1, the side view being particularly interesting, showing the comet-like tail formed by the stripping off of the outer portions of the

FIG. 1.

ring by atmospheric friction as it moves forward. It is needless to say that the experiment with the visible rings should be left until the end of the lecture. The power of the air-rings can be shown by directing them against a flat pasteboard box, stood on end at some distance from the vortex apparatus, the box being at once overturned or even driven off on to the floor. A large cluster of burning gas jets can be extinguished by the impact of a ring, a modification of which experiment can be shown on a small scale by shooting a capped shell in a shot-gun at a candle several paces off. If one's aim is good the candle will be extinguished by the invisible vortex.

For showing the elasticity of the rings by bouncing one off the other, I find that the best plan is to drive two in rapid succession from the box, the second being projected with a slightly greater velocity than the first, all experiments that I have made with twin boxes having yielded unsatisfactory results.

Though the large vortices obtained with an apparatus of this description are most suitable for lecture purposes, I find that much more beautiful and symmetrical rings can be made with tobacco smoke blown from a paper or glass tube about 2·5 cms. in diameter. It is necessary to practice a little to learn just the nature and strength of the most suitable puff. Rings blown in this way in still air near a lamp or in full sunlight, when viewed laterally, show the spiral stream lines in a most beautiful manner. I have succeeded in photographing one of these rings in the following way. An instantaneous drop shutter was fitted to the door of a dark room, and an arc-lamp focussed on its aperture by means of a large concave mirror. The shutter was a simple affair, merely an aluminium slide operated with an elastic band, giving an exposure of 1/300 of a second. A photo-

graphic plate was set on edge in the dark room in such a position that it would be illuminated by the divergent beam coming from the image of the arc when the shutter was opened. A ruby lamp was placed in front of the plate, and rings were then blown from a tube in front of the sensitive film. As soon as a good ring, symmetrical in form and not moving too fast, was seen to be in front of the plate, a string leading to the shutter was pulled and the plate illuminated with a dazzling flash. The ring casts a perfectly sharp shadow owing to the small size and distance of the source of light; the resulting picture is reproduced in Fig. 2. The ring is seen to consist of a layer of smoke and a layer of transparent air, wound up in a spiral of a dozen or more complete turns.

The angular velocity of rotation appears to increase as the core of the ring is approached, the inner portions being screened from friction, if we may use the term, by the rotating layers surrounding them. This can be very nicely shown by differenti-

FIG. 2.

ating the core, forming an air ring with a smoke core. If we make a small vortex box with a hole, say 2 cms. in diameter, fill it with smoke and push very gently against the diaphragm, a fat ring emerges which rotates in a very lazy fashion, to all appearances. If, however, we clear the air of smoke, pour in a few drops of ammonia and brush a little strong HCl around the lower part of the aperture, the smoke forms in a thin layer around the under side of the hole. Giving the same gentle push on the diaphragm, we find that the smoke goes to the core, the rest of the ring being invisible, the visible part of the vortex

FIG. 3.

spinning with a surprisingly high velocity. Considerable knack is required to form these thin crescent-like vortices, the best results being usually attained after quite a number of attempts have been made. A drawing of one of these smoke-cores is shown in Fig. 3. The actual size of the vortex being indicated by dotted lines, it is instructive as showing that the air which grazes the edge of the aperture goes to the core of the ring. The experiment does not work very well on a large scale, though I have had some success by volatilising sal ammoniac around the upper edge of the aperture by means of a zig-zag iron wire heated by a current.

By taking proper precautions we can locate the smoke elsewhere, forming a perfect half-ring, as is shown in Fig. 4, illustrating in a striking manner that the existence of the ring depends in no way on the presence of the smoke. The best way to form these half-rings is to breathe smoke very gently into a paper tube, allowing it to flow along the bottom, until the end is reached, when a ring is expelled by a gentle puff. A large test tube with a hole blown in the bottom is perhaps preferable, since the condition of things inside can be watched. It is easy enough to get a ring with most of the smoke in the lower half, but to get a ring, one half of which is wholly invisible, the

FIG. 4.

smoke ending abruptly at a sharply defined edge, as shown in the illustration, requires a good deal of practice. I have tried fully half-a-dozen different schemes for getting these half-rings on a large scale, but no one of them gave results worth mentioning. The hot wire with the sal ammoniac seemed to be the most promising method, but I was unable to get the sharp cut edge which is the most striking feature of the small rings blown from a tube.

In accounting for the formation of vortex rings, the rotary motion is often ascribed to friction between the issuing air-jet and the edge of the aperture. It is, however, friction with the

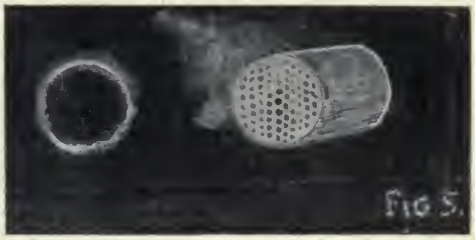

FIG. 5.

exterior air that is for the most part responsible for the vortices. To illustrate this point I have devised a vortex box in which friction with the edge of the aperture is eliminated, or rather compensated, by making it equal over the entire cross-section of the issuing jet.

The bottom of a cylindrical tin box is drilled with some 200 small holes, each about 1·7 mm. in diameter. If the box be filled with smoke and a sharp puff of air delivered at the open end, a beautiful vortex ring will be thrown off from the cullender surface (Fig. 5). We may even cover the end of a paper tub

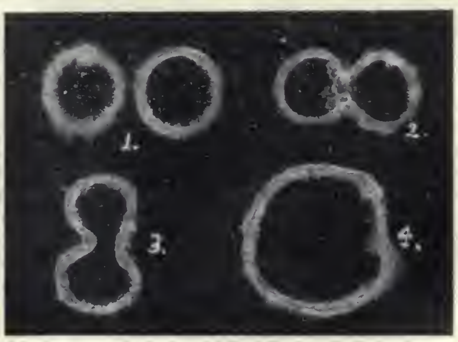

FIG. 6.

with a piece of linen cloth, tightly stretched, and blow smoke rings with it.

In experimenting with a box provided with two circular apertures I have observed the fusion of two rings moving side by side into a single large ring. If the rings have a high velocity of rotation they will bounce apart, but if they are sluggish they

will unite. At the moment of union the form of the vortex is very unstable, being an extreme case of the vibrating elliptical ring. It at once springs from a horizontal dumb-bell into a vertical dumb-bell, so rapidly that the eye can scarcely follow the change, and then slowly oscillates into the circular form as shown in Fig. 6. This same phenomenon can be shown with two paper tubes held in opposite corners of the mouth and nearly parallel to each other. The air in the room must be as still as possible in either case. R. W. WOOD.

University of Wisconsin, Madison.

Dust-tight Cases for Museums.

THE new geological museum now being erected here will have high windows and a long south aspect. The effect of this will be that the sun will fall suddenly on glazed cases and as suddenly pass off them, thus by the expansion and contraction of the air causing dust-carrying currents to force themselves through every chink. From this cause it costs about three times as much to keep cases and specimens clean on the side exposed to the sun as it does in the shaded part of a museum. This may be obviated by elastic diaphragms (which would hardly allow sufficient movement for such large cases as ours) or by small sliding shutters packed with cotton-wool something like Tyndall's respirators.

Can any of your readers refer us to museums in which such a system has been tried, or give us any advice on the subject before our cases have been built? T. MCKENNY HUGHES.

Woodwardian Museum, Cambridge, February 19.

Audibility of the Sound of Firing on February 1.

SIR W. J. HERSCHEL'S letter is very interesting, and I should like to make a few remarks upon it. To begin with, it must, I think, be granted that the discharge of the guns was almost simultaneous. The special correspondent of the *Times* on board the *Majestic* says, "and then simultaneously all the vessels in the long lines joined in, like the tolling of the passing bell." And the special correspondent of the *Times* at Osborne says: "A minute's interval . . . again the quick red flashes down the line, and again the dilatory roar." But why do we find the full minute's interval at Eastbourne, and three reverberations a minute at Oxford? Assuming that there was no firing at Windsor, the reason, I think, must be sought for in the very different character of the roads the sound had to travel over to reach these respective places. In our case the road was all over the sea with the exception of a few miles of low-lying land at Selsey Bill. On the other hand, to reach Oxford the sound would be greatly impeded by the contour of the land, to say nothing of some possible echo from the high ground of the Isle of Wight. Independently of Sir W. J. Herschel's letter, I have grounds for thinking that the sound followed the course of the valleys, and it is possible that the separate reports per minute emerged by as many different channels of passage and of echo. To have received the sound in a straight line, that is to say, to have been high enough to have seen the ships at Spithead, one would have had to have been at an elevation of somewhere about 2800 feet at Eastbourne and 3200 feet at Oxford.

Eastbourne. H. D. G.

Influence of Physical Agents on Bacteria.

IN your report of Dr. Allan Macfadyen's lecture on the influence of physical agents on bacteria (p. 359), I should like to call attention to one point. Dr. Macfadyen suggests that since phosphorescent bacteria regain their power of emitting light after being cooled to the temperature of liquid hydrogen, it may be the case that life is not dependent for its existence on chemical reactions. Because, says he, at the temperature of liquid hydrogen, *e.g.* $-250°$ C., all chemical reactions are well-nigh, if not absolutely, at a standstill, if life were dependent on chemical reactions for its continuance, at that low temperature life would be destroyed. I would submit that this is a case of *non sequitur*. It appears exceedingly probable that the action of excessive cold in *suspending* and stopping vital phenomena, while not *destroying* the capacity of organisms to resume their vital activities, supports the prevalent view that life is dependent on chemical processes. For may it not be that excessive cold, while preventing the vital processes from taking place, by no means alters the chemical constitution of the complicated molecules, the interactions of which normally produce vital phenomena, and leave these molecules, which one may call biogens or anything else, in exactly the same state as they were immediately before the onset of excessive cold, ready as soon as the conditions become suitable once more to resume those vital processes which are known as metabolism.

As an illustration of what I mean I will quote a case of inorganic phosphorescence. It is well known that phosphorus is slowly oxidised in air and emits light at the same time. This reaction takes place when the air is at the pressure of the atmosphere, and the partial pressure of the oxygen is one-fifth of an atmosphere. If, now, the pressure of the air be made equal to five atmospheres, or if the air be replaced by pure oxygen at a pressure of one atmosphere, in both of which cases the pressure of oxygen is five times as great as before, the oxidation ceases and the phosphorescence vanishes. But this is only because the conditions are unsuitable, the constitution of the phosphorus and the oxygen is unaltered, and as soon as the pressure of the oxygen is lowered the phosphorescence begins once more. In both cases, the bacteria and the phosphorus, the action of the physical agent—in the one case cold, in the other pressure—is merely to render the conditions unsuitable for the appearance of the phenomenon, and not to destroy the possibility of its subsequent revival. H. D. D.

Balliol College, Oxford, February 10.

Malaria and Mosquitoes.

I WAS stationed in Karachi, Sind, for more than twenty years. There was undoubtedly a strong belief with the Indians that the disturbance of ground for building led to fever; building operations may be estimated by the fact that I went to a city of 45,000 inhabitants and left 130,000. Not long before I left, the ground of the native town was disturbed by the installation for the first time of a system of underground drainage. I think, but am not sure, this was followed by an outbreak of fever.

Qua mosquitoes, may there not be a distinction between malarious and ordinary fever. F. C. CONSTABLE.

Wick Court, near Bristol, February 24.

Snow Crystals.

AFTER the recent heavy snow in this district, the slight fall yesterday afternoon did not, at first, attract much attention, appearing like sleet to the casual observer. It proved, however, to be of an unusual character, consisting chiefly of beautifully-formed single crystals. It was remarked that "it was snowing stars;" and the ground became covered with myriads of them, varying in size, some being a quarter of an inch in diameter. These "frost flowers" appear to have been common enough in Tyndall's Alpine experiences, but are, I imagine, rarely seen in England upon this scale. The thermometer registered 30° Fahr., and it would be interesting to know if this phenomenon was peculiar to the High Peak district, and what are the conditions conducing to such a display. WM. GEE.

Buxton, February 19.

A "NEW STAR" IN PERSEUS.

WE have received the following:—*Edinburgh Circular*, No. 54. A new star was discovered in Perseus, by Dr. T. D. Anderson of this city, on February 21, 14h. 40m. G.M.T. The star was then of the 2·7 magnitude, and shone with a bluish-white light. Dr. Anderson gave as its approximate place for 1901·0:—

R.A. 3h. 24m. 25s. Decl. + 43° 34'.

At 6h. 58m. G.M.T., on the 22nd, the undersigned estimated the Nova as 0·3 magnitude brighter than α Tauri, and at 8h. 10m. considered it equal to Procyon, which it closely resembled in colour.

On the 23rd, at 8h. 10m. G.M.T., Dr. Halm and Mr. Clark found the new star 0·2 magnitude brighter than Capella.

A direct-vision prism on the 6-inch refractor showed nothing beyond a perfectly continuous spectrum. With the large Cooke spectroscope on the 15-inch equatorial the first impression was the same as with the smaller

apparatus; but on closer examination about half a dozen delicate dark (Fraunhofer) lines were made out by Dr. Halm, extending from a little below D to about F. The spectrum of the Nova, at its present stage, is therefore of a distinct but feebly developed solar type. The existence of these lines I was able to confirm, but the sky became gradually obscured before their positions could be satisfactorily determined.

At about the same hour a photograph of the Nova was secured by Mr. Heath at a time when all the neighbouring stars were obscured by haze. Except a very short interval on the 23rd, the sky here has been completely overcast since the 22nd.

The Nova was independently discovered by Mr. J. E. Gore at Dublin at 11h. 15m. Dublin time on the 22nd, and by Mr. W. B. Dodd and Mr. H. Wake, of Whitehaven, on the 23rd inst. RALPH COPELAND.

Royal Observatory, Edinburgh, February 25.

On the night of the 25th observations were made at the Solar Physics Observatory, South Kensington, the general results of which have been stated by Sir N. Lockyer as follows in a letter to the *Times*:—

(1) The spectrum strongly recalls that of Nova Aurigæ.

(2) There are at least two light sources involved; one with a dark-line spectrum, the other giving chiefly the bright lines of hydrogen, helium, asterium and calcium.

(3) Some of the bright lines are probably reversed.

(4) The broadening of the bright lines is considerably greater than that observed in Nova Aurigæ.

(5) It has been determined by a comparison spectrum of Bellatrix, on the same plate, that the middle of the bright lines occupies nearly the normal position in the spectrum; the greatest breadth of lines observed extends over some 30 tenth-mètres.

(6) The centres of the bright and dark lines are separated by about 15 tenth-mètres, showing a differential velocity of somewhere about 700 miles per second between the colliding light sources.

(7) The star is keeping up its magnitude so far as may be gathered from a very brief observation made between clouds on Friday. To-night (February 25) it has been brighter than Aldebaran, slightly less bright than Capella.

PHOSPHORESCENCE AS A SOURCE OF ILLUMINATION IN PHOTOGRAPHY.

IN certain libraries there exists a fixed rule that no books may be removed. This being so, all extracts and copies of plates and engravings have to be made in the libraries. Reproduction by the methods of ordinary photography is most inconvenient, since the employment of artificial light is strictly prohibited; also the introduction of a camera, and its manipulation in a library, are surrounded by many difficulties. These circumstances led me to devise the following method for obtaining copies of plates, engravings, printing and writing. A piece of cardboard is coated with a phosphorescent substance, and, after sufficient exposure to the light of the sun or of an arc lamp, it is placed at the back of the engraving or writing to be copied; on the face of the engraving or writing a dry photographic plate is placed, and then the book is closed for a certain time, depending on the nature and thickness of the paper used in the book. I find that the period of time lies between eighteen and sixty minutes. The plate is then withdrawn and stored in a dark box for development. The dry plate is easily manipulated under a cloth, which shuts off all light and covers the book during the operation. The results are sufficiently good for most purposes—in the case of some papers the fibrous structure is shown; this very slightly detracts from the clearness of the copies made by this process. Neither the luminous substance nor the dry plate injure the book in any way, so that the method may be employed in the case of valuable prints and engravings (Fig. 1). If films be used instead of plates, a large number of copies of different engravings in the same book may be made at the same time. The time of exposure to the phosphorescent backing is shortened considerably by placing the phosphorescent card on a warm surface, such as that of a metal vessel heated to about 20° C. with hot water;

FIG. 1.

when films are employed, this temperature should not be exceeded. In an experiment made in the laboratory I found that the phosphorescent substance under normal barometric pressure became brightly luminous when subjected to the brush discharge of a Tesla inductor; the discharge from an ordinary induction coil fails to produce the same effects. F. JERVIS-SMITH.

THE ROYAL SOCIETY'S ADDRESS TO THE KING.

ON Saturday last His Majesty the King received deputations with addresses from the Universities of Oxford and Cambridge, General Assembly of the Church of Scotland, the Corporation of the City of Liverpool, and the Royal Society.

The Royal Society was represented by Sir William Huggins, K.C.B. (president), Mr. A. B. Kempe, treasurer (mover), Sir Michael Foster, M.P., secretary (seconder), Dr. T. E. Thorpe, C.B. (foreign secretary), Lord Lister, Lord Kelvin and Sir J. D. Hooker (past presidents), and Mr. W. H. M. Christie, C.B., Astronomer Royal (vice-president). The following was their address:—

TO THE KING'S MOST EXCELLENT MAJESTY.

The Humble Address of the President, Council, and Fellows of the Royal Society for Promoting Natural Knowledge.

Most Gracious Sovereign,—We, your Majesty's most dutiful and loyal subjects the President, Council, and Fellows of the Royal Society of London for Promoting Natural Knowledge, humbly beg leave to offer our deepest and most heartfelt sympathy with your Majesty in the great sorrow which has befallen you in the death of your beloved mother, our late Sovereign Lady the Queen. Your Majesty's loss is our loss, a loss not only to ourselves, not only to all your Majesty's subjects throughout the Empire, but to the whole world. During your beloved mother's wise and beneficent reign under her thoughtful fostering care that natural knowledge which the society was founded to promote has been promoted to an extent and in ways never known before, and we feel sure that not in our time only, but in the years to come, to the story of the advance of science in the past century will be most closely linked the memory of the goodness, the wisdom, the peerless worth of the august and

beloved lady whose death has now plunged us into the deepest grief.

While thus uttering words of sorrow we ask leave, sire, at the same time, to lay at your Majesty's feet our unfeigned and heartfelt congratulation upon your Majesty's accession to the Throne of your ancestors to reign over a people to whom happily your Majesty is no stranger, but who have by many experiences learned to recognise your great worth, and have been led to the sure hope that under your gracious rule the nation will continue to hold the proud position which it has gained under the guidance of your beloved mother.

That your Majesty's reign may be long, happy, and glorious, and that you may ever rule in the hearts as well as over the persons of a loving, dutiful, and grateful people is the earnest wish and ardent prayer of your Majesty's loyal and dutiful subjects, the President, Council, and Fellows of the Royal Society of London.

The King's reply was as follows :—

I am much gratified by the warm expression of your loyalty and affection, of your profound sympathy with our present grief, and of your loving appreciation of the goodness and great qualities of my dearly beloved mother. I thank you for your dutiful good wishes, and I share your hope that my reign also may be blessed by a continuous growth of my people in enlightenment, refinement, and power for good. The intellectual attainments and energies which your society so conspicuously represents are among the most precious possessions of the nation as aids in securing those high ends, and I remember with gratification the close connection of the society with its Royal founder and my other predecessors on this Throne, and the fact that I am a Fellow, as was also my dear father. You may feel assured of my constant interest in and protection of your work, and in token of my good will I shall be pleased to inscribe my name as patron in the charter book.

NOTES.

WE deeply regret to announce that Prof. G. F. Fitzgerald, F.R.S., died on Thursday, February 21, at the age of forty-nine years.

SIR ARCHIBALD GEIKIE retires to-day, February 28, from the office of Director-General of the Geological Survey of the United Kingdom and Director of the Geological Museum, after a service of nearly forty-six years. He has remained at his post after the usual age-limit in order to complete the annual summary of progress of the institution under his charge. It is understood that, being now freed from administrative duties, he intends to devote himself to the completion of several important Memoirs of the Geological Survey. He is succeeded in his appointment by his colleague, Mr. J. J. H. Teall, F.R.S., who is at present president of the Geological Society.

A VERY interesting announcement referring to the Leonid meteors has been received from the president of the Toronto Astronomical Society. He informs us that Mr. R. F. Stupart, vice-president of the Society, director of the Toronto Observatory and superintendent of the Meteorological Service of Canada, has sent him a copy of the following notes made by an observer at York Factory, Hudson's Bay :—"November 15, 1900. Very general display of shooting stars. Some very big ones N.W. to S.E. Sky full in shoals. November 16.—Shooting stars seen until daylight. Scared the people—they thought it was the end of the world." From these records it appears that a shower of Leonid meteors actually did occur last November.

IT is announced that a strong and influential committee has been formed with a view of erecting a triple monument in Heidelberg, by which the names of Bunsen, Kirchhoff and Helmholtz, whose lives and works are inseparably associated with the scientific progress and the rapid social and intellectual development of the alma mater of that city, should be thus lastingly and fittingly commemorated. It is proposed that special appeals for contributions should shortly be issued to some of the learned societies and academies in the German Empire as well as to some personal friends and admirers of the late three famous men of science, whose friendship they are known to have enjoyed and by whose influence they have benefited in their subsequent scientific attainments. It is understood, however, that the general public will not be invited to contribute towards this Bunsen-Kirchhoff-Helmholtz memorial fund. The chairman of the committee is Dr. Adolf Kussmaul, Emeritus Professor of Medicine in the University of Strassburg, to whose suggestion the movement owes its origin.

THE current issue of the *Journal* of the Franklin Institute contains an interesting account of a discussion on the electric distribution of power in workshops, which brings out very clearly the numerous advantages to be gained by the adoption of this method of distributing power. The rapid success which the system has achieved in America points conclusively to its convenience and economy. As one of the speakers pointed out, electric power originally based its claim to attention on the ground that there was much less loss in distribution, and that a saving of 20 to 60 per cent. of the total power used might therefore be effected by substituting electric for shaft driving. This saving, although at first sight it appears great, may, however, be quite small when considered in relation to the total cost of turning out the finished article which the factory produces, amounting, perhaps, to but a small fraction of a per cent. But electric power, it was soon found, effects saving in many other ways, one of the chief of which is that it enables the positions of machinery to be decided with reference to the machine rather than to the shafting. This means that the available floor space can be much more thoroughly utilised. In the case of the Baldwin Locomotive Works, it was stated in the discussion, the adoption of electric driving has saved so much floor space that the works would have to be made about half as big again to give the same output with shaft driving. In addition to these advantages, electric power has proved more convenient, healthier and less dangerous. With all these recommendations it ought not to be long before it entirely displaces the old-fashioned systems.

A BILL intended to organise the National Observatory of the United States has been introduced into the Senate by Mr. Morgan. The object is to convert the U. S. Naval Observatory into a National Observatory, and the following sections from the text of the bill, given in *Science*, describe the proposed organisation :—"That the Director of the National Observatory shall be an eminent astronomer, appointed by the President, by and with the advice and consent of the Senate, at a salary of five thousand dollars per annum, and shall be selected from the astronomers of the National Academy of Sciences unless, in the judgment of the President, an American astronomer of higher scientific and executive qualifications shall be found. That the Secretary of the Navy may detail for duty as astronomers at the National Observatory such professors of mathematics and other officers of the Navy as he shall deem necessary in the interests of the public service ; but on and after the passage of this Act no appointments shall be made of such professors unless required for service at the Naval Academy."

THE departmental committee appointed by the Board of Agriculture, and presided over by the Earl of Onslow, to inquire into the conditions under which agricultural seeds are at present sold, has completed the report upon the subject. The committee conclude that the seed trade in England is, on the whole, well conducted, and has of late years improved with the advance of science. Nevertheless, the majority of the committee recommend that one central station should be provided in the United Kingdom for the purpose of testing the purity and germinating power of seeds sent to it for official examination.

THE Berlin correspondent of the *Times* gives some of the results of the German census of December, 1900, which have just been published. The population of the German Empire has increased from 52,279,901 in 1895 to 56,345,014. Of this population 27,731,067 are males and 28,613,947 females. Over 83 per cent. of the whole population is contained in the four kingdoms; of these Prussia comes first with (in round figures) 34,500,000 inhabitants, and Bavaria second with 6,200,000. The figures for Saxony and Württemberg are 4,200,000 and 2,300,000 respectively. More than 16 per cent. of the population is resident in the thirty-three towns of over 100,000 inhabitants. Of these thirty-three towns the largest is Berlin, with a population of 1,884,151.

A REUTER telegram from Calcutta states that at a meeting of planters and agents interested in the indigo trade, held on February 20, it was decided to appoint a committee to wait on the Lieutenant-Governor in order to request him to grant a subsidy for further researches, as the results reported by the experts, Messrs. Hancock and Rawson, were highly promising. In the course of the meeting Mr. Karpeles said that Dr. Brunck's advice to Indian planters to give up the indigo trade was not likely to be followed. No reduction in planting was contemplated, and an increased output was expected from the manuring and blower processes.

AT the Wilts County Council's meeting on Friday last, reference was made to the fall of stones at Stonehenge, and a discussion ensued as to the taking of steps for the preservation of the remains. Prof. Story Maskelyne suggested the appointment of a small committee, not necessarily composed entirely of members of the council, but Lord Edmund Fitzmaurice, M.P. (the chairman of the council), explained that the matter was already being dealt with by the Charities and Records Committee, to whom the question of ancient monuments had been referred. It was also stated that the committee was in communication with the landowner and with the Society of Antiquaries, and hoped to report definitely at the next meeting.

WE have to regret the death, on February 15, at twenty-six years of age, of Mr. Fred. Pullar, son of Mr. L. Pullar of Bridge of Allan. In conjunction with Sir John Murray he had recently published an admirable survey of the depths of many Scottish freshwater lochs, illustrated with beautifully engraved charts. The manner of his death was heroic. While skating on Airthrey Loch, near Bridge of Allan, a young lady fell through the ice, and he at once skated to her assistance and plunged in with his skates on. He kept her afloat for ten minutes, but in spite of determined efforts to save them, both perished. Eye-witnesses testify that he might have saved himself but for his devotion to duty. He was an only son, and the warmest sympathy is felt and expressed for his family.

THE Reale Istituto Lombardo has made the following awards of prizes:—Under the Brambilla foundation for improvements in industries or manufactures in Lombardy, a gold medal and 1000 lire to Gadda and Co., of Milan, for electrical machinery; a gold medal and 500 lire to Reiser, Cattoretti, Gola, Norsa and Co., for their manufacture of embroidery with new shuttle machinery; and the same to Carlo Fino for the preparation of cattle food in which blood and molasses are used; and a premium of 300 lire to Virginio Rimoldi for machinery for sewing gloves. Under the Fossati foundation a prize of 2000 lire has been awarded to Prof. A. Stefani for his papers on the regeneration of the peripheric nervous fibres. A number of other prizes remain unawarded. The prizes now offered include a prize of the Institution for the best essay on the differential equations of applied electricity to be sent in by April 1, 1901; a similar prize for 1902 for a toponomastic exploration of a district of Lombardy; two triennial medals for agricultural and industrial improvements in Lombardy; a Cagnola prize and gold medal for the best report dealing with hailstorms on the two sides of the Alpine chain, due April 1901; and a similar prize and medal for 1902, for an essay on the effects of gaseous emanations from manufactories on cultivated plants; another Cagnola prize for a discovery dealing with the cure of pellagra, the nature of miasms and contagion, the direction of balloons, or the prevention of forgery; a Brambilla prize for industrial improvements in Lombardy; Fossati prizes for 1901 and 1902 for essays on the anatomy of the encephalus of the higher animals; and for 1903, on the so-called nuclei of origin and termination of cranial nerves; a Kramer prize awarded to Italian engineers; a Secco-Comneno prize on the Italian phosphatic deposits; a Zanetti prize, open to Italian pharmaceutical chemists; and Pizzamiglio and Ciani prizes for educational and literary writings.

A CIRCULAR letter has been sent out seeking an expression of opinion from experts as to the advisability of founding a journal for the statistical study of biological problems. The letter is signed by Profs. Karl Pearson and Weldon, pioneers in this country in the line of work it is desired to encourage. *Biometrika* is the proposed title of the journal; thirty shillings the estimated cost of the first volume, to consist of four parts; and the proffered programme is an embodiment of memoirs on variation, inheritance and selection based on statistical examination, the development of statistical theory as applied to biological problems, and abstracts of memoirs on these subjects appearing elsewhere in each of the four leading European tongues. The proposal to found this journal is a natural sequel to the appearance during the last few years of the *Archiv f. Entwicklungs Mechanik* and, later, of the *American Journal of Physiology*, so largely devoted to the work of experiment on the living organism. The founders claim for statistical inquiry into biological phenomena a now established position, and give it as their opinion that "many persons are deterred from the collection of such data by the difficulty of finding such a means of publishing their results as this journal would afford." Statistical work in biology, to be of service, must be far-reaching and extensive, and it cannot be well dissociated from morphological inquiry of the better kind. A mere shot here and there at a miscellaneous collection of objects will not suffice now that the experimental stage has been passed, but upon prolonged work of an order involving laborious investigation with a fixed purpose, often with extended experiment, to be made, when possible, over a large area, can reliance alone be placed. Progress must necessarily be slow, and the accumulation of results worth publishing can only be expected after protracted research; and in these circumstances we are doubtful if the desire to burden the already over-crowded literature of biology with a new serial is not somewhat premature. It may be borne in mind that existing periodicals and the organs of societies are available for purposes of publication; and we could well desire for some of these that much of the so-called "systematic" work and quibbling over priority in nomenclature, fast becoming intolerable, might be replaced in work of the statistical and experimental order.

MR. W. A. HICKMAN, New Brunswick Government Commissioner, delivered a lecture on "New Brunswick" at the Imperial Institute on Monday. Like the rest of the maritime provinces of Canada, New Brunswick is situated much nearer Great Britain than any other of the important food-producing areas of the Empire. St. John, the capital, situated at the head of the Bay of Fundy, is the chief winter port of Canada, and the first lumber-shipping port in the world. The province contains 10,000,000 acres covered with heavy forests valuable

for lumber or wood pulp. The manufacture of this pulp from spruce is an industry yet in its infancy, only a few mills being in operation. The demand for the product for paper-making is practically unlimited, and the supply in New Brunswick very great, while the transport facilities of the province for shipment either to British or Eastern American ports are excellent. In 1891 there were no Government-supervised butter and cheese factories, now there are about 100; in 1895 there were no modern roller wheat mills, in 1900 about 80,000 barrels of flour were manufactured. The dykelands round the Bay of Fundy are the most fertile agricultural lands in the temperate zone, and perfectly self-sustaining; as also is the majority of the land situated along the shores of the rivers and lakes.

THE difficulties involved in the manipulation of a long celluloid film have prevented the extensive use of kinematographic apparatus by amateur photographers. To avoid this objection, Mr. Leo Kamm has invented a camera—the Kammatograph—in which a circular glass plate takes the place of the celluloid film. The plate can be made to rotate rapidly by means of a multiplying gear, and at the same time it travels laterally. A small lens forms an image upon the plate, and when the plate is put in motion these images are multiplied into a series of pictures arranged in a spiral. The character of the pictures and their distribution will be understood from the accompanying reproduction of a small part of a series produced in this way. The plate

is, of course, developed precisely in the same way as an ordinary negative, and a positive is then taken from it. To display the series of pictures it is only necessary to place the positive in the camera and to arrange the camera so that the beam from a lantern close to it can pass through the lens. The plate is then rotated as before, and the succession of the pictures projected upon the screen reproduces the original movements. About six hundred pictures can be photographed during the motion of a single plate, at a rate of about twelve or fourteen a second. The camera is very compact, and both as regards price and adaptability is within the reach of any photographer who wishes to secure pictures of rapidly changing scenes and moving objects. The small size of the pictures will not permit of projection upon a large screen, but the views can be shown large enough for ordinary purposes.

FROM the point of view of public health, it is undesirable to cut up open spaces used for recreation near large cities. The Commons and Footpaths Preservation Society directs attention to the fact that there are several private bills, now before Parliament, which propose to take power to interfere with commons, village greens and open spaces. The City and North-East Suburban Electric Railway will seriously affect Hackney Marshes and Leyton Marshes, and, in a lesser degree, Victoria Park. The line is to be for the most part in tunnel, but where it crosses Hackney Marshes and Leyton Marshes, two exceptionally valuable open spaces, it will emerge from the tunnels and run on an embankment varying from 5 feet to 20 feet in height. Two short branch lines will also be erected on the surface of the Marshes, and altogether about twenty-five acres of common land will be abstracted. The North-East London Railway also seek powers to run a line on an embankment, varying from 14 to 31 feet in height, over Walthamstow and Leyton Marshes. The construction of more than two miles of high embankments on a much-used and highly valuable stretch of common land would practically destroy its utility as an open space and injure its amenity. The Society has therefore resolved to oppose the bills.

WE learn from the *Scientific American* that the Niagara Falls Power Company has about completed its second power transmission line between Niagara Falls and Buffalo. The new line possesses special interest because of the fact that the cables are made of aluminium. The three-phase current is transmitted by three cables, each composed of thirty-seven strands. The old line consists of six copper cables, each of which has nineteen strands. One advantage gained in the use of aluminium is that the cables being so much lighter, the span between poles, which in the old line is about 75 feet, averages 112½ feet in the new line. On the completion of the aluminium line, the voltage of the current that is transmitted will be raised from 11,000 to 22,000 volts.

WE have received from Mr. R. F. Stupart, director, a copy of the Report of the Meteorological Service of Canada for the year 1897, a large quarto volume of 292 pages. Observations were made at 314 stations; at the chief stations, where all the ordinary observations are taken day and night at equal intervals of time not exceeding four hours, at the telegraphic reporting stations, where the observations are taken three times daily, and at some few of the special stations, the observers are paid for the time which they devote to the duties required of them, but at the bulk of the stations the work is purely voluntary, the Meteorological Department at Toronto simply supplying the necessary instruments. A liberal exchange of telegraphic reports takes place between the United States and Canada, from which data a very comprehensive daily weather chart is constructed and on the basis of these charts forecasts and storm-warning notices are issued. The storm warnings are very successful, about 86 per cent. being fully verified, while the direction from which the wind would blow was fully verified, to the extent of about 94 per cent. The daily forecasts obtain an average success of 81 per cent. They are disseminated to the agricultural community by discs on the baggage vans of outgoing morning trains. The tables of observations and results are very carefully prepared, and the whole report furnishes an important contribution to climatological knowledge.

THE Society for the Protection of Birds has issued a small pamphlet, by Surgeon-General Bidie, urging the need of effective protection for wild birds in India.

TWO numbers (18 and 19) of the *Circular* of the Royal Botanic Gardens, Ceylon, have reached us; the one giving a list of the kinds of ornamental and timber trees best suited for planting in the island, and the other describing certain caterpillars which infest the tea-plant.

MUCH interest attaches to Mr. J. P. Smith's account, in the *American Naturalist*, of the coiled larval shell found attached to the lower extremity of many specimens of Baculites from the Cretaceous beds of Dakota. This straight-shelled Cretaceous

cephalopod is accordingly considered to be descended from a coiled Clymenia-like ancestor.

WE have received the *South-Eastern Naturalist* for 1900. In addition to several papers, it contains an account of the congress of the South-Eastern Union of Scientific Societies, held at Brighton in June under the presidency of Prof. Howes. Bird protection was one of the subjects discussed, in connection with which the president expressed his opinion that the present unsatisfactory state of affairs is largely due to the apathy of local authorities in putting enactments in force.

THE systematic position of the sand-grouse forms the subject of a paper, by Dr. R. W. Shufeldt, in the January number of the *American Naturalist*. It is concluded that these birds form a subordinal group intermediate between the pigeons and the game-birds. In the same serial Mr. G. H. Parker discusses certain tortoises with abnormally formed horny shields, in which correlated abnormalities likewise occur in the underlying bony plates. And he is led from this association to conclude that in the primitive chelonians each plate was covered by its own proper shield, as in the case of the glyptodons of South America.

To the February number of the *Zoologist* Mr. G. Renshaw contributes an account of all the known specimens, whether alive or dead, by which the quagga has been or is represented in menageries or museums. About ten living examples of this extinct equine appear to have been exhibited from time to time in menageries. Three skins, a skeleton, and two skulls represent the animal in the United Kingdom, in addition to which two other skeletons have been stated to be those of quaggas. Continental museums are more fortunate, possessing among them, in addition to several skeletons and skulls, no less than eleven mounted skins, one of which is that of a fœtus. In the South African Museum this once abundant species is represented only by a foal. A skeleton at Philadelphia, said to be that of a quagga, completes the list of known remains. The author states his belief that the skin and skeleton in the British Museum belong to an individual which died in the Zoological Gardens previous to 1838, in reality they were not acquired till 1864.

IN the *Journal de Physique* for January, M. E. Mathias applies Weierstrass's signs to determine the mutual induction of two parallel circular currents. The advantage of this method is that it enables the potential energy to be expressed as a function of the radii and distance apart of the circuits in a rapidly converging series.

MR. GILBERT NEWTON LEWIS suggests a new conception of thermal pressure and a theory of solutions in the *Proceedings* of the American Academy (xxxvi. 9). The theory, according to which the thermal pressure of any phase is equal to the pressure which the substance would exert if under the same conditions as a perfect gas, suggested itself in the consideration of certain remarkable general laws which treat of heterogeneous equilibrium in which the several phases are subject to different pressures. The same assumption is alone sufficient, according to the author, to explain all the laws of dilute solutions. The relations of Mr. Lewis's theory to the theory of van der Waals are also discussed.

THE January number of *La Géographie* contains a paper by Dr. A. G. Nathorst, of Stockholm, on the distribution of the wolf and the musk-ox in high northern latitudes, and especially in Eastern Greenland. Count Henri de la Vaulx contributes a paper on his journeys in Patagonia.

THE new number of the *Mitteilungen aus den deutschen Schutzgebieten* is devoted to an account of the work of the German members of the British and German Boundary Commission between Lakes Nyasa and Tanganyika. There are special reports, on the astronomical and geodetic work, by Dr. E. Kohlschütter, and on the country and people, by Captain Herrmann. Four sheets of an excellent map on a scale of 1 : 100,000, by the members named and Lieut. Glauning, accompany the reports.

THE Eighth Annual Report (for 1899) of Dr. S. Calvin, the State Geologist, forms vol. x. of the Iowa Geological Survey. It contains a useful index geological map of the State; a report on the mineral production, which includes coal, clay, stone, gypsum, and lead, zinc and iron ores; and sundry geological reports. Mr. Stuart Weller deals with the succession of fossil faunas in the Kinderhook Beds at Burlington. These faunas exhibit a gradual transition from those with Devonian to those with Carboniferous characters. The Devonian element is for the most part exhibited by the pelecypods, while the brachiopods ars usually Carboniferous in aspect, and there is an overlapping and intermingling of these forms. The geological reports deal very fully with different counties in Iowa.

IN the *Proceedings* of the Liverpool Geological Society (vol. viii. part iv., 1900) we find an interesting address by Prof. W. A. Herdman on "The Geological Succession of Morphological Ideals." Referring to the many distinct groups of animal life found in the Lower Cambrian rocks, and which are usually taken to indicate that "we are already pretty far up in the history of evolution, and very far in time from the primitive fauna," he expresses the opinion "that the first differentiation of the great groups of invertebrates may have taken place very rapidly in pre-Cambrian times at the surface of the sea amongst soft-bodied pelagic animals." He then discusses the chief faunas of the Palæozoic rocks, pointing out the successive organic types which dominate as "representatives of the ideals which Nature seemed striving to attain in the successive geological periods."

THE observatory on Mount Etna, being situated at a height of 2950 metres, at the foot of the central crater and only 300 metres below the summit, it has been assumed that the ground on which it is built must be almost continually in a state of tremor. To show how unfounded the supposition is, Messrs. A. Riccò and L. Franco have made a comparative study of the tromometric records from the observatory there and from that at Catania, the instrument employed being the normal tromometer $1\frac{1}{2}$ metres long, and the readings being taken six times a day for nearly eight years. In 46 per cent. of the observations on Etna, and in 62 per cent. of those at Catania, the tromometer was found to be in motion. The higher figure at Catania is partly due to the influence of external agents; for, when the sea is rough, the tromometer there is never still, while on the mountain it is unaffected. Also, taking only those observations made when the wind was strong, or very strong, the tromometer on Etna was in motion in 59 per cent. of all such cases, and that at Catania in 94 per cent. On the other hand, when there was little or no wind and the sea was nearly, or quite, smooth, the corresponding figures are 38 for Etna and 69 for Catania.

THE fifth part of "Zoological Results based on Material from New Britain, New Guinea, Loyalty Islands and Elsewhere, collected during the years 1895–1897," by Dr. Arthur Willey, has been published by the Cambridge University Press. The work will be brought to a conclusion by the publication of one other part in the course of the present year, and when it appears the six parts will be reviewed together.

THREE new volumes in Ostwald's series of "Klassiker der exakten Wissenschaften," published by Mr. Engelmann, Leipzig, have been received. No. 114 contains letters and other communications written by Volta in 1792–1795 upon the subject

of animal electricity, and No. 118 contains Volta's accounts of investigations made by him in the period 1796–1800. No. 115 is devoted to de Saussure's research in hygrometry (1783). The three volumes are edited by Dr. A. J. von Oettingen, and are in German, like the other volumes in the series.

An interesting synthesis of fumaric acid is given in the current number of the *Berichte* by O. Doebner. Under the action of pyridine, condensation between glyoxylic and malonic acids is readily effected. The condensation may be imagined to take place with the intermediate formation of maleic acid, but attempts to isolate this were unsuccessful.

In his account last year of the properties of the remarkable hexafluoride of sulphur, M. Moissan mentioned that other bodies were formed at the same time containing sulphur and fluorine, and in the current number of the *Comptes rendus* he gives, in conjunction with M. Lebeau, a further contribution to this subject. The compound described is sulphuryl fluoride, SO_2F_2, and it is obtained by the regulated action of fluorine upon sulphur dioxide. The conditions of the reaction had to be carefully studied, as the reaction of these two gases is so violent that explosions frequently occur. The new gas is necessarily accompanied by others, owing to the operations being carried out in glass vessels, and the separation of these is effected by liquefying the whole at $-80°$ C. and fractionating *in vacuo*. Sulphuryl fluoride is a colourless, odourless gas, solidifying in boiling oxygen, melting at $-120°$ C., and boiling at $-52°$ C. Although in some respects it resembles its halogen homologues, in its stability and inertness in other reactions it recalls the properties of the hexafluoride. Thus it is without action upon water even in a sealed tube at 150° C. M. Moissan remarks that these experiments show that although fluorine is undoubtedly at the head of the halogen group, it is a little removed from the others, having special and characteristic properties which show affinities rather to oxygen than to chlorine.

The additions to the Zoological Society's Gardens during the past week include a Patas Monkey (*Cercopithecus patas*), a Green Monkey (*Cercopithecus callitrichus*), an Anubis Baboon (*Cynocephalus anubis*), an African Civet Cat (*Viverra civetta*), a Denham's Bustard (*Eupodotis denhami*), a Royal Python (*Python regius*) from Falaba, Sierra Leone, presented by Mr. C. E. Birch; two White-collared Mangabeys (*Cercocebus collaris*), a Bay Duiker (*Cephalophus dorsalis*) from West Africa, presented by Mr. E. R. Cookson; a Herring Gull (*Larus argentatus*), European, presented by Mr. C. A. Hamond; a Jay (*Garrulus glandarius*), a Jackdaw (*Corvus monedula*), European, presented by Miss N. Eskell; a Merlin (*Falco oesalon*), European, presented by Mr. Gregory Haines; a Goshawk (*Astur palumbarius*), European, presented by Major-General A. A. Kinloch, C.B.; a Barn Owl (*Strix flammea*), European, presented by Mr. A. Masters; two Dwarf Chameleons (*Chamoeleon pumilus*) from South Africa, an Axis Deer (*Cervus axis*) from India, deposited; a Hoffmann's Sloth (*Cholopus hoffmanni*) from Panama, a Great Ant-eater (*Myrmecophaga jubata*) from South America, two Horned Tragopans (*Ceriornis satyra*) from the South-east Himalayas, four Californian Quails (*Callipepla californica*) from California, four Virginian Colins (*Ortyx virginianus*) from North America, purchased.

OUR ASTRONOMICAL COLUMN.

Astronomical Occurrences in March.

March 2. 10h. 46m. to 12h. 3m. Moon occults κ Cancri, (mag. 5·0).
6. Outer minor axis of Saturn's ring = 15″·24.
7. 13h. 3m. Minimum of Algol (β Persei).
9. Mars in conjunction with α Leonis (Regulus), Mars 3° 49′ North.
10. 9h. 52m. Minimum of Algol (β Persei).
11. Saturn in conjunction with π Sagittarii (mag. 3·0). Saturn 1° South.
13. 6h. 41m. Minimum of Algol (β Persei).
14. 11h. Jupiter in conjunction with the moon. Jupiter 3° 25′ South.
14. 21. Saturn in conjunction with the moon. Saturn 3° 26′ South.
15. Venus. Illuminated portion of disc = 0·980.
15. Mars. Illuminated portion of disc = 0·979.
24. 7h. 37m. to 8h. 40m. Moon occults ω^1 Tauri (mag. 5·8).
25. 6h. 32m. to 7h. 42m. Moon occults l Taur (mag. 5·5).
26. 9h. 15m. to 10h. 6m. Moon occults 68 Orionis. (mag. 5·6).
28. 6h. 16m. to 6h. 40m. Moon occults 1 Cancri (mag. 5·9).
29. 5h. 30m. to 6h. 33m. Moon occults A^2 Cancri (mag. 5·8).

Variability of Eros.—The recent announcement by Dr. Oppolzer concerning the variation in the brightness of the minor planet Eros is confirmed by the accounts of two French observers, who communicate their results in the current issue of *Comptes rendus* (vol. cxxxii. pp. 396–398).

The first paper, by M. F. Rossard, describes a series of determinations made at the observatory of Toulouse with a Brunner equatorial of 0·23 metre aperture. Estimates with comparison stars were taken on the nights of February 14, 15, 16 at short intervals. Evidence of rapid variation was detected, the difference exceeding a magnitude, the extreme range being from 9·3 to 11·0. The times of the various phases observed were as follows:—

		h. m.				h. m.	
1901 Feb.	14	9 43	min.	1901 Feb.	16	7 34	max.
	14	10 48	max.		16	8 56	min.
	15	8 10	max.		16	10 3	max.
	15	9 32	min.		16	11 30	min.
	15	10 44	max.				

The comparison of these minima and maxima indicates that the variation in brightness shows a little less than ten periods in a day, *i.e.* the duration of the period is about 2h. 22m.; also that the period of increase from minimum to maximum is about 15 minutes shorter than the interval from maximum to the following minimum.

The second note is by M. Ch. André. He says the total variation takes place in about 6 hours, and in character is similar to the variable star U Pegasi, but with the stationary period a little longer, so that the planet Eros is to be regarded as a photometric variable, and may consist of a double system formed of two asteroids, whose diameters are slightly less than 3 : 2, and whose orbital plane passes through the earth. As the distance of Eros from the earth is about two-thirds that of the sun, the inclination of the line of sight on the plane of the orbit will change rapidly and continuously. The study of these variations will be important in giving a series of light curves, in which the only variation is that of the inclination of the line of sight on the plane of the orbit of the satellite.

New Variable Star, 1. 1901 (Cygni).—Mr. Stanley Williams announces the variability of the star situated in the position

$$\left.\begin{array}{l}\text{RA.} = \overset{\text{h.}}{19}\ \overset{\text{m.}}{28}\ \overset{\text{s.}}{1\cdot5} \\ \text{Decl.} = +28°\ 0'\cdot5\end{array}\right\}(1855).$$

The estimated photographic magnitude varied as follows:—

		Mag.
1900 Oct. 27	...	10·7
Nov. 18	...	9·9
Dec. 15	...	10·5

A chart of the region surrounding the star is given, and reference made to a previously published photograph of the region by Dr. Max Wolf (*Knowledge*, 1892, p. 130), on which the star is not shown. (*Astronomische Nachrichten*, Bd. 154, No. 3687).

RECENT WORK OF THE INDIAN MARINE SURVEY.[1]

THE importance of the work intrusted to the Indian Marine Survey, alike from the point of view of the hydrographer, of the geologist, and of the zoologist, is so well known to all men of science that it would be mere waste of time to attempt to emphasise it on the present occasion. All the Reports that have from time to time been published by this Survey bear witness to the zeal and energy with which the work is carried on—frequently under circumstances of great difficulty—and to the capacity and accomplishments of the officers to whom it is entrusted. But it will be no reflection on previous documents of the same nature if we call attention to the special interest attaching to the one now before us, on account of the varied nature of the subjects on which it touches, the philosophical manner in which these are treated, and the problems presented by many of them.

The first section of the Report is by Commander T. H. Heming, R.N., who has entire charge of the Survey; and geologists will read with great interest his account of the rapid silting-up of the Gulf of Martaban that is now in progress. It appears that an enormous quantity of sediment is being carried into the Gulf by the Salween River; a sample of water taken at spring tide during the dry season yielding no less than 1/300th of dry mud by weight. The deposit has mainly taken place outside the 10-fathom line, and so heavy is it that in spots where there were formerly from 40 to 50 fathoms, the depth is now reduced to from 15 to 20; the area affected being approximately 2000 square miles. "Putting the amount of water discharged by the river flowing into the Gulf at a low estimate," says the Report, "and supposing it capable of supporting on the average one-quarter of the proportion of sediment held in solution [? suspension] by the specimen examined, there would be more than enough solid matter carried into the Gulf in forty years to cause the silting-up which has actually taken place."

Another point of interest in this section is the longitude of the Andamans, which, as deduced by running a meridian distance to Sugar-loaf Island, was found to differ by 1′ 70″ from that given by the Great Trigonometrical Survey. In consequence of this discrepancy it is now proposed to run a meridian distance between Port Blair and Diamond Island both ways, in order to obtain the best possible results with the means at disposal.

Passing on to the section of the Report written by the Surgeon-Naturalist, Captain A. R. S. Anderson, we may call attention to the remark as to the rapid change in the coloration and appearance of the animals of Ford Bay, Great Cocos Island, when the coral bottom of the open channel is left for the sandy bottom of the bay. While quarantined off Colombo a lucky haul brought up no less than forty-one examples of the rare crustacean *Lupocyclus orientalis*, of which only three specimens were previously known to science. In another haul, which brought up a miscellaneous collection of dead corals, sharks' teeth, fish-bones and bones of turtles, the interesting fact was discovered that while some of these were in practically the same condition as at the time of their deposition, others had been highly impregnated with mineral matter. No embedding in sediment had, however, preceded the fossilisation (if the term is permissible in this connection), which had evidently taken place as the bones lay loose on the sea-bottom.

In a haul taken some distance east of the Maldives, Captain Anderson was fortunate enough to procure over 200 specimens of an echinoderm nearly related to the West Indian *Palaeopneustes hystrix*, but apparently specifically distinct. When placed in spirit these urchins turned it a magnificent rich purple, although their own colour was a dull madder-brown. Many other rare and interesting invertebrates were obtained at other dredging stations, but we must omit mention of any of these to refer to a totally different subject.

Between Colombo and Rangoon an excellent opportunity was afforded of carefully observing the flight of the common flying-fish (*Exocoetus evolans*). "When they first rise from the water," writes the narrator, "they do so with a very rapid fluttering of their wings lasting for two to three seconds; they then soar along till their speed is so reduced that they descend and touch the water, into which they either fall with a splash or dip the elongated tip of the caudal fin, and, I think, the ventral fins on which they seem to poise themselves, again rapidly vibrate their wings, and get up sufficient speed to renew their flight; this process I have seen them repeat as often as seven times in the course of one long flight. Very occasionally, however, I have observed these fish fluttering their wings without touching the water with their caudal and ventral fins."

After mentioning that in order to observe these motions calm weather and a binocular are necessary, Captain Anderson proceeds to say that he fails to understand how Moseley, as narrated in his "Naturalist on the *Challenger*," as well as several other observers, have denied the fluttering of the wings in flying-fish. Apparently he is unaware that it has been stated in the "Royal Natural History" by the editor, as the result of personal observation, that these fish do possess the power in question, as indeed had been attested in *Land and Water* by a much earlier observer. Captain Anderson's observations also corroborate the statement made by the writer last referred to, that flying-fish are capable of altering the direction of their flight: an attribute that was denied to them by Dr. Möbius in his well-known account.

In a later paragraph Captain Anderson draws attention to the circumstance that in flying-fish the lower surface of the body is flattened in order to enable them the more easily to rise from and hover over the water, and that in the allied genus, Hemirhamphus,[1] the members of which rush at full speed along the top of the water with only the hinder portion of the body immersed, a similar flattening is observable.

While lying in Burmese waters off Moulmein, the surveying vessel encountered a large quantity of drift-wood brought down by the Moulmein river. Some of this became entangled in the paddle-wheels, and on three mornings snakes were found on the floats. A female leopard, probably carried down by the strong tide, took refuge one morning on a cargo boat moored somewhat higher up, and eventually swam ashore, where she was shot. These instances are of much interest in connection with the dispersal of species.

Much of the latter portion of this section of the Report is occupied by an account of the author's experiences in the Andaman Islands, where he has much to say concerning both the natives and the fauna. In one passage he mentions that, while walking through the forest, a native announced the presence of a large mass of wild honey in the immediate neighbourhood, which he detected by its smell, although this was quite imperceptible to the European members of the party.

In conclusion, Captain Anderson refers to the remarkable circumstance that in the neighbourhood of the Andamans there occur masses of sandstone at a depth of between 39 and 226 fathoms which are quite bare of coral, although there is an abundant growth of the same in the immediate neighbourhood. It is inferred that the bare area, and probably also the larger portion of the bank, has never been within the zone of massive reef-building corals. "Had it ever been so, it is most improbable that there should be bare rock exposed at 39 fathoms. For that the bank is eminently suitable for the growth of coral, both the dredgings and the soundings, by bringing up live coral, showed; at no part of the bank was there any turbidity of the water sufficient to check coral-growth. . . . Were the theory correct that, given a bank rising within a comparatively short distance of the surface, deposit will accumulate on that bank and so form a basis for a coral island, there is no reason why, in the case of this bank, bare rock without any such deposit on it should be found."

Many other equally interesting and suggestive extracts might be culled from this valuable report did limitations of space permit.

R. L.

[1] Administration Report of the Marine Survey of India for the Official Year 1898–99. Pp. 17. (Bombay: Government Central Press, 1900.)

[1] A mis-spelling of this and several other names is noticeable in the Report, but, as the writer of this notice is well aware, much allowance must be made for an author whose copy is set up by native Indian printers.

THE TEACHING OF PHYSIOLOGY.

IT is scarcely too much to say that the only real scientific knowledge is that obtained through personal experience. Lectures and text-books have their places in a scheme of instruction in science, but they only convey information at second-hand, whereas original experimental work creates and fosters the inquiring spirit characteristic of a progressive mind. What students need to be taught is that they must be not so much receptive as constructive; and the way to give force to this view is to insist upon their taking an active share in investigation at

every stage of their careers. It is in the highest degree satisfactory to know that this principle is being acted upon in the courses of scientific instruction followed in many of our schools and colleges—more particularly in the Schools of Science and Higher Elementary Schools of the Board of Education. But a large class of students of a higher grade are introduced to scientific subjects on the old-fashioned plan, the reason in most cases being that they have no time to pursue a course of work constructed on rational lines. Metaphorically, they endeavour to enter the field of science by a short cut instead of following the route of patient and persistent observation, and in the end they find themselves without the certificate of admittance into the Delectable City. Medical students are the greatest sinners in this respect, but the fault lies not so much with them as with their masters and examiners. So many subjects have to be taken that it seems almost hopeless to look for greater opportunity for investigation or for the development of a spirit of research in students whose knowledge of practical chemistry is obtained by a few hours' test-tubing. In the teaching of physiology, also, there is a great gap between rational methods and existing practice, and Dr. W. T. Porter, associate professor of physiology in the Harvard Medical School, directs attention to it in an article which we reprint, slightly abridged, from the special educational number of the *Philadelphia Medical Journal*. Dr. Porter shows, in addition, how large classes of students may be carried along the well-known roads that lead to scientific power, and gives the results of one year's experience with a method of instruction different from that usually employed. His paper thus contains a statement of a course which has been proved to be practicable, and has been accepted by the Faculty of the Harvard Medical School. The methods described need not, however, be limited to medical education, as they are based upon principles which, *mutatis mutandis*, can be applied to instruction in any science. The paper is thus worthy of consideration by every one interested in the extension of natural knowledge.

———

To the physician the study of physiology is of use largely because it creates a habit of thought essential to the highest professional success. Physiology is a *rational* science. Its problems require the scientific method. They demand the precise statement of the question in hand, a severely critical examination of the results of experiments, and the arrangement of the accepted experiments in the order that shall lead logically, step by step, to a correct solution. Medicine is itself an experimental pursuit. Its higher walks are open only to those skilled in research. The scientific method cannot be acquired by the study of anatomy and pathology in the purely descriptive form in which they ordinarily are presented to the medical student; in this form they are stuff for visual and aural memory—not for the exercise of reason. Nor can the experimental state of mind be readily acquired by the study of clinical medicine. Reliance must be placed on a well-developed, highly rational science, cultivated to train rather than inform the mind, pursued, not for its stores of information, but for the highest product of human faculty—the system of inquiry that leads to light through darkness. Too often in our medical schools information is mistaken for knowledge. Only knowledge is power. The getting of mere information wastes the student's time. The vast accumulations of centuries of medical study confuse the undisciplined mind and crush the spirit. The burden of fact which any man can bear is relatively small, and each year grows relatively smaller. To find new truths and to look undismayed upon the old is the perfect fruit of education. This physiology can give, and on this power to train should rest the high position of physiology in schools of medicine.

The physiological lectures in medical schools are commonly given by one man and cover the entire field of physiology. This field is much too large to permit of even superficial personal acquaintance by one man. Necessarily, therefore, the instructor must take the chief part of his lecture from text-books. To this he adds citations of a few experiments or observations taken from the original sources. He has not and cannot have real knowledge as to the present state of special opinion on the majority of the chapters in his subject, because none but a specialist can cope with the constantly rising flood of meritorious research in any one chapter—to keep pace with the whole of a science which stretches ample arms over the larger part of human and comparative biology is impossible. Physiology could not be taught by the lectures now so largely given, even were lecturers gifted with superhuman knowledge. Physiology deals with phenomena, not with words. Many of these phenomena, for example the heart-sounds, cannot be described; others can be pictured dimly, but only to those who know related phenomena from having actually seen or otherwise sensed them; in no case can lectures properly instruct unless the fundamental facts or closely related facts have first been learned by actual observation in the laboratory. The student should come to the lecture already possessed by his own efforts of the phenomena to be discussed. Chapters, such as metabolism, in which the fundamental experiments are unusually difficult or protracted, should be preceded by less difficult though related chapters. If the obstacles to practical work in any field are insurmountable, the protocols of classical experiments in this field, together with a suitable connecting text, should be studied before the lecture. At present the lecturer too often merely offers a list of facts which mean little or nothing because they cannot be associated in the student's mind with phenomena already observed. The lecturer attempts to remind the student of that which the student never knew. The secondary schools have prepared the student to see nothing strange in this. Most men enter the physiological course persuaded that natural science can be acquired chiefly from books, and leave convinced that a deal of talk and a pennyworth of nature will give real knowledge of the action of living tissues.

A natural science cannot be well taught except by those who have themselves made experimental investigations in the special field which they would teach. No one in these days can work profitably in many fields, and only necessity should make one man attempt to teach them all. A man trained, for example, in the physiology of digestion is likely to have but a relatively feeble grasp on the physiology of the circulation, and nervous system, or the special senses. It follows that most of the instruction in the one-man system does not adequately represent the present state of knowledge. It is behind the times in all except the special field cultivated by the instructor himself. So far as possible, the didactic instruction in each field should be given by the member of the physiological staff actively at work therein, but this wise principle of the division of labour is not usually regarded.

Passing now to the demonstrations, we find that in the larger schools they are made before an audience of at least two hundred. Thus the greater number cannot see the demonstration clearly. If the class be divided into small sections, the brief glimpse allowed each man does not suffice for a full grasp of the details. Very commonly the demonstrations requiring much time are given in a course separate from the lectures. In short, most of the demonstrations as now given are an aid to the memory rather than a means of training in science. The position awarded them by the usual lecturer and by almost every student is one of the evidences of the fundamental pedagogical error which renders most medical teaching of anatomy and physiology so largely futile, namely, the deplorable notion that demonstrations are merely illustrative, and the book and the lecture the main force. Never was the pedagogical cart more squarely before the horse. Contact with nature is the essential of all training in biology.

The laboratory work in large schools is usually done in relatively small sections, and is not coordinated with the regular lecture course. The student feels that the experiments are purely secondary. The experiments are imperfectly arranged into groups. They merely illustrate the text-book. In no case do they present a full picture of any field. The time allowed is so short that criticism of results and insistence upon the proper standard of excellence is not attempted.

The instruction is the same to every student without regard to what his life is to be. Much time is given to matters which have a very remote connection with the future of most students, and which are not better material for training the mind than matter bearing directly on the student's future work.

It is important to inquire how this extraordinary system was developed. The reply is that the present method is a survival of mediæval methods; the student of tradition finds a rich field in the history of medical teaching. The teaching of physiology has broken away from anatomy; men now living have taught both subjects in the same course of lectures. Descriptive anatomy became the most conspicuous discipline in medicine at a time when the best mental training could be had only from books, from lectures, from abstractions. It was the flowering time of metaphysics, of authority, of the deductive method. The true principle of approaching nature discovered by the

Greeks survived only in a few men of genius, a spark that in our own time has been fanned into flame. Joined to the powerful example of the most liberal education of that period was the difficulty of obtaining material for dissection. Stark necessity united with specious theory to fasten upon this most concrete of sciences the methods of the schoolmen, and to this day the bulk of the instruction in anatomy remains didactic, and consists of books, diagrams, and more or less misleading models. Dissections are made to illustrate the book. The printed description is learned by rote, and the dissection practised too often simply as a manual exercise. The anatomy of the medical college is largely a memory drill—such as belongs pedagogically in the secondary schools. These seventeenth-century notions have been passed from anatomy to physiology. That which began as a makeshift has become a dogma.

Practical work in physiology has also been kept back by the erroneous ideas that the cost of apparatus and other materials is prohibitory, that medical students cannot master the details of exact experimentation, that delicate apparatus cannot be trusted in their hands, and that instruction to the extent required cannot be given to large classes because the course will become too complicated to be carried out.

Perhaps the chief obstacle which has kept physiology in an ancient and now almost abandoned path, is the public belief that because anatomy and physiology were once taught chiefly from books, they should still be so taught; that the functions of living organs can be learned from books with the occasional exhibition of dead organs; that the natural sciences should continue to be studied in secondary schools without laboratory work; in brief, that nature can be studied apart from nature. The public has a just contempt for men who profess to have learned disease without practical observation of the sick—experience is conceded to be necessary here—but the public is ready to applaud, and even to compel by law the study of the same organs in their normal state by reading or hearing a description at second hand of what some third person saw. The real drags upon progress are the failure of the secondary schools to teach science by scientific methods, and the fatal conservatism that binds teachers of medicine to a past that we should do well to forget. These venerable delusions no longer impede experts in pedagogy, but unfortunately medical teachers for the most part are more zealous than learned in pedagogy. They fail to see that medical training should be "for power," and only secondarily for information.

If it be replied to these strictures that a system which produces so many able physicians cannot be much in need of improvement, I answer that the men of talent veil the defects of the mass. They owe much to themselves; genius will thrive on the intellectual diet that stunts the merely industrious man. The average student does not build upon a sound foundation. He knows little anatomy, less physiology, and still less chemistry, and even his training in practical medicine has to be supplemented where possible by postgraduate work in a hospital. On the whole, it may be said that his industry has been largely misdirected.

The picture I have drawn of the instruction in physiology in the average medical school will be accepted by teachers of that science. The sense that the usual methods of instruction neither develop nor much inform the mind is general. Careful inquiry should therefore be made to determine how far the defects can be remedied with the means at our disposal. The problem is: How far can the correct theory be realised in practice? To what extent can all students of physiology be taught in the manner in which men are trained to be professional physiologists? Evidently physiologists are likely to study their own subject in the most profitable and labour-saving way.

The expansion of physiology has broken it into specialities. Even professional physiologists can no longer have personal acquaintance with the whole subject, or even a relatively large part of it. To a considerable degree the physiologist himself must acquire his information from reading the work of others. It would therefore be idle to expect the student to get a personal experimental knowledge of the whole subject. His limited time must be used chiefly for training, and not chiefly for the acquisition of facts, as at present, and this training must follow the lines laid down by physiologists for their own development.

Deal so far as possible with the phenomena themselves, and not with the descriptions of them. Where the fundamental experiments cannot all be performed, fill the gap with the original protocols from the classical sources. Associate facts which the student can observe for himself with those which he cannot observe. Use as the basis of professional instruction, where practicable, the facts and methods to be used by the student in earning his living. Teach the elements by practical work. Let the student state his observations and results in a laboratory note-book, which, together with the graphic records of his experiments, shall form one of the requirements for the degree. Control his progress and remove his difficulties by a daily written examination and a daily conference, in which the instructor shall discuss the observations made by the student and supplement them from his own reading. Stimulate the student by personal intercourse in the laboratory, by glimpses of the researches in progress, and by constant reference to the original sources. Diminish the distance between professor and pupil; both are students, and both should be fed on the same intellectual diet. There is but one way to get and keep an education. Demand of every student a written discussion of some very limited thesis, giving the results of the original investigators, together with any observations the student has made for himself. Give the more capable students opportunity for original experimental work. Towards the end of the instruction, when the student is ripe for such work, offer a liberal number of courses of didactic lectures with demonstrations. Let each course consist of from one to four lectures not more than forty-five minutes in length, presenting all that is known of the chosen subject. These lectures should show the student the historical development of scientific problems, the nature of scientific evidence, and the canons of criticism that help to sift the wheat from the chaff of controversy. From the beginning to the end of the instruction hold fast to concentration, sequence and election. Such are the lines along which sound theory would direct the teaching of physiology in medical schools.

Concentration, sequence and election are the safeguards of economical labour.

Whether the student's time is to be given wholly or only in part to the subject taught is the first problem to be solved in planning the actual instruction. Men in training for professional physiology commonly concentrate their energies for a sufficient period on this one subject; and this is regarded as the most economical way of mastering any science, for the ground gained by one day's work is still fresh in the mind when the next day's work begins, and continuity of thought is not disturbed. The plea that the instruction in one subject should be broken by the study of other subjects in order that the instruction in each may have "time to sink in" need not be entertained; experience shows that much of it sinks in so far that it cannot be recovered without the loss of valuable energy. A more serious objection is that the method of continuous application is highly fruitful in men of exceptional powers, who are keen in spite of protracted effort, but is wasteful for the average brain, which is fatigued and unreceptive after some hours of unremitting labour. The truth of this must be allowed; but the objection does not apply to wide-ranging sciences such as anatomy and physiology, which are not narrow, hedged-in areas, but which consist rather of broad and diversified domains composed of many contiguous fields, the varied nature of which is a perpetual refreshment.

A correct sequence of study is also highly important. Very often in medical schools the lectures in physiology are given before the student has any acquaintance with the anatomy of the structures considered, and still more are heard before the student has any true anatomical knowledge—that based on actual contact with tissues and not upon a glimpse of a distant prosection or a hasty glance at a diagram. Similar instances are not uncommon in later parts of the curriculum. The natural sequence demands that the study of structure should precede the study of function, and the study of the normal precede that of the abnormal. Thus the natural order of medical study is descriptive anatomy, physiology, pathology and medicine. There is a considerable advantage in treating organs individually, studying their structure, physiology, pathology, diseases and treatment in continuity, but practical difficulties in arranging such a course make this inadvisable.

Election is correct in theory and unavoidable in practice. Generations have passed since it was possible to teach every clever student all things. Yet in many schools the effort is still made. The herd of students is driven hastily past the monuments of genius and learning in the hope that they who run may read. Students are exhorted to be great, while littleness

is thrust upon them. The obstetrician and the ophthalmologist still receive the same instruction. It is obvious, however, that this indiscriminate gorge will be soon an unpleasant memory. The wonderful growth of medicine is breaking bonds already centuries old. All minds in one mould is ceasing to be the ruling axiom in medical teaching, not because it is a terrible delusion which by retarding discovery has cost the lives of countless thousands, but because it is no longer practical. Success demands some acquaintance with all subjects and an intimate knowledge of one. Day by day the walls rise higher between one speciality and another. The parting of the ways begins at the threshold. In anatomy, physiology and pathology the student should spend his time on those portions which are directly associated with his future work as practitioner or investigator.

This early election will be strenuously resisted by partisans of the tradition. They will contend that the present instruction embracing the entire field is known to give a very inadequate acquaintance with the subjects taught; therefore, instruction covering only a part of the ground will give still less. The argument is beside the mark. The present method of instruction would be inadequate in any event. The medical degree is granted for superficial information in twenty-five or thirty subjects. The sign of the scholar and man of science, namely, thorough knowledge of some one field, is wanting. Yet this training of the man of science is more and more necessary for success. Moreover, a thorough training in at least one subject increases the power of acquiring the fundamental data of related subjects while it protects the mind against superficiality. A further necessity for election is seen in the fact that the great medical schools are university departments. They are attended by an increasing number of men who will never practise medicine but will become investigators in some branch of biological science.

Following the idea of concentration, sequence and election, I have proposed that the student's undivided attention be given to one principal subject at a time. The principal subjects in medicine are anatomy, physiology, pathology and clinical medicine including surgery. The four years' course in medicine is divided into eight terms or semesters, which usually comprise sixteen weeks of instruction. The first of the eight terms may be given to the primary course in anatomy, including histology; the second to the primary course in physiology, including physiological chemistry; the third to the primary course in pathology, including bacteriology; the fourth to pharmacology, clinical chemistry and physical diagnosis; and the four remaining terms to clinical medicine and surgery. The primary courses just mentioned provide the instruction in anatomy, physiology and pathology which every student is advised to take. Advanced instruction in these subjects may be offered in subsequent elective courses.

To meet the needs of the several classes of students found in universities the department of physiology must provide: (1) The primary course already mentioned, suitable for every student of biological science, including medicine; (2) An advanced course, intermediate between the primary course and research; this advanced course will be taken by candidates for the degree of Doctor of Philosophy who have selected physiology either as their principal subject or as one of the two or three subordinate subjects required of such candidates; (3) Opportunities for physiological research.

The primary course in physiology is held from 9 a.m. to 1 p.m. daily during the second term of four months in the first year of the medical curriculum. The afternoons of these four months are devoted to physiological chemistry. The primary instruction in physiology is divided into three parts. Part i., of five weeks' duration, provides thorough experimental work in some limited field. In this, the student should acquire the point of view, the general physiological method, training in technique, and a complete knowledge of one or more tissues to serve as an introduction to the physiology of the remaining tissues. There can be little doubt that the physiology of muscle and nerve should be chosen for this purpose. It is the most fully developed chapter in physiology, and is well adapted to train the mind in habits of exact experimentation and close reasoning. Moreover, the physiology of muscle and nerve is in large measure the physiology of all living tissues, so that a man learned in this one field is in effect already acquainted with the general principles of physiology. Part ii., of about seven weeks' duration, comprises carefully arranged fundamental experiments, giving in turn the elements of each field in physiology except that of nerve and muscle, which has just been studied. In part iii., covering the remainder of the term of sixteen weeks, the instruction is divided into special courses on the physiology of the eye, ear, larynx, digestion, the spinal cord, the innervation of the heart, &c. Each course is long enough to include all the practicable experiments that should find a place in a systematic, thorough study of the subject. The number of such experiments, and hence the length of the special courses, is naturally different in the various instances; thus the experimental physiology of the eye occupies more time than the physiology of the larynx. The student may elect the subjects that most interest him, but must choose a sufficient number to occupy him during the entire four weeks of instruction. In planning these courses the aid of distinguished specialists is sought.

Each student is required to present one written discussion of some small and sufficently isolated thesis, giving the work of the original investigators. The way of dealing with the sources at first hand is thus learned. Many of these essays are read and discussed before the class. The discussions begin with the sixth week of the course and are held daily during nine weeks. None is held during the last two weeks. The literature of each subject is divided into two portions and each is assigned to one man. The fifty-four subjects, therefore, are presented in one hundred and eight essays. The men chosen for this purpose are the best in the class; their choice is determined at first by the results of their examinations in anatomy, and, so soon as practicable, by the results of their work in physiology. In addition to the two men who read theses, one or more of the investigations on each subject are studied by four men, who are thus specially qualified for the discussion. The four are selected in turn from the whole class. To illustrate, let us take as an example "The Transmission of the Cardiac Excitation Wave." One student defends the theory that the cardiac excitation wave is transmitted through muscular tissue; a second defends transmission through nerve tissue. Each presents a carefully written account of the evidence pro and con. The four men, each of whom has read at least one of the investigations on this subject, lead the discussion, which is held by the entire class and the departmental staff. The subjects chosen for discussion are, as a rule, such as cannot be fully studied in the laboratory. Thus the discussions complement the remaining instruction. The subjects to be discussed are bulletined before the appointed day so that the class may come to the discussion somewhat prepared.

In the last two weeks of the course, students who have performed their experimental work especially well may elect instruction in physiological research. The subject chosen must necessarily be very narrow, and, where possible, should be one the literature of which has been already examined in the preparation of the student's thesis. Experience has shown that after fourteen weeks of strenuous labour in experimental physiology, the student of average ability learns to work rapidly and carefully, so that much can be accomplished in two weeks of experimentation in one small subject. Even a very brief experience of investigation is of the greatest value and interest. Examples of subjects suitable for training in investigation are: "The Compensatory Pause;" "The Tetanus Curve;" "The Action of Calcium and Sodium Ions on Rhythmic Contractility."

Beginning with the second week of the course, a daily written examination, twenty minutes in length, is held. One or, at most, two questions are asked. They concern the student's own experiments. The purpose of the examination is to cultivate precision in statement. The emphasis which the question gives imparts a correct perspective. Further, the examination reveals men whose indolence or incapacity marks them for special care. The following questions are some of those asked in such examinations: "Give experimental evidence to show where stimulation begins on the closure of the galvanic current. Explain the difference between the stimulating electrodes and the physiological anode and kathode in the stimulation of human nerves. Give the experimental basis for an explanation of the auriculo-ventricular interval."

The didactic instruction consists of a ten-minute talk in the laboratory, commenting on the examination of the previous day and explaining any special difficulties in the experiments, and of a daily lecture. In every instance this lecture is intended to discuss experiments. Wherever possible the experiments are to be performed by the students themselves before coming to the lecture. Experiments which the students cannot do for themselves

are studied by them from the original protocols, furnished with a suitable explanatory text. Thus the fundamental elementary information is gained from the original sources before the lectures. The students are questioned concerning these fundamental experiments. The questions are arranged in the sequence required for a systematic presentation of the subject. Wherever necessary, the lecturer adds from his own stores to the information already possessed by the student. The class is encouraged to question the lecturer concerning matters not quite clear. At the close of the exercise the lecturer sums up briefly. The end in view is the development of the mind rather than the imparting of information. For example, the fact that the pressure of the saliva in the ducts of the submaxillary gland during secretion is higher than that of the blood in the carotid artery is not presented as a fact to be memorised, but is discussed with reference to its bearing on secretion by filtration; the student has learned the fact itself from the original source before coming to the lecture. Some of the lectures on special subjects, such as the eye, are given by distinguished specialists in practical medicine. Each instructor gives as an elective one or more lectures describing, with demonstrations, his own investigations; the investigator discussing his own experiments is a powerful intellectual stimulus; too little account has been taken of this educational force.

The student should be provided with what may be called a laboratory text-book. This text-book consists of a series of experiments and observations, taken from the original sources, and arranged in the sequence suited to develop the subject. Very often the historical sequence serves this purpose best. The description of the experiment follows the original so far as practicable. The experiments are provided with a suitable commentary text. The student is made to feel at every step that physiology is an experimental science, that the only material proper for discussion consists of observations and experiments free from error, and that safety demands constant reference to the original source. The laboratory text-book is supplemented by the student's laboratory note-book, in which the student preserves the graphic records of his experiments and the notes of his observations.

Little need be said concerning the instruction intermediate between the primary course and research. In the intermediate course the experiments chosen for the individual student vary with his goal, and are arranged in the order that seems best adapted to train the mind for research in the direction desired.

The methods of primary and advanced instruction here presented are obviously the methods of the investigator. They can be carried out effectively only by those whose chief purpose is the advancement of human welfare by discovery. In many schools, instructors are still selected mainly because they can talk agreeably of the work of others; in some, the instructor must have made one experimental study in the subject which he teaches; in a very few of the large schools, the higher positions are occasionally bestowed on men to whom research is more than a memory, but these positions almost invariably are burdened with a mass of petty administrative detail. The university devotes these men to researches which the university prevents them from making. Thereby its best minds are set to its lowest work. A change is necessary here. No man who has not made at least one experimental investigation should be appointed assistant in a department of physiology, no man who has not shown marked capacity for original work should be made instructor, and the professor's chair should be filled only by those in whom the ardour of discovery is not likely to be cooled by the advancing years. At least half the day should be set aside for research, and the hours thus reserved for the highest studies should be guarded against every encroachment. The best elementary instruction can be given only in the atmosphere of research. Discovery fires the imagination of youth, consoles the aged, and lifts the mind from mediocrity to greatness.

W. T. PORTER.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—The following is the text of the speech (composed by Mr. A. C. Clark of Queen's College) delivered by Prof. Love in presenting Principal Lodge for the degree of D.Sc. *honoris causa* on February 12:—

Adest Oliverus Josephus Lodge, Naturæ rerum indagator acerrimus. Qui, ut vitam eius brevissime percurram, iam quinquaginta abhinc annos natus in Collegio Universitatis Londinensis primo institutus, in Universitate Londinensi gradum Doctoris Scientiæ adeptus est: mox in Collegio Universitatis de Liverpool Professor Physicæ creatus summa laude viginti annos floruit: anno denique proximo Universitatis novæ de Birmingham primus Præses factus est. Magna iamdudum fama inclaruit hic vir, quod in rebus physicis experimentorum longum ordinem peritissime commentus est et felicissime confecit: quo in genere sæpe numero ei contigit ut re acu tacta difficillimam aliquam quæstionem, in qua hæserant doctissimi Physicæ auctores, felicissime explicaret. Primo quidem quæ et qualis sit vis illa Naturæ moderatrix, quam ἐνέργειαν vocant, quibus mutationibus utatur, quærebat, neque laborum laude debita diu caruit a Regali Societate iam tredecim abhinc annos Sodalis electus. Iam tum vestigia Fitzgeraldiana secutus radiorum electricorum naturæ studere inceperat. Docuerat enim Maxwell, huius rei peritissimus, vim electricam oscillationibus quibusdam per inane spatium transferri posse, quo duce usi apud Germanos Hertzius, apud nostros Lodge, harum oscillationum signa et indicia certa deprehendere conabantur. Hertzium quidem ad metam primum pervenisse non nego, ad quam tamen Lodge eandem viam ingressus certo cursu ferebatur: illud vero affirmaverim veritate ab Hertzio patefacta hunc meliorem viam quærentibus monstravisse et novæ doctrinæ prædicatorem insignissimum exstitisse. Neque civium utilitatibus non inserviebant eius labores, cum in nuntiis arte telegraphica sine filo metallico mittendis, tum in fulminibus avertendis et in postes aeneos, tectorum nostrorum tutamina, sine fraude derivandis. His denique diebus magnam rem felicissime aggressus est cum quæreret de terræ cursu per medium illud ætherium, quo lux et vis omnis electrica et magnetica pervehitur, et doceret hoc medium, quod vocant, penitus stagnare et materiæ crassioris motibus omnino carere. Multum denique profecit in natura radiorum illorum explicanda quos Lenardus, Röntgen, Zeeman, viri acutissimi, primi detexerunt. Insignem eius operam in his variis generibus agnovit Universitas Sancti Andreaa, quæ gradu Legum Doctoris, et Regalis Societas quæ numismate aureo Rumfordiano eum iure ornavit.

Neque id silendum arbitror quod huic viro intima Naturæ penetralia reserare nequaquam satis erat, sed et in tironibus instituendis et in rebus gubernandis pari industria et felicitate eminuit: quo in genere haud parvam partem laudis suæ debet Universitas de Liverpool, de qua optime meritus est. Huius viri ingenio multiplici latior profecto campus iam datur, cum Universitatis novæ de Birmingham Præfectus sit.

The Junior Scientific Club held their 221st meeting on Friday, February 15. Mr. W. B. Croft, M.D., of Pembroke, read a paper on "The management of light waves," which was followed by a paper by Mr. A. C. Inman, of Wadham, entitled "René Descartés, and his physiology."

Mr. R. E. Baynes, Lee's Reader in Physics, has been appointed a delegate of the University Museum, in place of Sir John Conroy, F.R.S., deceased.

The Provost of Oriel (D. B. Munro) and the President of Trinity (H. F. Pelham) have been appointed representatives at the ninth Jubilee of the University of Glasgow.

CAMBRIDGE.—Mr. W. D. Niven, F R.S., has been appointed an elector to the Cavendish professorship of experimental physics.

THE *American Naturalist* for January gives a list of gifts and bequests made to various educational institutes in the United States for eleven months of the year 1900, ending November 30; they amount to over sixteen million dollars. The largest amount is a gift, not to exceed three million dollars, from Mr. Andrew Carnegie, for the enlargement of the Carnegie Institute, Pittsburg, Pennsylvania. The number of gifts or bequests recorded is about eighty.

THE report of the Technical Education Committee of the Derbyshire County Council shows that continued progress is being made in the provision of adequate laboratory and workshop accommodation in important centres of the county. In the department of agriculture, the headquarters of the agricultural teaching have been transferred from Nottingham to the farm centre at Kingston, where additional buildings have been constructed to enable practical science work to be carried on.

THE Senate of the Royal University of Ireland has passed the following resolution:—"That in the opinion of the Senate the

relations of the University with its own colleges and students are unsatisfactory, and it is most desirable that a Royal Commission should be issued to inquire into the working of this University as an examining and teaching body in relation to the educational needs of the country at large, and to report as to the means by which University education in Ireland might receive a greater extension and be more efficiently conducted than it is at present."

AN influential committee, headed by the Duke of Devonshire, the Duke of Argyll, the Earl of Derby and Earl Spencer, have issued an appeal with the object of raising 150,000*l.* in celebration of the jubilee of Owens College, Manchester. Fifty thousand pounds are needed to discharge debts that have been contracted and 100,000*l.* for additional endowment. Among the objects the promoters have in view are the extinction of the debt of 22,000*l.* on the buildings of the medical school; special endowments for existing chairs, including chemistry, education, anatomy and philosophy; the establishment of an institution for bacteriological investigation and for the study of hygiene, and of research Fellowships; and the creation of a pension fund for members of the teaching staff.

SCIENTIFIC SERIALS.

American Journal of Mathematics, vol. xxiii. No. 1, January.—The new volume opens with a memoir by S. Kantor, entitled "Die Typen der linearen Complexe rationaler curven im R_r."—E. J. Wilczynski writes on transformation of systems of linear differential equations. It has been shown by Staeckel (*Crelle*, band 111) that the most general transformation, which converts a general homogeneous linear differential equation of order $m > 1$ into another of the same form and order, is

$$\mathrm{T}: x=f(\xi), y=\phi(\xi)\eta,$$

where $f(\xi)$ and $\phi(\xi)$ are arbitrary functions of ξ. If $m=1$ the most general transformation is

$$x=f(\xi), y=\phi(\xi)\eta^{\lambda} \text{ (λ a constant).}$$

The present paper considers a *system* of linear differential equations, and finds the most general transformation which converts such a system into a system of the same order. The transformation thus formed contains T as a special case. Staeckel's method is adopted in essence. The author is working at a theory of invariants of such systems, based on this general transformation.—Distribution of the ternary linear homogeneous substitutions in a Galois field into complete sets of conjugate substitutions, by L. E. Dickson, and the following paper, "Distribution of the quaternary linear homogeneous substitutions in a Galois field into complete sets of conjugate substitutions," by T. M. Putnam, are in continuation of a memoir by the former writer in vol. xxii. (pp. 121–137).—On the determination and solution of the metacyclic quintic equations with rational coefficients, by J. C. Glashan, is a tardy fulfilment of a promise made in vol. vi. p. 114.—E. O. Lovett contributes a construction of the geometry of Euclidean n-dimensional space by the theory of continuous groups.—A table of class numbers for cubic fields, by Legh W. Reid, is calculated with a view to furnishing for the general algebraic number fields an amount of number material sufficiently great to be of use in the further study of these fields, and in particular in that of the cubic fields. It gives for each of 161 cubic number fields the class number, h, the discriminant Δ, a basis, and the factorisation of certain rational primes into their prime ideal factors. The method is founded upon a theorem of Minkowski's. In every ideal class there is an ideal, j, whose norm, $n(\mathrm{j})$, satisfies the condition

$$n(\mathrm{j}) < \left(\frac{4}{\pi}\right)^r \frac{m!}{m^m} \left| \sqrt{\Delta} \right|,$$

where m is the degree and Δ the discriminant of the field, and r the number of pairs of imaginary fields found among the m conjugate fields, $k^{(1)}, k^{(2)}, \ldots k^{(m)}$. The writer refers to Hilbert, "Bericht über die Theorie der Algebraischen Zahlkörper"; Minkowski, "Geometrie der Zahlen," and Woronoj, "The algebraic integers, which are functions of a root of an equation of the third degree" (translation of Russian title). The tables take up ten pages.—On certain properties of the plane cubic curve in relation to the circular points at infinity, by R. A. Roberts, contains an investigation of some methods of generating a plane cubic curve.—With this opening number is presented an excellent portrait of Dr. George Salmon, and a supplement gives a still more excellent one of Prof. Mittag Leffler.—Prof. Frank Morley is the editor in chief.

Bulletin of the American Mathematical Society, January.—Prof. Lovett gives an account of the proceedings at the International Congress of Philosophy, which was held at Paris on August 1–5, 1900, and furnishes *résumés* of the papers read and the discussions occasioned by them, so far as they bore, more or less directly, upon mathematical questions. The sketch is founded upon the account printed in the September (1900) number of the *Revue de Métaphysique et de Morale*. It occupies pp. 157–183.—A demonstration of the impossibility of a triply asymptotic system of surfaces, by Dr. Eisenhart, was read before the Society on December 28, 1900. It is a notelet founded upon Bianchi's Lezioni.—Prof. E. W. Brown writes short notices of Berry's "Short History of Astronomy" and of H. Suter's "Die Mathematiker und Astronomen der Araber und ihre Werke." This latter, though only a catalogue of over five hundred names of mathematicians and astronomers, and so at first sight not giving promise of much interest, is really, as Prof. Brown shows, a work of considerable interest. He illustrates this statement by a few extracts.—There are a fair amount of notes and new publications.

SOCIETIES AND ACADEMIES.

LONDON.

Physical Society, February 22.—Prof. S. P. Thompson, president, in the chair.—A paper on how air subjected to X-rays loses its discharging property, and how it discharges electricity, by Prof. Emilio Villari (Hon. Fellow), was read by the chairman. Air made active by X-rays in passing through a long tube coiled in many turns loses much more of its discharging power than it does in passing through the same tube if straight. During this process the tube charges itself to a certain potential. If active air is allowed to stream on masses of wire gauze or wound up ribbons, enclosed in tubes, the metals, independent of their nature, take a positive or negative charge according to whether the active air rubs against them with force or lightly. Experiments have been performed to prove this. For instance, tubes of copper or lead, if short and straight, take negative charges, but if long and coiled they take positive charges. These phenomena cannot be attributed to chemical actions, but seem to be produced by a special rubbing of the active air upon metallic surfaces, as the result of which they assume one of the charges, and the other charge ought to manifest itself in the air. This is not the case, the charge of the air being often of the same kind as that of the metals. It has previously been shown by the author that active air by streaming against an electrified body is reduced either to ordinary air or to air charged with the electricity which disappears. Hence it may be supposed that the active air in rubbing upon the metallic surfaces develops the two electricities, one of which manifests itself upon these surfaces, and the other goes to reduce the active air to ordinary air, and therefore does not become manifest. The electroscope used in the experiments consisted of a fixed brass plate and a gold leaf whose position was determined by means of a telescope with an eye-piece scale.—The chairman said he had observed the fact that metals were charged sometimes positively and sometimes negatively by active air. Mr. Watson asked if any experiments had been performed on the viscosity of gases rendered active by X-rays.—A paper on the propagation of cusped waves and their relation to the primary and secondary focal lines, by Prof. R. W. Wood, was read by Mr. Watson. This paper is a discussion of the reflexion of a plane wave by a hemispherical mirror, the reflected wave being likened to a volcanic cone. The cusp of the wave, or the rim of the crater, traces the caustic and is continuously passing through a focus. This accounts for the increased illumination along the caustic. The wave fronts were drawn by constructing the orthogonal surface, which in section is an epicycloid. The evolute of this curve is the caustic, and the reflected wave fronts form a family of parallel curves which are the involutes of the caustic. The wave front between two focal lines is expanding along one meridian and contracting along a meridian at right angles to it; in other words, the wave is convex along one meridian and concave along the other. The outer slope of the volcanic cone representing the reflected wave corresponds to the portion of the wave front between the focal

lines. A useful piece of apparatus can be made by silvering the outside of a hemispherical glass vessel. The concave mirror thus formed should be mounted on a stand, and a small electric lamp arranged so that it can move along the axis of the mirror. A spherical wave starting at the focus of a hemispherical mirror is reflected as a saucer-shaped wave, the curved sides of the saucer coming to a focus in a ring surrounding the nearly flat circular bottom. If the lamp is placed at the focus the luminous ring and the uniformly illuminated area within it can be shown on a ground glass screen. If the lamp be moved to a point midway between the focus and the mirror, a ring of intense brilliance, with very little light within it, is formed.—A paper on cyanine prisms, by Prof. R. W. Wood, was read by Mr. Watson. Prof. Wood has already described a method of making prisms of solid cyanine by pressing the fused dye between plates of glass. Until recently, angles of about half a degree were the largest that could be used with advantage on account of the small quantity of green light transmitted. A new supply of the dye has been found to transmit a large quantity of green light with an angle of over one degree. By viewing the filament of an incandescent electric lamp through one of these prisms the anomalous spectrum is seen, the colours being arranged in the order green, blue, violet, red, orange. Prof. Wood has crossed one of these prisms with a photographic copy of a diffraction grating having 2000 lines to the inch. On viewing a naked arc lamp the diffraction spectra are deviated by the prism, the red ends being turned up and the blue-green ends turned down.—The chairman said he had been trying to obtain some cyanine, but had not succeeded. Rosaniline has an anomalous dispersion, but cannot be fused. The acetate of rosaniline might, however, be used. The Society then adjourned until March 8.

Chemical Society, February 7.—Prof. Thorpe, president, in the chair.—The action of hydrogen bromide on carbohydrates, by H. J. H. Fenton and M. Gostling. The authors, having previously shown that bromomethylfurfuraldehyde results from the action of hydrogen bromide on lævulose, sorbose, inulin or cane sugar, now show that all forms of cellulose give large yields of the same bromomethylfurfuraldehyde under similar conditions; since the formation of this substance is characteristic of ketohexoses or of substances which give rise to them by hydrolysis, it seems conclusively proved that cellulose contains a nucleus similar to that of lævulose.—The ketonic constitution of cellulose, by C. F. Cross and E. J. Bevan. The authors contribute a statement of the evidence, other than that contained in the previous paper, in favour of the supposition that lævulose or some other ketose is the raw material used in the plant for the elaboration of cellulose.—Note on a method for comparing the affinity values of acids, by H. J. H. Fenton and H. O. Jones. The authors have shown that oxalacetic phenylhydrazone is decomposed on heating with water, giving carbon dioxide and pyruvic hydrazone, whilst on heating with acids, pyrazolone carboxylic acid and water are produced in accordance with the following equations:—

$$\begin{array}{c} CH_2.CO_2H \\ | \\ C:N_2HPh \\ | \\ CO_2H \end{array} = \begin{array}{c} CH_3 \\ | \\ C:N_2HPh + CO_2. \\ | \\ CO_2H. \end{array}$$

$$\begin{array}{c} CH_2.CO.OH \\ | \\ C:N.NHPh \\ | \\ CO_2H \end{array} = \begin{array}{c} CH_2.CO \\ | \quad\ | \\ C:N.NPh + H_2O. \\ | \\ CO_2H \end{array}$$

It is shown that, on heating with acids, the volumes of carbon dioxide evolved are in the inverse order of the affinity values of the acids used, other conditions remaining the same.—Organic derivatives of phosphoryl chloride and the space configuration of the valencies of phosphorus, by R. M. Caven. The author has prepared substituted phosphoryl chlorides of the form $OP\begin{cases} R_1 \\ R_2 \\ R_3 \end{cases}$, in which the groups R_1, R_2 and R_3 are ethoxyl and the anilido- and paratoluido-residues respectively; the same substance is obtained irrespective of the order in which the substituting groups are put into the molecule, and the author therefore concludes that these three groups are similarly situated with respect to the rest of the molecule.—α-Hydroxycamphorcarboxylic acid, by A. Lapworth and E. M. Chapman. A method for the preparation of camphorquinone in quantity is given, and it is shown that this substance reacts with hydrogen cyanide to form a mixture of stereoisomeric α-hydroxycyanocamphors, $C_8H_{14}\begin{cases} C(OH).CN \\ | \\ CO \end{cases}$; this substance behaves as an α-hydroxynitrile, and may be hydrolysed to α-hydroxycamphorcarboxylic acid, $C_8H_{14}\begin{cases} C(OH).CO_2H \\ | \\ CO \end{cases}$.—The bacterial decomposition of formic acid, by W. C. C. Pakes and W. H. Jollyman. The authors show that certain bacteria decompose formic acid as sodium formate into equal volumes of carbon dioxide and hydrogen.—Preparation of substituted amides from the corresponding sodamide, by A. W. Titherley.—Note on two molecular compounds of acetamide, by A. W. Titherley.—Diacetamide: a new method of preparation, by A. W. Titherley.—Diacetamide may be directly prepared by the action of acetyl chloride on acetamide.—Organic derivatives of silicon, by F. S. Kipping and L. L. Lloyd. Silicon tetrachloride, when treated with one molecular proportion of an alchohol, exchanges one chlorine atom for an alkyloxy-group yielding a substance of the composition $SiCl_3.OR$. The latter, by similar treatment with two other alcohols, can be converted ultimately into a substance of the constitution $SiCl(OR_1)(OR_2).OR_3$.—Isomeric hydrindamine camphor-π-sulphonates. Racemisation of α-bromocamphor, by F. S. Kipping. From the examination of the *dl*-hydrindamine *d*-camphor-π-sulphonate, it is concluded that slight racemisation occurs during the sulphonation of *dα*-bromocamphor.—Tetramethylene carbinol, by W. H. Perkin, jun. Tetramethylenecarboxylic chloride is reduced by sodium and moist ether to tetramethylene carbinol, a colourless oil boiling at 143–144°.

Zoological Society, February 5.—Mr. Howard Saunders, vice-president, in the chair.—Mr. Sclater called attention to the fine specimen of Prjevalsky's Horse (*Equus prjevalskii*) now mounted and exhibited in the gallery of the Muséum d'Histoire Naturelle of Paris, and made some remarks on its structure and peculiarities.—Mr. Oldfield Thomas gave an account of the mammals which Mr. R. I. Pocock and he had collected during a trip to the Balearic Islands in the spring of 1899. Twenty-four species were enumerated and remarked upon, amongst which was a new form of hedgehog, described as *Erinaceus algirus vagans*.—Dr. W. G. Ridewood read a paper on the horny excrescence on the snout of the southern right whale (*Balaena australis*), known to whalers as the "bonnet," in which he showed that the minute structure is the same in essential features as that of the *stratum corneum* of the normal skin of the whale. The cuticular fibres were set at right angles to the surface, and were not sharply differentiated or readily separable. Comparisons were drawn by the author between the structure of this horny excrescence and that of the nasal horn of the rhinoceros, the hoof of the horse, the horn of the ox and the baleen of the whale.—Mr. G. A. Boulenger, F.R.S., enumerated the species of batrachians and reptiles represented in a collection made by Dr. Donaldson Smith in Somaliland in 1899. Of the reptiles two were new to science and were described under the names *Hemidactylus laevis* and *H. barodanus*.—Mr. Sclater made some additional remarks on the two pieces of zebra-skin, exhibited at a previous meeting, which had been sent to him by Sir H. H. Johnston, K.C.B., from the Semleki Forest on the borders of the Uganda Protectorate, and expressed his opinion that they belonged to a hitherto unknown species, for which he proposed the provisional name of *Equus johnstoni*.—Mr. J. L. Bonhote read a paper on a second collection of Siamese mammals made by Mr. Th. H. Lyle, consul at Nau, Siam. The collection, although small, was of considerable interest, the twenty specimens composing it being referable to eleven species, one of which, *Sciurus macclellandi kongensis*, was described as new. Mr. Bonhote also communicated a paper containing an enumeration of the 139 species of birds of which specimens had been collected during the "Skeat Expedition" to the Malay Peninsula in 1899–1900.—Mr. F. E. Beddard, F.R.S., described a new species of freshwater annelid, under the name of *Bothrioneuron iris*, from specimens obtained in the Malay Peninsula during the "Skeat Expedition" in 1899–1900.

Entomological Society, February 6.—The Rev. Canon Fowler, president, in the chair.—The president exhibited a specimen of *Colias edusa* var. *helice*, with the margins of the

wings entirely dark, as in the male; also a variety of *Cartero-cephalus palaemon*, with the hind wings dark save for one conspicuous orange spot.—Dr. T. A. Chapman exhibited a large series of Endrosæ, collected during the last few years by himself, Mr. A. H. Jones, and especially by Mr. Tutt, showing the relative approximation of the several species. Except *irrorella* from England, Finmark, and the Tyrol, and a few *aurita* from the Tyrol, all were from the Western Alps of Switzerland, Italy and France. Examples from each locality, he said, when sufficiently numerous usually have a special facies. Some, as all those from Arolla, radiate; those from Bourg St. Maurice are without radiate forms, and so on. Some are more yellow; others deeper orange; some more mixed. Elevation tends to produce radiation, but no other general conclusion as to the effect of height, latitude or longitude seems fully justified by the specimens.—Mr. G. C. Barrett exhibited for Mr. G. O. Day, of Knutsford, a black variety of *Aplecta nebulosa*, Tr., with white cilia, and an asymmetrical ♀ var. of *Fidonia atomaria*, Linn.—Mr. M. Jacoby exhibited an unknown specimen of the family Halticidæ.—Mrs. Nicholl exhibited a collection of Rhopalocera from the Lebanon district of Syria, and Mr. H. J. Elwes, on her behalf, read a paper explaining and illustrating the several species included. Among other species Mr. Elwes drew especial attention to *Thecla myrtale*, which, since it was described by Klug in 1832, has remained one of the least known members of the palæarctic fauna. No specimens, it appears, had been taken in the interval until Mrs. Nicholl found it on the high mountains not uncommonly in May and June.—The following papers were communicated:—A revision of the genus Astathes, Newm., and allied genera of Longicorn Coleoptera, by C. J. Gahan, M.A., and a preliminary catalogue of the Lepidoptera-Heterocera of Trinidad, by W. J. Kaye.

Linnean Society, February 7.—Prof. S. H. Vines, F.R.S., president, in the chair.—Mr. H. W. Monckton exhibited some lantern-slides showing a large ammonite in the Kimmeridge clay at Swanage, and several views taken at the Pentland oyster-bed at Tilly Whim, and the Purbeck oyster-bed in Durleston Bay.—The president, whilst demonstrating the property possessed by certain vegetable liquids, such as coconut milk and the juice of the pineapple and the potato, to cause the oxidation of guaiacum tincture in the presence of hydrogen peroxide, a blue colour being produced, drew attention to the recent researches of Raciborski on the subject. Raciborski has made the interesting discovery that certain tissues of the plant-body, more particularly the sieve-tubes and the laticiferous tissue, contain some substance, to which he gives the name *leptomin*, which likewise causes guaiacum to turn blue in the presence of hydrogen peroxide, and has gone on to infer that this leptomin may be regarded as discharging in the plant a function analogous to that of hæmoglobin in the animal body. The president urged, against this assumption, that although both leptomin and hæmoglobin give the guaiacum reaction, yet this fact does not prove that leptomin can combine with oxygen, and can act as an oxygen-carrier in the organism, in the manner which is so characteristic of hæmoglobin; and that, therefore, the suggested analogy between the two substances is at least premature.—Mr. H. M. Bernard read a paper, of which an abstract had been previously circulated, on the necessity for a provisional nomenclature for those forms of life which cannot be at once arranged in a natural system. A discussion followed in which Prof. Ray Lankester, Sir W. T. Thiselton-Dyer, Mr. Bateson, Mr. Elwes, and Prof. Jeffery Bell took part. It was proposed by Prof. Lankester, and seconded by Mr. H. J. Elwes, that the discussion be adjourned to another meeting, and that resolutions be framed for submission to that meeting when called.

Anthropological Institute, February 12.—Prof. Haddon, F.R.S., in the chair.—Mr. A. L. Lewis, treasurer of the Institute, showed slides illustrative of the recent damage to Stonehenge.—A paper was read on Malay metal-work, by Mr. Walter Rosenhain. The paper dealt with some specimens of Malay metal-work submitted to the author for microscopic and other examination by Mr. W. W. Skeat.—Some Malay processes actually witnessed by Mr. Skeat were described, and the bearings of the microscopic examination on the explanations of these processes were discussed. The first question dealt with was the production of the "damask" pattern on a Malay kris. Microphotographs were given showing that the "damask iron" really consists of layers of loosely welded wrought iron, the only other metal used being tool steel. The body of the blade is made of steel and a layer of laminated "damask iron" is welded upon either side of the central layer of steel; a thin layer of steel is welded on outside the "damask iron." The author believes that the striated "damask" effect is due to the opening of the loose welds in the damask iron during the forging of the blade, steel being driven between the laminæ. The outside layer of steel is entirely ground away, and when the compound surface so produced is "etched" by the pickling process employed, the more readily corroded steel is attacked, leaving the edges of the layers of iron as a series of narrow projected ridges.—The final section of the paper dealt with the Malay method of producing chains by casting, and was illustrated by some successful experiments.

Mathematical Society, February 14.—Dr. Hobson, F.R.S., president, in the chair.—Dr. Larmor, F.R.S., gave an abstract of a paper by Mr. T. Stuart, entitled "The Distribution of Velocity and the Equations of the Stream Lines, due to the Motion of an Ellipsoid in Fluid Frictionless and Viscous."—Lieut.-Colonel Cunningham communicated a paper on factorisable twin binomials. Mr. C. E. Bickmore spoke on the subject.—Mr. Tucker gave an account of the brocardal properties of some associated triangles.—The following papers were communicated by the president: Concerning the Abelian and related linear groups, by Dr. L. E. Dickson.—A geometrical theory of differential equations of the first and second order, by Mr. R. W. Hudson.—A note on stability, with a hydrodynamical application, by Mr. Bromwich.—Remarks on notation in Lie's theory of groups, and on Schur's determination of a continuous group of given structure, with remarks on Mr. Campbell's paper (read at the January meeting), by Mr. H. F. Baker, F.R.S.; and a note on curves similar and parallel to one another, by Mr. D. B. Mair.

CAMBRIDGE.

Philosophical Society, February 4.—Prof. Macalister, president, in the chair.—Geometrical notes, by the Master of St. John's College. These notes give simple proofs of Halley's construction for the normal or normals from a given point to a parabola, and Frégier's theorem that a chord of a conic which subtends a right angle at a fixed point of the curve passes through a fixed point on the normal thereat.—On the interference bands produced by a thin wedge, by Mr. H. C. Pocklington. The interference bands produced when monochromatic light from a small but finite source falls obliquely on a thin wedge of slightly reflecting material are investigated. It is shown that if the incident light is a parallel beam, the bands do not lie in the wedge, but in the air in a plane passing through the edge of the wedge and perpendicular to the reflected light, and that the distance between consecutive bands is $\lambda/2a$.—On some rare and interesting fungi, collected during the past year, by Prof. Marshall Ward.—On geotropism, by Mr. F. Darwin. The experiments described were directed to the question whether or not the tip of the root is the region where the gravitation stimulus is perceived. The germinating seeds were so placed that the tip of the root was fixed in the horizontal position, while the base of the root together with the seed could move. Since the supposed sensitive region remains horizontal, it was expected that the motor region of the root would continue to curve in response to the continued stimulation of the tip. This was found to be the case. But the great technical difficulties of the method and certain difficulties of interpretation render the evidence less striking than might have been hoped.—Notes on artificial cultures of Xylaria, by Miss E. Dale (communicated by Prof. Marshall Ward). Two species were cultivated from ascospores and grew equally well on pieces of the sterilised wood of beech, oak and silver fir, on which they produced several types of conidiophores.—The mycelium penetrates into all the tissues of the wood which forms its substratum, passing from cell to cell through the pits. Its action on the wood fibres is peculiar. Straight hyphæ pass down the lumen and give off branches which penetrate the pits and grow spirally, each lying in a channel which it has made in the cell-wall, apparently by excreting some wood-destroying enzyme.—The habits and development of some West African fishes, by Mr. J. S. Budgett. The paper gave an account of a part of the material obtained during a recent visit to the Island of McCarthy on the Gambia river, in order to investigate the development of *Polypterus*. The young larva of *Polypterus lapradii*, Steind., was described which had not yet developed the bony scales on the body. The nests and larvæ of *Protopterus annectens*, Ow., were described and the development shown to

be remarkably similar to that of *Lepidosiren*. The floating nests and the development of *Gymnarchus niloticus*, Cuv., were described and also the very large nests and the larvæ of *Heterotis niloticus*, Cuv. The larvæ of both these forms possess externally produced gill-filaments, while the development of *Gymnarchus* is in some respects shark-like. Two other forms, *Sarcodaces odoë*, Bl., and *Hyperopisus bebe*, Lacep., were shown to possess in the larval condition well-developed cement organs on the front of the head.—On a new form of microtome, by Mr. H. M. Leake (communicated by Mr. A. E. Shipley.)—The ignoration of coordinates, by Mr. T. J. I'A. Bromwich.—A theorem on curves belonging to a linear complex, by Mr. J. H. Grace.

DUBLIN.

Royal Dublin Society, December 19, 1900.—Prof. W. N. Hartley, F.R.S., in the chair.—Prof. E. A. Letts and Mr. R. F. Blake read a paper (communicated by Dr. W. E. Adeney) on a simple and accurate method of estimating the dissolved oxygen in fresh water, sea water and sewage effluents.—Mr. E. St. John Lyburn read a paper (communicated by Prof. W. N. Hartley) on prospecting for gold in the county of Wicklow, with an examination of Irish rocks for gold and silver. The author deals with the history of the discovery of gold in Ireland, and more especially with the results of a six months' prospecting tour in the county of Wicklow. One hundred and ten samples were taken and subjected to assay, the highest assay giving 4 dwts. pure gold per ton (2240 lbs.); this sample was obtained from a quartz vein, about eight inches wide, on the Croghan Kinshelagh mountain, and in the immediate vicinity of the Government workings of 1798. The author expressed the view that the locality he explored was worthy of further attention.

January 16, 1901.—Dr. W. E. Adeney in the chair.—Prof. Hugh Ryan read a paper on the preparation of amidoketones; and Prof. E. A. Letts and Mr. R. F. Blake communicated a paper on some problems connected with atmospheric carbonic acid, and on a new and accurate method of determining its amount, suitable for scientific expeditions.

PARIS.

Academy of Sciences, February 18.—M. Fouqué in the chair.—On a new form of the equations of mechanics, by M. H. Poincaré.—On the secondary radio-activity of metals, by M. Henri Becquerel. Metals receiving the direct rays from a radio-active substance appear to give off a secondary radiation. The penetrating power of this secondary radiation is more feeble than that of the primary rays, and is analogous to the same property of the secondary Röntgen rays discovered by M. Sagnac. The effect of this is that a metallic plate, placed upon a photographic plate, instead of acting as a screen to arrest the radiation from the source, gives, on the contrary, a stronger impression.—On a new gaseous compound, sulphuryl fluoride, SO_2F_2, by MM. Moissan and P. Lebeau (see p. 426).—On the alkyl cyanomalonic esters and the alkylcyanacetic acids derived from them, by MM. A. Haller and G. Blanc. It is shown that cyanomalonic ester contains the group CH, and that the substitution of alkyl radicles takes place on this atom of hydrogen, since in all the derivatives obtained from it the radicles are united to the carbon atom of the group CH.—Note on a congenital lacrymopharyngo-facial fistula, open below the left nostril, by M. Lannelongue. A description of a congenital fistula representing, in the form of an anomaly, a transition state in development. The case has an important bearing upon the theory of the development of the human embryo, and would appear to be in direct contradiction to the views of Albrecht on the development of the nose and upper lip. The operation described effected a complete cure.—On the discovery of a sea urchin of the Cretacean age in the eastern Sahara, by M. de Lapparent. The fossil described, which was found accidentally by Colonel Monteil at Zau Saghair, near Bilma, has been recognised by M. Victor Gautier as belonging to the same genus as an echinoderm discovered in the upper layers of the Cretacean in Baluchistan. It is thus proved that towards the end of the Cretacean epoch, about the time when in Europe the sea underwent such a marked retrogression, not only did it persist in the Lybian Desert, but it advanced to the neighbourhood of Tchad, manifesting by its fauna affinities with the Indian region.—On the propagation of waves in viscous fluids, by M. P. Duhem.—Observations on the variability of the planet 433 Eros, made at the Observatory of Toulouse with the 23-cm. Brunner equatorial, by M. F. Rossard.—On the luminous variability of Eros, by M. Ch. Andre (see p. 426). From the photometric observations, it is concluded that the planet is formed of a double system of two asteroids, of which the diameters are very nearly in the ratio of three to two, and whose orbital plane passes through the earth.—On the deformation of the paraboloid, by M. C. Guichard.—On the problem of the isoperimeters, by M. A. Hurwitz.—On functions of two variables analogous to modular functions, by M. R. Alexais.—On a new micrometer eye-piece, by M. L. Malassez.—On the specific absorption of the X-rays by metallic salts, by MM. Alexandre Hebert and Georges Reynaud. Results are given for experiments on the relative specific absorption of a series of metallic nitrates, from which it is shown that, in general, the absorption of the X-rays by the nitrates becomes greater with the increase in the atomic weight of the combined metal. The curve for the specific absorption plotted against the atomic weights as abscissæ is practically an equilateral hyperbola.—On hydrocinchonine, by MM. E. Jungfleisch and E. Leger. The substance previously obtained by the authors by the action of dilute sulphuric acid upon cinchonine and described by them as cinchonifine, is now shown to be identical with the hydrocinchonine of Caventou and Willm.—On diphenylcarbodiazine, by M. P. Cazeneuve.—On a new alcohol derived from limonene, by M. P. Cazeneuve. The new alcohol, named limoneol, is prepared by the action of peroxide of nitrogen upon limonene. It is a secondary alcohol, like pinenol, and gives a ketone on oxidation with chromic acid mixture.—The transformation of dimethylacrylic acid into dimethylpyruvic acid, by MM. Bouveault and A. Wahl. If the aminodimethylacrylate of ethyl, the preparation of which is described in a previous paper, is heated with aqueous hydrochloric acid, ethyl dimethylpyruvate is produced, the oxime and semicarbazone of which were prepared for the purpose of identification.—Action of the monohalogen acids of the fatty series upon pyridine and quinoline, by MM. L. J. Simon and L. Dubreuil.—On the pyrogallolsulphonic acids, by M. Marcel Delage.—The reserve hydrocarbon in the tubercles of *Arrhenathererum bulbosum*, by M. V. Harlay. The tubercles on extraction with dilute alcohol yield 4·8 per cent. of a carbohydrate, which on hydrolysis with dilute sulphuric acid gives pure lævulose. The original substance differs from inulin in solubility and rotatory power.—Nervous transmission of an instantaneous electric stimulus, by M. Aug. Charpentier. From the researches described it follows that an electrical stimulus may give rise to a double transmission on the part of the nerve, one part being transmitted nearly instantaneously, like an ordinary conductor, with a velocity too great to be measured in the usual way, the other part of the stimulus is transmitted, always electrically, with the very moderate velocity of about 20 to 30 metres per second.—The physiological action of wine, by M. L. Roos. From experiments on guinea-pigs the author concludes that the daily use of wine with the food, even in relatively large proportions, exerts no unfavourable effect.—The luminescence obtained with certain organic compounds, by M. Raphael Dubois. In presence of alcoholic potash a considerable number of organic substances become luminescent. The reaction may be of some service in the qualitative analysis of certain essential oils.—The nucleated red blood corpuscle behaves like a vegetable cell, from the point of view of osmosis, towards urea in solution, by M. R. Quinton.—On the absorption of monocalcium phosphate by arable earth and humus, by M. J. Dumont.—Observations relating to the propagation in apple orchards of *Nectria ditissima*, by M. Descours-Desacres. Nicotine, tannin and tannic acid have proved to be the most efficacious remedies against this disease.—On the petrographical province of the north-east of Madagascar, by M. A. Lacroix.—On a mass of metallic iron which was said to have fallen from the sky in the Soudan on June 15, 1900, by M. Stanislas Meunier.—Concerning the mineral layers of oolitic iron of Lorraine and their mode of formation, by M. Georges Rolland.

ST. LOUIS.

Academy of Science, January 21.—Rev. M. S. Brennan read a short sketch of the progress of astronomy in the United States, in which the material equipment and the discoveries made during the past century were passed in review.—A paper by Prof. T. G. Poats, entitled "Isogonic Projection," was presented in

abstract.—Prof. F. E. Nipher showed, by means of the lantern, a series of negatives printed by contact from a lantern slide or positive picture by the light of a 300-candle incandescent lamp. The unit of exposure adopted was one lamp-metre-second. The exposures varied from 0·0054 to 4800. All were developed in the dark-room with hydrochinon, those above 0·1 exposure having in the bath one drop of saturated hypo to the ounce of bath. The plate having an exposure of 0·1 seemed to be normally exposed. An exposure 210 gave a negative showing some fogging, but a print from it by ordinary methods gave a very satisfactory result. With longer exposures, the plate began to reverse, locally. With an exposure of 3600, which was an exposure of one hour at a distance of one metre from a 300-candle lamp, half of the plate still showed as a negative. The shadow on the gown of a figure in the landscape showed white as a negative, and the part of the gown in sunshine showed white as a positive. The penumbra between light and shadow was darker. All the details were sharp, but lights and shadows were somewhat incongruous. With an exposure of 4800 the details had not yet all reversed, but the greater part of the plate had become a positive. The greatest exposure giving a negative which would yield an acceptable print was 210, which was 39,000 times the least exposure which would give a good negative. All exposures of 210 and over gave complete positives when the plates were developed 1·41 meter from a 16-candle lamp, or in stronger light. As good a picture as has been obtained had an exposure of 4800, and was developed within half a meter of a 300-candle lamp. A fair picture had even been obtained from a two-hour exposure to direct sunlight with a Cramer "Crown" plate. It was stated that hypo in the developing bath did not affect the zero condition, or change the character as to positive and negative. When no hypo is used, the plate fogs so quickly that the picture is invisible before it has time to fully develop. After fixing, the thin shadowy picture showing on the fogged plate has the same local positive and negative characters that are shown on the clearly defined picture of the same exposure when developed in the hypo-hydrochinon bath. The greatest exposures giving good results that have been measured with reasonable accuracy were about 900,000 times as great as the least exposure giving a good negative in the dark-room. This factor can certainly be trebled. A plate having any intermediate exposure can be developed either as a good positive in the light or as a good negative in the dark-room.

DIARY OF SOCIETIES.

THURSDAY, February 28.

Royal Society, at 4.30.—On the Structure and Affinities of Fossil Plants from the Palæozoic Rocks. IV. The Seed-like Fructification of *Lepidocarpon*, a Genus of Lycopodiaceous Cones from the Carboniferous Formation: Dr. D. H. Scott, F.R.S.—A Preliminary Account of the Development of the Free-swimming Nauplius of *Leptodon hyalina*, Lillj.: Dr. E. Warren.—On the Result of Chilling Copper-Tin Alloys: C. T. Heycock, F.R.S., and F. H. Neville, F.R.S.—On the Theory of Consistence of Logical Class-frequencies, and its Geometrical Representation: G. Udny Yule.

Society of Arts, at 4.30.—Railways and Famine: Horace Bell.

Institution of Electrical Engineers, at 8.—Conclusion of discussion on Mr. Madgen's paper.—Followed, if possible, by Cables: M. O'Gorman.

FRIDAY, March 1.

Royal Institution, at 9.—Enamels: H. H. Cunynghame.

Geologists' Association, at 8.—The Post-Pliocene Non-Marine Mollusca of the South of England: A. S. Kennard and B. B. Woodward.—The Pleistocene Fauna of West Wittering, Sussex: J. P. Johnson.

SATURDAY, March 2.

Royal Institution, at 3.—Sound and Vibrations: Lord Rayleigh, F.R.S.

MONDAY, March 4.

Society of Arts, at 8.—The Bearings of Geometry on the Chemistry of Fermentation: W. J. Pope.

Victoria Institute, at 4.30.—A Visit to the Hittite Cities, Eyuk and Boghas: Rev. G. E. White.

TUESDAY, March 5.

Royal Institution, at 3.—The Cell as the Unit of Life: Dr. Allan Macfadyen.

Zoological Society, at 8.30.—On some Extinct Reptiles from Patagonia, of the Genera *Mioannia*, *Dinilysia*, and *Genyodectes*: Dr. A. Smith Woodward.—Note on the Innervation of the Supra-orbital Canal in *Chimaera monstrosa*: R. H. Burne.—Contributions to the Knowledge of the Structure and Systematic Arrangement of Earthworms: F. E. Beddard, F.R.S.

Institution of Civil Engineers, at 8.—Discussion of paper on the Rotatory Process of Cement Manufacture: W. H. Stanger and Bertram Blount.—Ballot for Members.

WEDNESDAY, March 6.

Society of Arts, at 8.—Modern Artillery: Lieut. Arthur Trevor Dawson.

Geological Society, at 8.—Recent Geological Changes in Central and Northern Asia: G. F. Wright.—The Hollow Spherulites of the Yellowstone and Great Britain: J. Parkinson.

Society of Public Analysts, at 8.—The Determination of Dissolved Oxygen in Water in Presence of Nitrites and Organic Matter: Dr. S. Rideal.—Some Analyses of Oatmeal: Dr. Bernard Dyer.—The Detection and Estimation of Preservatives in Milk: M. Wynter Blyth.

THURSDAY, March 7.

Royal Society, at 4.30.

Linnean Society, at 8.—A Contribution to the Fresh-water Algæ of Ceylon: Messrs. W. West and G. S. West.—On Mediterranean Malacostraca: A. A. Walker.

Institution of Electrical Engineers, at 8.—Insulation on Cables: M. O'Gorman.

Chemical Society, at 8.—(1) Nomenclature of the Acid Esters of Unsymmetrical Dibasic Acids; (2) Additive Compounds of α- and β-Naphthylamine with Trinitrobenzene Derivatives; (3) Acetylation of Arylamines: J. J. Sudborough.—Formation of Amides from Aldehydes: R. H. Pickard and W. Carter.

Röntgen Society, at 8.—Exhibition of Skiagrams and Apparatus.

FRIDAY, March 8.

Royal Institution, at 9.—Vitrified Quartz: W. A. Shenstone, F.R.S.

Royal Astronomical Society, at 5.

Institution of Civil Engineers, at 8.—Sewage Treatment: C. Johnston.

SATURDAY, March 9.

Royal Institution, at 3.—Sound and Vibrations: Lord Rayleigh, F.R.S.

CONTENTS.

THURSDAY, MARCH 7, 1901.

THE PRESENT ASPECT OF SOME CYTOLOGICAL PROBLEMS.

The Cell in Development and Inheritance. By E. B. Wilson, Ph.D., Professor of Zoology, Columbia University. Second edition, revised and enlarged. Pp. xxi + 483. (New York: The Macmillan Company. London: Macmillan and Co., Ltd., 1900.) Price 14*s.* net.

DURING the few years which have elapsed since the appearance of the first edition of Prof. Wilson's book on the cell, the rapid accumulation of new facts has resulted in the modification, in many important respects, of the views which were entertained concerning many cell phenomena even so lately as five years ago. Hence, though the volume before us is issued as a second edition, it has not only been considerably enlarged, but also much of the original matter has been displaced to make room for new treatment which shall more faithfully reflect the attitude of cytologists towards the problems which confront them at the present time. And we may fairly say that the author's efforts have not only been largely successful, but they have resulted in the production of one of the best works which it has been our good fortune to meet with for a long time.

The whole subject is handled in an easy and masterly fashion, and the reader is enabled readily to grasp the leading facts and to obtain a clear insight into the nature of the chief questions of cytological importance. Of course the book is not without its faults, but they are not, for the most part, serious ones. The author is naturally less at home when dealing with botanical than with zoological work, and indeed he says as much in his preface; but we notice, here and there, slips which might have been easily avoided. Amongst the most obvious of these is a somewhat misleading account of the morphology of the embryo-sac on pp. 264-5. A more trifling matter is the rather irritating recurrence of eulogistic adjectives, and the reader is apt to weary of a "brilliant" hypothesis or an "interesting" observation which is shown a few lines farther on to be untenable or unsound.

The volume opens with a brief historical introduction, in which it is satisfactory to find that to Cohn is given the credit, which undoubtedly belongs to him, of having been the first clearly to identify sarcode with protoplasm. Then follow chapters on the division of the cell and the nucleus, and of the more intimate structure of the cell-constituents. In the account of the details of karyokinesis, a fairly representative series of examples is given; but we could have been well contented had the author seen fit to amplify his treatment of the simpler and more primitive forms of life, seeing that so many of them exhibit remarkable and suggestive deviations from the course of events as pursued in the higher animals and plants.

Prof. Wilson deals with the vexed questions which have arisen concerning the centrosome in a cautious and discriminating manner, and he discusses the various theories which have been put forward respecting the nature and functions of this highly enigmatical body. A considerable mass of evidence has been gradually accumulating which tends to show that a greatly exaggerated importance has been assigned to it by many investigators. There are instances in which it can only be recognised as a transitory structure which persists during special phases of activity, to disappear when these subside. The view was at one time current amongst the majority of cytologists that the centrosome represented a permanent structure which presided over the divisions of the nucleus, and that it was, in fact, *par excellence* the organ which aroused and directed the karyokinetic processes. More extended investigation has, however, failed to support this proposition, and in not a few cases, especially amongst the higher plants, there is no good evidence of the existence of a centrosome at all. Furthermore, the researches of Hertwig, Morgan, and especially the recent ones of Loeb, have proved that eggs in which the original centrosomes have undergone complete degeneration are yet capable of exhibiting the entire processes of division when appropriately stimulated, and this without the entrance of a sperm or any other centrosome-bearer whatsoever.

The question as to the permanence of the chromosomes is also considered, and, on the whole, Prof. Wilson appears to incline to the view that the *same* chromosomes which were visible in the daughter nuclei at the close of a division reappear when the latter proceed to divide once more. In conformity with this idea, he supports the hypothesis that in cases where less than the normal number of chromosomes arise in a nucleus, these are in reality plurivalent—that is, each apparent chromosome is compound, and represents two (or more) true chromosomes united together, although their individuality may be for the time entirely masked. Thus it is well known that the nuclei of both the ovum and the spermatozoon possess only half the number of chromosomes characteristic of the somatic cells of the organism, and that this "reduction" is accomplished in connection with two peculiar and rapidly-succeeding nuclear divisions. Each of these chromosomes (at least in the first division) is then regarded as plurivalent (bivalent)—that is, as composed of, at any rate, two individuals which have not separated from each other. One necessary consequence of this view is that somewhere during one of these divisions, or at any rate before the formation of the sexual cells which arise from them, there must be a *qualitative* distribution of the real primary chromosome-individuals between two nuclei. Such an occurrence was regarded as antecedently probable by Weismann, and his views received a remarkable confirmation at the hands of several investigators, who describe the sequence of events as proceeding in a manner such as to render it apparently clear that a qualitative distribution does actually occur.

On the other hand, many others have been unable to find any evidence for the existence of such a type of division in other organisms, and conclude that the facts are strongly opposed to it. Should their view be correct, even in the case of a single example, the whole objective

 U

evidence relied on by those who see in the phenomenon of chromosome-reduction a confirmation of Weismann's theory falls to the ground. And with it, also, the hypothesis of plurivalency and continued persistence of the chromosomes suffers a serious limitation, for it is obvious that a time must soon arrive, in the sequence of generations, at which the evident chromosomes themselves can no longer consist of the telescoped chromosome units of all the previous life-cycles. In short, each chromosome that appears after the reduction in number cannot be represented in terms of the somatic units as $a+b$, but it must possess a new structure c.

Prof. Wilson very fairly reviews the evidence for and against a *qualitative* reduction (of the quantitative or numerical reduction there is, of course, no question), leaning, as has been said, somewhat in its favour, and it must be admitted that there is some indirect evidence in support of it. Perhaps it hardly falls within the scope of the author's work, but a consideration of the reversion of hybrids to the original stocks, such as indicated by Mendel's law, which has recently formed the subject of important communications by De Vries and by Correns, might have been discussed in this connection.

Exigencies of space forbid us to do more than to indicate the excellence of the treatment of the structure and development of the spermatozoon, of the phenomena of fertilisation, and of parthenogenesis. Our views as to the essential nature of fertilisation are undergoing a change in certain respects as the result of cytological investigations in this field of inquiry. We have clearly to recognise the existence of two distinct factors in the process. The one is concerned with the stimulation of the egg, which is thereby impelled to segment and to develop into a new organism, the other is involved in the fusion of the two sexual nuclei.

Boveri's experiments long ago showed that a fusion of the male and female nuclei was not essential to the segmentation and organised development of an egg. He succeeded in fertilising non-nucleated fragments of echinoderm eggs with the sperms of another species, with the result that larvæ exhibiting the paternal characters only were formed. These experiments were for some time regarded as not being free from objection, but they have been repeated with similar results. Again, as Loeb has recently shown, it is possible, by treating the unfertilised eggs of *Arbacia* with a solution of magnesium chloride, to cause them when replaced in sea-water to give rise to normal larvæ. And once more, Nathansohn has proved that, in the case of *Marsilea*, a sufficiently high temperature suffices to excite parthenogenetic development in the oospheres of these plants. Even in many normally fertilised eggs it has been repeatedly shown that the stimulus which starts the karyokinetic processes in the egg comes from the cytoplasmic (centrosome) portions of the sperm rather than from its nucleus.

As regards the significance of the nuclear fusion, although we are as yet unable to speak with certainty as to its proximate or efficient cause, there can be little doubt but that its teleological significance is to be sought in the fact that these bodies contain in themselves the physical basis of heredity, and thus by their coalescence the hereditary qualities of both parents are mingled in the offspring.

J. B. FARMER.

METHOD IN PHILOSOPHY.

Die Transzendentale und die Psychologische Methode. Dr. Max F. Scheler. Pp. 181. (Leipzig: Dürr'schen Buchhandlung, 1900.) Mk. 4.

IN opposition to the positivism which avers that if we take care of facts method may be left to take care of itself, Dr. Scheler claims that the history of thought, its continuity notwithstanding, shows abundantly that each fresh conquest in knowledge is preceded by a definite, if often half-conscious, breach with outworn method. Kant's historic mission has been fulfilled, and, after a century's probation, the time has arrived to pass beyond him. Not, however, by the adoption in philosophy of that psychological method which, discredited in Condillac and Hume, has been encouraged by recent advances in technical psychology to essay rehabilitation in more plausible forms. Dr. Scheler is with contemporary psychology in its reaction in favour of real as against formal principles, development as against finality, the historical as against the mathematical temper. He is with the Kantian in his recognition of the *quaestio juris* and in his advocacy of an inverse or "reductive" method. In the result he accepts a formula from Eucken—that of a regress from "the well-founded phenomenon" of a culture embodied in a coherent aggregate of institutions to the real forces of which it is the living and still growing product. *Arbeitswelt* and *Geistige Lebensform* are the catchwords of this "noölogical" method.

Dr. Scheler's discussion of "transcendental" method, *i.e.*, the inference from an accepted group of facts to the principle which can and can alone explain them—what evidence of the "alone" could be adduced it is hard to see—directs its main attack, not against its inverse character, but against (1) its static nature due to acceptance of an immutable starting-point, (2) its formalism in its conclusion to grounds of a merely logical kind, (3) its intellectualism with its consequent neglect of "three-fourths of life." Its alleged "synthetic propositions *a priori*," *i.e.*, propositions at once instructive and necessary, are really experiential. The starting-point is really dependent on psychology. Change the period and get a different psychological "climate," and you will find that the transcendental presuppositions will be different. But if so, the psychological ground-propositions will be complete in themselves, and formal conditions established by transcendental deduction are superfluous. The only regress which is not simply a doubling of the data must be towards real, that is, actual and active principles. And the data are neither unchanging nor purely rational.

This general appreciation Dr. Scheler reinforces by a detailed treatment of space, time, causation, and personality. As regards space, the temptation to strengthen the charge of formalism by putting Kant out of touch with a perceptual world has proved too strong for Dr. Scheler. Kant's "empty" space probably means only that all particular contents of space can severally be thought away without altering our space-apprehension. Kant's space is voidable rather than void. Geometer's space, while it is in one sense an abstraction, is not only not a generic concept, but not a concept at all, if the argument as to whole and parts in Kant's metaphysical exposition is to stand. The psychogenetic problem of the perception of a third dimension is irrelevant to Kant's nativism.

The bearing of "metageometry" upon Kant's doctrine of space is still *sub judice*. It is open to the Kantian to maintain either that "bent" spaces fall within Euclidean space, multidimensional spaces being an hallucination due to abuse of algebraic symbolism, or, with Mr. Bertrand Russell, that if Euclidean space is experiential, yet some "form of externality" is *a priori*. Dr. Scheler is, however, throughout the discussion suggestive, if inconclusive.

Less satisfactory is his treatment of causation. The statement that the conception of uniformity is foreign to the Greek period is absurd. That the period of Roman decay was one of lawless happenings is not true in the sense of p. 73, and Dr. Scheler does not save himself by after qualification, in view of the exaggerated position of p. 69, that the causal category which makes natural science possible as a science of experience would make historical science as a science of experience impossible. The treatment of time and the self is relatively slight.

The inadequacy of the psychological method is to be found in its equivocal use of the term "facts of consciousness." Either it is Protagorean and anarchical, and the objects of all sciences and nesciences are on a dead level of "psychical existence," or there are realities which transcend this accommodating rubric. Idealism is prone to the epistemological fallacy, as positivism is prone to the phenomenalist fallacy.

If, however, neither transcendentalism with its reduction, nor psychology with its grip on something real—even falsities—can satisfy us, we must, in default of other probable courses, cast about for some syncretist formula uniting the truths and discarding the defects of both. Dr. Scheler declines Sigwart's irenicon, because of the primacy it involves of the moral and volitional element in life. Surely this is not ineradicable from Sigwart's formula? Rejecting this, and the solutions of which it is the type, he falls back upon the endeavour of his teacher, Eucken, to make jettison of all in both methods that offends the time-spirit, and to fashion what is left, with the aid of something which both had left out, into a non-absolutist, non-sceptical scheme, hereafter to be more fully developed.

H. W. B.

OUR BOOK SHELF.

First Stage Botany, as Illustrated by Flowering Plants. By Alfred J. Ewart, D.Sc., Ph.D., F.L.S. Pp. viii + 252. (London: W. B. Clive and Co., no date).

THE author sets forth in the preface that his primary object in writing this book was that of satisfying the requirements of students preparing for the elementary stage of the Science and Art Examinations. A glance through its pages suffices to prove that this end is everywhere kept to the fore. Even the figures, which are very numerous, are labelled all over in large type so as to enable the student, with the minimum expenditure of time and trouble, to get up the maximum amount of facts. In the text the treatment is on analogous lines, and probably the student possessed of a good memory might, with this book as his mentor, succeed in passing a fair examination. Beyond this we have failed to discover why the book was written; and when its author goes on to state that it is also intended to serve as an "efficient introduction to Botany," we simply cannot agree with him. The character of the book is too dogmatic, and too little is left to the student. Indeed, a sentence contained in the preface, advising the student to obtain specimens and "verify upon them the statements made in the text," gives the key to the entire book. Not merely verification, but the fostering of a spirit of *inquiry* ought to be the chief aim of a teacher, and it is this aspect of the matter which we miss in the volume before us. In the paragraph on geotropism (p. 211) this phenomenon is defined as the "tendency of the radicle or main root to grow towards the centre of the earth"; a very inadequate definition both from the point of view of fact and theory, and one of little or no scientific value to the student.

Some subjects, *e.g.* obdiplostemony, are introduced which would have been better omitted. Unless fully discussed they are of no value educationally, and the space they occupy would be better taken up by a more extended treatment of the more elementary matters. Although, in a general way, the book much resembles others of its class, save, perhaps, in the compression of an unusually large number of facts into its pages, it is but right to add that actual errors are remarkably scarce.

The Principles of Magnetism and Electricity. An Elementary Text-book. By P. L. Gray, B.Sc. Pp. xvi + 235. (London: Methuen and Co., 1901.) Price 3*s*. 6*d*.

THE number of elementary text-books on magnetism and electricity probably exceeds that of text-books on any other subject. One would, therefore, naturally expect that anybody attempting to add to their number would do so with a due sense of responsibility, and endeavour to produce a book which might be regarded as surpassing those already in existence either in accuracy of exposition or in freshness of treatment. A careful perusal of the book before us has forced us to the conclusion that the author is destitute of all sense of responsibility, and not afraid to scatter error broadcast with a light heart. Seldom has it been our lot to come across an elementary text-book so full of glaring errors so boldly stated. On p. 18 the author describes a vibrational method of comparing the moments of two magnets in which the moments of inertia of the magnets are not even referred to! On p. 15 we have the startling assertion that in the case of diamagnetic bodies "the induced magnetisation is *at right angles to the field*" (the italics are the author's!). Could there be a greater confusion of ideas than that exhibited by the following sentence? (p. 151): "A pole of strength m will have $4\pi m$ lines of force proceeding from it, so that, if a transverse narrow cut be made across a magnet which has σ lines per sq. cm. in any normal cross-section, the field in the narrow slit H will be equal to $4\pi\sigma$." The author measures magnetic force in *dynes*, and difference of potential in *ergs*. On p. 162, in connection with the induction coil, we read: "Trowbridge has recently obtained sparks nearly seven feet in length, obtaining an E.M.F. of 3,000,000 volts, *the primary current being supplied from a battery of* 10,000 *storage cells*" (the italics are ours). Is the author serious, or does he intend playing a practical joke on his reader, by suggesting that any sane person would use 10,000 storage cells for supplying the primary of an induction coil? Had he taken the trouble to refer to Prof. Trowbridge's papers, the author would have found that the arrangement used for obtaining the 3×10^6 volts had nothing whatever to do with an induction coil. On p. 163 we have the sentence: "The total value of the magnetic force within a circuit is known as the magnetic *flux* through the circuit." Now, what does the author mean by "the total value of the magnetic force within a circuit"? When touching on technical matters, the author does not scruple to make various erroneous statements with an airy assumption of superior knowledge. "Theoretically," we are told on p. 166, "every dynamo could be used as a motor and every motor as a dynamo. In practice, however, this power of reversibility is not used." Again, on p. 170, we read: "Owing to the self-

induction of each section of the armature, a certain amount of energy is used twice in each revolution to establish the current in it. *This energy is lost* so far as the external circuit or the effective output of the machine is concerned" (the italics are ours). This sentence shows that the author has never attempted to study the extremely complicated problem of commutation; it would, therefore, have been wiser to say nothing about it in an elementary text-book.

But we must stop, though we have by no means exhausted the various errors which mar the book. We have noted a few quite as glaring as those which have been adduced as samples. The book possesses some good features, notably the attempt to explain everything by considering the stresses in the medium; but it is so full of error that we feel bound to condemn it very strongly.

A. H.

Die Lehre vom Skelet des Menschen unter besonderer Berücksichtigung entwickelungsgeschichtlicher und vergleichend-anatomischer Gesichtspunkte und der Erfordernisse des anthropologischen Unterrichtes an höheren Lehranstalten. Bearbeitet von Dr. F. Frenkel. Pp. vi + 176. Mit 81 textfiguren. (Jena: Gustav Fischer, 1900.)

THE author has in course of publication, for use in the Gymnasia and Realschulen, a series of wall plates in which the anatomy of the human body is represented, and he has prepared the book now under consideration as a supplement to the plates which illustrate the skeleton. He devotes 176 pages to the description of the human skeleton, and includes an account of the joints which connect the bones with each other. He has adopted as the basis of his arrangement the plan followed by Gegenbaur in the "Lehrbuch der Anatomie der Menschen."

In the course of his description, Dr. Frenkel takes the opportunity of calling attention to the developmental changes which take place in the præ-ossific stage of the skeleton, as well as during the process of ossification itself, more especially in their bearing on the production of variations which, from time to time, come under the notice of anatomists. He contributes an interesting chapter on the variations in the number of vertebræ, more especially in the thoracic, lumbar and sacral regions, and explains the occasional occurrence in the dorsi-lumbar region of a vertebra which partakes partly of the characters of both these groups, and in the lumbosacral region of a vertebra which exhibits a transitional form between the lumbar and sacral series.

The opportunity is taken, from time to time, to point out the differences in arrangement and character between the human skeleton and that of the anthropoid apes, though in this respect many additional examples might readily have been given. It is, of course, impossible in a work of this kind to free the descriptions from technical terms and modes of expression; but the author, taking into consideration the class of readers for whom it has been written, has explained the meaning of the terms and, as far as practicable, has couched his descriptions in language to be readily apprehended.

De Paris aux Mines d'Or de l'Australie occidentale. By O. Chemin. Pp. 370 + 2 maps. (Paris: Gauthier-Villars, 1900.)

A DESCRIPTION of Western Australia from the mining point of view, illustrated with pictures characteristic of the scenes presented in a journey from Paris to Perth, and examined during short visits to other places in our premier gold-producing colony. The geography, population, government, mineral resources and gold fields of the colony are surveyed, and the condition and promise of individual mines commented upon. The author spent nearly a year in Westralia, and his book will direct the attention of his countrymen to an immense region, much of which is still little known.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Malaria and Mosquitoes.

INTERESTING letters by Mr. D. E. Hutchins and Mr. F. R. Mallet have recently appeared in NATURE, suggesting the possibility of there being some other route for infection in malaria besides that by the bite of Anopheles. Suggestions of this kind always appear to me to give rise to the questions, (*a*) whether the facts are really as stated? and (*b*) whether, if even this is the case, they cannot be explained by the mosquito theory? The notion that clearing jungle causes fever is very widely spread; but this does not prove that it is true. Granting that it is true, it may possibly be explained on the ground (*a*) that persons engaged in clearing jungle and laying out new plantations are not likely to be so well housed as those who live in established settlements; (*b*) that any hard labour encourages relapses of fever among coolies and others who have already been infected; and (*c*) that, as shown by Christophers and Stephens, jungle often contains large numbers of Anopheles. The frequent statements one sees, to the effect that malaria has prevailed largely when mosquitoes were few, are generally too vague to be of value, because it is not added whether the cases were relapses or fresh infections, or to what kind the "few" mosquitoes present belonged. When a man says that mosquitoes are numerous he generally refers to the genus Culex, which probably assert themselves more than do Anopheles. The idea that the water of the rivers of western India can cause fever when it is drunk is certainly opposed to my personal experience. In 1891 I went fishing with Mr. G. Tait, of Bangalore, in the River Bhawani, near Ootacamund. I remember that at the time I did not think that fever could be acquired by drinking such water, and I used daily to drink the unboiled water of this river (which flows amongst thick jungle). I remained quite free from fever, without taking quinine; but Mr. Tait was afterwards attacked. So far as I remember (but I am not sure), he had refused to drink Bhawani water; but I am not certain that his fever was malarial. Again, the idea that malaria is absent in the Nilgiri Hills round Ootacamund unless the soil is turned does not accord with my personal experiences. I acquired fever at Kalhutti (5000 feet above sea-level) in 1897, when I was investigating the disease in the Sigur Ghat. I thought at the time that I had acquired it in the plains below, but, in the light of our present knowledge, have little doubt that I became infected in the dak-bungalow at Kalhutti, where a succession of kitmutgars and their families had been taken ill. I noted particularly at the time that there was no freshly turned soil in the neighbourhood of the bungalow. Lastly, the case mentioned by Mr. D. E. Hutchins, namely that of a medically authenticated case of malaria being produced by fresh earth carried past a window in baskets by coolies, seems to me to be open to criticism. *Which* fact was medically authenticated—the fact that the patient suffered from malaria, or that his malaria was caused by the earth carried past in baskets? I can understand the first fact being certified by a doctor, but scarcely the second. How did the doctor prove that the fever was produced by the earth in the baskets? It seems to me that the only way in which he could have done so in a trustworthy and scientific manner would have been to infect a second person by having the baskets carried past a second time. I doubt whether such instances—and we see hundreds of them in the Press—will bear close examination. Those who cite cases of fever apparently due to freshly-turned earth, seem to forget that there are millions of people constantly engaged in digging without suffering from the disease more than others do.

Liverpool, February 25. R. ROSS.

Abundance of Peripatus in Jamaica.

MR. P. H. GOSSE in the "Naturalist's Sojourn in Jamaica" (p. 66) makes the first reference to the occurrence of Peripatus in Jamaica, having found in 1845 five or six specimens, near Bluefields, on the south-west coast of the island. Gosse regarded them as "rather allied to the Annelida than to the Mollusca." No further mention of the animal is made until it was rediscovered at Bath in 1892, nearly fifty years after, by a local naturalist, Mrs. Swainson. Seven Peripatus were sent to

the museum of the Institute of Jamaica, and later were briefly described by Messrs. Grabham and Cockerell in NATURE (1892, p. 514), when the specific term *Jamaicensis* was suggested. The year following over a dozen specimens were received by Dr. Grabham, also from Bath. The locality is in a most humid part of the eastern extremity of the island. Two or three examples have since been secured from widely separated spots, but the species has hitherto been regarded as one of much rarity, and as uncertain in its distribution. Various attempts made by different collectors to secure specimens have been unsuccessful.

Prof. E. L. Bouvier, who has lately been making a systematic study of the genus, recognises two species—*P. jamaicensis* and *P. juliformis* var. Gossei—among the Jamaica representatives, (cf. *Quart. Jour. Micr. Sci.*, vol. xliii. p. 750). Prof. Ray Lankester, on behalf of Prof. Bouvier, has recently communicated with the Institute of Jamaica asking for additional specimens. A general description of Peripatus was accordingly inserted in the local newspapers, and offers of reward were made with the object of encouraging the peasantry to search for the animal, but this was of no avail. A visit, since made by the writer, to Bath resulted in the securing of a number of examples. These were exhibited in the neighbourhood and a sum was offered for further specimens, with the result that before long numbers began to pour in and soon upwards of fifty were obtained. Dr. Grabham also secured a large supply. Afterwards more than eighty specimens were dispatched to the Museum, then another fifty were offered, and now that a local enthusiasm has been created it would seem that examples in plenty might be procured at any time. It is thus obvious that the animal is by no means so rare as has been supposed.

The creatures are found under stones and rotten wood, often buried for a short distance in the earth. Most are blackish brown or green, much lighter on the ventral surface; others are reddish black above and light flesh-coloured beneath; but many intermediate tints occur. A reddish-brown colour is extracted at first by alcohol, and the distinctive colours are soon lost. Specimens of all sizes were obtained, including individuals in which parturition took place during preservation. The length of the newly born was as much as 2 cm. J. E. DUERDEN.

Institute of Jamaica, Kingston, February 12.

Audibility of the Sound of Firing on February 1.

FROM the letters written to NATURE and to the *Standard* by correspondents who heard at very great distances the guns fired at Portsmouth on February 1, it seems to be the general impression that the firing was by volleys, if one may use a convenient but probably technically incorrect expression. This was not the case. It would be very desirable that the official order of firing should be published. If this is not done, there may be some interest in a note on the order as it appeared to me, watching from the sea-front near Southsea Castle.

The disposition of the fleet was roughly thus:

SOUTHSEA.

Channel Squadron.

Reserve Squadron. * *Flagship.*

Foreign ships.

OSBORNE.

The first gun of each round of firing seemed to me to be fired far down the line, from the flagship of the Reserve Squadron; but of this I cannot be sure. It was immediately succeeded by the gun from the *Majestic*, flagship of the Channel Squadron; and from this the firing ran down the double line, the intervals between the successive pairs of flashes being about half a second. It was impossible to see from Southsea whether the Reserve Squadron followed the lead of the Channel Squadron or of its own flagship. In the latter case, after the leading guns from the flagships there would have been four guns, in the former case two guns every half second, for a space of some seconds.

These details are from memory, and may require some correction. The important fact is that the guns were fired in quick succession, and not simultaneously.

The line of ships was about eight miles long, roughly east and west, and Southsea was about a mile north of the eastern end. But the roll of the guns lasted only about twenty seconds—that is to say, scarcely any sound reached us from the western division of the line, which was hidden from sight by a projecting point of land. It is not surprising, therefore, that nothing was heard at Chichester and other places comparatively near Portsmouth. ARTHUR R. HINKS.

Cambridge, February 26.

Protective Markings in Animals.

I ENCLOSE a photograph of my cat asleep, in which may be plainly seen the resemblance to open eyes, borne by the markings above the orbits. In the living cat this resemblance is so striking that my attention was first drawn to it by my fancying that he was sleeping with his eyes open.

I have noticed the same markings in other cats, but never quite so distinct. The advantages, to a non-domesticated animal, of such an arrangement are obvious, and I think it may interest some of your readers. Besides these marks over the eyes, I observe in a good many cats that the fur on the lower jaw is generally light and bounded by markings following the line of the mouth, thus giving a heightened effect when open, whilst when shut, during sleep, the cat has, at a distance, the appearance of having the mouth still open. CLARENCE WATERER.

Highfield, Northdown Avenue, Margate, February 26.

Snow Crystals.

A FALL of snow stars, similar to that described by Mr. Wm. Gee (p. 420), occurred near Sutton Coldfield about 1876, as near as I can remember. I was much struck by their beauty and the graceful way they fell to the earth. C. J. WOODWARD.

Municipal Technical School, Birmingham, March 2.

THE NEW STAR IN PERSEUS.[1]

DR. COPELAND was kind enough to inform me by telegram, on the afternoon of February 22, of the discovery by Dr. Anderson of a new star in the Milky Way in Perseus on the early morning of that day. It was stated that its position was R.A. 3h. 24m. 25s. and Declination $+43^{\circ} 34'$, its magnitude 2·7, and colour of a bluish-white. Later in the evening this information was corroborated by another telegram from the "Centralstelle" at Kiel.

Owing to cloudy weather, no photographs could be obtained at Kensington until the evening of the 25th. Momentary glimpses of the star on the evening of the 22nd, between the hours of 6 and 7.30 p.m., indicated that the Nova had considerably brightened since the time of its discovery, as it was estimated as a little brighter than a first magnitude star; no satisfactory observations of the spectrum could be made.

Another glimpse on the early morning (1.30 a.m.) of Monday (25th) showed that the star was still of about the first magnitude.

Prof. Pickering reports that the Nova was dimmer than an eleventh magnitude star on February 19. On the 23rd it was as bright as Capella.

The star, therefore, was then at least 10,000 times brighter than it was four days previously, and ranks as the brightest new star recorded since that which appeared in the year 1604.

Since the 25th the brightness has diminished slightly, and on the evening of the 27th was estimated between the first and second magnitude (1·7). If this reduction of brilliancy continues at the same rate, the new star will evidently be shorter lived than those to which it has most closely approximated in luminous intensity at the maximum, and less time will be available for studying the spectral changes which may be anticipated. I may state that Tycho's Nova (1572) was visible for nearly one and a half years, and Kepler's (1604) for about the same period.

It is interesting to note that the star was described by Dr. Anderson as being of a bluish-white colour at the

[1] Preliminary note. By Sir Norman Lockyer, K.C.B., F.R.S. Received and read before the Royal Society, February 28.

time of discovery. Since it has diminished in brightness this has changed, and on the night of February 27 a reddish tinge was observed.

Although the sky on Monday evening was by no means free from clouds, ten very satisfactory photographs were secured with the three instruments in regular use for stellar spectra. Edwards's isochromatic plates were used, as it was considered desirable to secure a record of the green part of the spectrum.

Although there has not been time for a complete discussion of these photographs, it may be stated that the spectrum contains numerous dark lines, several of which are associated with bright bands on the less refrangible side. Further, the spectrum, as a whole, greatly resembles that of Nova Aurigæ.

One of the chief features of the principal bright lines is their great width, amounting to 30 tenth-metres, and each is accompanied by a dark line of considerable breadth on its more refrangible side. A comparison spectrum of γ Orionis, photographed alongside that of the Nova on one of the plates, indicates that the middle portions of the bright lines are not far from their normal positions; those of the dark ones, however, are displaced by some 15 tenth-metres towards the violet, thus indicating a differential movement of something like 700 miles a second.

Movements more rapid and disturbances more violent than those observed in Nova Aurigæ are therefore indicated; both by the greater displacement of the dark lines relatively to those that are bright and the greater breadth of the bright and dark lines.

tested by inquiring whether other prominent enhanced lines of iron so strongly visible in the spectrum of α Cygni were present.

A comparison with the spectrum of this star photographed with the same instruments suggested that many lines between F and *h* in the Nova probably correspond with lines in α Cygni. Certainty could not be arrived at in consequence of the great breadth of the lines in the Nova.

Hence, as the Nova bore some resemblance to both Nova Aurigæ and α Cygni, a reference was suggested to the lines recorded in the spectrum of Nova Aurigæ which were observed when the light of that star was on the wane, and when the lines were thinned enough to be easily measurable. I may also add that these observations were made before the work on enhanced lines was undertaken.

The importance of this reference was strengthened by the consideration that with such a tremendous outburst we should expect the original invisible swarm to have been (very rapidly) advanced to a considerable condensation at the locus of impact, and therefore to resemble some "star" which had (slowly) arrived at a position pretty high up on the ascending temperature curve in the ordinary course of evolution on the meteoritic hypothesis.

A comparison of the bright lines recorded by Campbell[1] and Vogel[2] in the spectrum of Nova Aurigæ with the strongest lines of α Cygni—a very detailed record of the spectrum of which star has been recently compiled here—shows that there is a close agreement between the two sets of lines. These strong α Cygni lines are almost without exception the representatives of "enhanced" lines of some of the metals, chiefly Fe, Ti, Cr, Ni, Ca, Sr, and Sc. If we exclude the lines of hydrogen from those which were recorded in the spectrum of Nova Aurigæ, there remain forty-four lines for comparison. Thirty of these, or about 70 per cent., agree approximately in position with either strong isolated lines or groups of lines in the spectrum of α Cygni.

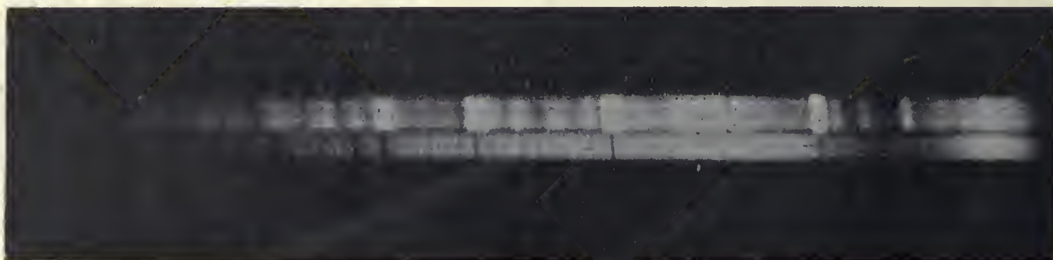

FIG. 1.—Spectrum of Nova and α Persei compared.

The comparison of spectra shows us that we are dealing with two swarms, one of which, the less dense, gives us broad bright lines and is almost at rest with reference to the line of sight; the denser swarm, indicated by the dark lines, is in most rapid movement in the line of sight towards the earth.

An interesting feature of the spectrum is the presence of fine dark lines down the middle of each of the bright lines of hydrogen and calcium; these are most probably reversals, and if this be so, they will be of great service for accurate determination of the wave-lengths of the other bright lines.

The dark hydrogen line Hγ, and perhaps Hβ and Hδ, are also possibly reversed.

Eye observations showed among the chief lines a group of four in the green; one probably Hβ, the others near λλ 492, 501 and 517; a bright line at or near D, and a brilliant red line probably corresponding to Hα. Each of these was accompanied by a dark broad line on its more refrangible side. Other lines of less brightness were observed both in the green and red.

It at first seemed probable that two of the bright lines in the green (λλ 492 and 501) might be due to asterium, while that in the orange was perhaps the helium line D_3. Subsequent investigation, however, suggested as an alternative origin that these lines might be the enhanced lines of iron at λ 4924·1 and 5018·6, which are very nearly in the same positions as the asterium lines. This view was

It may be assumed that, taking into consideration the broad nature of the Nova lines, if there be any genuine connection between them and the lines of α Cygni, any close groups of separately distinguishable lines in the latter spectrum would be thrown together in the Nova spectrum, and appear as broad bands. A good instance of this appears in Campbell's list. He records a band extending from λλ 4534 to 4501. In the spectrum of α Cygni there is a strong line at each of the positions given, and between them there occurs a strong quartet of lines. The former are well enhanced lines of titanium, and the latter of iron. It seems extremely likely, therefore, that the six lines thrown together produce the apparently continuous band observed by Campbell.

If the stage of α Cygni has really been reached, the following considerations come in:—

[1] *Ast.-Phys. Jour.*, vol. xi. p. 807, 1892.
[2] *Ast.-Phys. Jour.*, vol. xii. p. 912, 1893.

In the orderly condensation of swarms, according to the meteoritic hypothesis, the earlier stages are—

Ascending temperature.		
↑	Cygnian	Dark lines, corresponding chiefly with the enhanced lines of various metals.
	Polarian	Dark lines, comprising both arc and enhanced lines of various metals.
	Aldebarian	Dark lines, chiefly corresponding to those which appear in the arc spectra of various metals.
	Antarian	Mixed bright and dark flutings and dark lines. Bright hydrogen lines in those stars which are variable.
	Nebula	Bright lines.

In the case of new stars, after the maximum of luminosity has been reached, however high they ascend, short of the apex of the temperature curve, this order must be reversed, and hence we should expect to find the spectrum varying in accordance with the foregoing sequence, but in the reverse order.

In Nova Coronæ (1866), according to the observations of Sir William Huggins and Dr. Miller, the absorption spectrum was very similar to that of α Orionis, which is a star of the Antarian group, so that the temperature attained was relatively low; this, indeed, is demonstrated by the fact that at present it shines faintly as an Antarian star, and doubtless did so before the collision. The collision, therefore, probably did not take Nova Coronæ very much above its initial stage of temperature, and when the disturbance was over it simply reverted to its old conditions.

The spectrum of Nova Cygni (1876) was not photographed, and as special attention was given by most observers to the bright lines, there is no satisfactory record of the absorption spectrum.

This now appears as a nebula, and doubtless it was a nebula to begin with, as Nova Coronæ was a star to begin with.

In Nova Aurigæ (1892), as we have seen, the comparison with α Cygni indicates that the Cygnian (that is, a higher) stage was reached, and in the final stages its spectrum corresponded with that of the planetary nebulæ, that is, a stage lower than that reached by Nova Coronæ. The intermediate stages, however, were not observed, possibly because the star was never very brilliant, and partly because of the difficulty of observing closely grouped lines, such as occur in the Polarian and Aldebarian stages when they are rendered broad by such disturbances as those which were obviously present in the Nova.

The observed maximum magnitude in the case of a new star will evidently depend upon the distance and size of the colliding masses, as well as upon the temperature produced by the collision. It is not remarkable, therefore, that there is no apparent relation between the greatest brightness and the temperature indicated by the spectra. Nova Coronæ, with its relatively low temperature, shone for a time as a second magnitude star, while Nova Aurigæ, with a much higher temperature, scarcely surpassed a star of the fifth magnitude.

I now return to Nova Persei.

If the idea that in the present Nova the swarm which gives the dark line spectrum resembles α Cygni be confirmed, as its temperature is reduced we may expect it to pass successively through some or all of the stages of temperature represented by stars of the Polarian, Aldebarian and Antarian groups, enhanced lines being first replaced by arc lines and then by flutings. Whether it remains at one of these stages or undergoes a further backwardation into a nebula will be a point of the highest interest.

If, like Nova Aurigæ, the present Nova should end as a nebula, it will furnish a most convincing proof of the fundamental metallic nature of nebulæ.

In conclusion, I wish to express my thanks to Dr. W. J. S. Lockyer and Mr. F. E. Baxandall, of the Solar Physics Observatory, and to Mr. A. Fowler, of the Royal College of Science, who have greatly assisted me in preparing the present note, and who, with the addition of Mr. Butler, of the Solar Physics Observatory, secured the excellent set of photographs and eye observations on the night of the 25th, from which the new knowledge has been derived.

The preparation of the slides I owe to Mr. J. P. Wilkie.

Solar Physics Observatory, February 28.

RECENT SWISS GEOLOGY.

THE glaciers of the Alps have lost considerably in bulk during the last forty years. This began at rather different dates, for some were still advancing in 1860, while by 1870 the diminution was very marked. Since then there have been slight oscillations, but until lately loss, on the whole, has exceeded gain; now, perhaps, the tide has turned. The report on the Unter Grindelwald glacier, by Prof. A. Baltzer,[1] describes the changes this glacier has undergone during the abovenamed period, and the results of some special observations made between 1892 and 1897. It was unusually well suited for the purpose, for its changes had been very conspicuous, and they had been already more closely observed than in many other glaciers.

In 1858, as is shown in a photograph, the glacier descended to the level of the valley beneath Grindelwald, where the Weisse Lütschine, in the summer of that year, issued from an ice cave. By 1870 the glacier had retreated up the glen between the Eiger and the Mettenberg, exposing three great rocky steps, the existence of which, it may be remarked, is anything but a favourable testimony to the excavatory power of ice; and its thickness higher up had so much diminished that the writer looked down a cliff, fully sixty feet high, on to the surface very nearly at the place where he remembered stepping easily from the ice to the rock on his way from the Strahleck Pass. A photograph representing the state of the glacier in 1895, on which Prof. Baltzer has indicated its former extent, shows how great the change has been; the modern ice stream looking, by comparison, like a caterpillar crawling to hide its diminished head in a rocky gorge (Fig. 1). One remarkable effect of this shrinkage (as described by Mr. F. F. Tuckett in the *Alpine Journal*, vol. vi. p. 30), was to lay bare, in 1871, a quarry in a bed of mottled pale red and green marble, which had once been extensively worked, but for about a century had been completely hidden beneath the ice. By the retreat of the glacier large areas of ice-worn rock have been exposed, several of which are represented by photographs in Prof. Baltzer's memoir. From study of these he concludes that there are two forms of ice-erosion; one—the ordinary—smoothing or abrading of the rock surfaces; the other, a tearing and a splitting off of fragments in cases where the rock is much traversed by divisional planes. As he deems this to have been less generally recognised, he illustrates it by photographs. It is difficult without actual examination of the localities to form an opinion on this point. That the rock, chiefly from mechanical causes, is readily broken is beyond question; but, though the fragments thus formed would be more easily removed than from a solid mass, it is doubtful whether the ice plays more than a secondary part, so that the remark would be equally true of any other kind of erosion. Given an irregular surface, the friction of a body moving over it would tell upon the prominences; but probably more pieces fall away than are broken away.

[1] Vol. xxxiii., part 2, of the *Neue Denkschriften der Allgemeinen Schweizerischen Gesellschaft.*

The more minute observations on the changes in the volume of the glacier, which have been carried on from 1892 to 1897, prove constant variation, and suggest a connection with the prevalent temperatures. It is to be hoped these will be continued, for they will aid in the discovery of the causes to which the greater changes are due. The past history of the glacier shows a marked period of advance to have begun about the year 1600, reaching a maximum in 1620, after which it retreated. A strong advance set in at the beginning of the eighteenth century, and it attained a maximum just a hundred years after the former one, the ice then retiring. About 1743 it again advanced, but only for a short time, and this was followed by a marked retreat. But from 1770 to 1779 there was a great advance (which probably buried the marble quarry, and, so far as is known, hid it for nearly a century). But since then the oscillations have been considerable, for two periods of advance are recorded, one from 1814 to 1822, the other from 1840 to 1855, the effect of the latter remaining, as has been said, for four or five years. It is at present difficult to explain these singular changes of volume in the glaciers; very probably they are connected with both winter snowfall and summer temperature, but the former, as chiefly affecting the upper part of a glacier, may be some years before it produces an effect at the lower end, while that will be more immediately sensitive to summer warmth. Hence each glacier must be separately studied, as this one has been by Prof. Baltzer. The importance of the investigation is now generally recognised, and that not only in the Swiss Alps. In these, according to Dr. Richter (*Archiv. Genev.* vi. 1898, p. 22), of fifty-seven glaciers observed in 1897, fifty were still decreasing, five were stationary, and twelve were increasing, so that it will evidently be difficult to fix very precisely a date for the maximum and minimum of a whole region.

FIG. 1.—The Unter Grindelwald Glacier in 1895. The white lines show the extent of the glacier in 1858.

Other memoirs recently issued by the Swiss Society of Natural Science deal with various subjects. Vol. xxxvi. (1899), Part i. contains two memoirs. One, by Dr. M. Standfuss, "Experimentelle Zoologische Studien mit Lepidopteren," illustrated by five plates, is an investigation of the effect of temperature, either continuously higher or lower than the average, but within the possibilities of nature, upon the imago of lepidoptera, the pupa of which have been thus treated. The cold, speaking generally, seems to reduce the size of the imago and makes it paler in colour, the heat having the contrary effect. The second memoir, "Monographie des Genus Elaphoglossum," by Dr. H. Christ, illustrated by four plates, is an elaborate botanical study.

Vol. xxxvi. (1900), Part ii. also contains two memoirs. One is by Prof. Ed. Fischer, "Untersuchungen zur vergleichenden Entwicklungsgeschichte und Systematik der Phalloideen," illustrated by six plates and four cuts in the text, in which the relationships of the several forms are elaborately worked out. The other, by Dr. Emil Hugi, "Die Klippenregion von Giswyl," with six plates of sections and scenery, gives a full and careful description of one of these remarkable isolated rock masses, which are so frequent on the northern margin of the Alps and Carpathians. Sections representing the actual stratigraphy of the district are followed by others showing how this has been produced; namely, by an overfolding followed by denudation, more especially affecting one of its limbs, and that by a second folding in this portion which has resulted in an overthrust.

Dr. Zschokke's memoir on "Die Tierwelt der Hochgebirgsseen," vol. xxxvii. (1900), pp. 400, with three maps and eight plates, gives much information on the physiography of the lakes of the Higher Alps, as well as a full account of their fauna. Here we find local reproductions of almost Arctic conditions in the midst of a temperate zone, and the fauna, in many respects, may be representative of glacial times. During these the lakes would be mostly, if not wholly, occupied with ice, but as it gave place to water this would be peopled by organisms, partly transferred by birds, partly making their way up stream from lower levels. Of this fauna Dr. Zschokke gives lists and descriptions. It is far from inconsiderable, having representatives of the majority of the invertebrata from the rhizopods upwards, with fishes and amphibians as vertebrates. Of the former, thirteen species are mentioned as occurring in lakes over 1400 m. above sea-level, *Salmo lacustris* and *S. salvelinus* having the highest range, for they occur in the Finailsee, 2690 m. Of amphibians six are enumerated, of which *Rana fusca* reaches the greatest elevation, being found up to 2400 m.

Dr. Zschokke's memoir is full of most valuable information and will be for long consulted by all interested in the distribution of life in the Alps.

Dr. Lorenz's monograph[1] deals with a rather isolated range of no great elevation, the culminating point, the Fläscherspitz, being only 1137 m. above sea-level, but it is one of great interest, which has attracted the attention of Swiss geologists for quite half a century because of its palæontology (the strata range from the Inferior Oolite upwards) and its tectonic structure. On the former ground it is chiefly remarkable, because here the fauna of the "Dogger" changes from its western to its eastern facies; on the latter because its geological structure is extremely complicated, and the relation which it bears to the neighbouring parts of the chain is not easily determined. The range has a general trend from north-west to south-east, the smaller part being in the Principality of Liechtenstein and the rest in Canton Graubunden. A study of the tectonic structure shows the range to consist of Jurassic and Neocomian beds, its south-eastern portion being formed of a much-broken overfold pointing towards the north-west, followed in this direction by a synclinal, which includes a minor overfold and has its axial plane roughly parallel to the former one. Dr. Lorenz connects these crust wrinklings with the famous "Glarner doppel-falte," which, however, he would prefer to call the "Glarner Bogen." The structure, in his opinion, is a result of the sinking (senkung) of the Oberland massif. He gives a succession of sections along the line of curve to prove the relationship, but we should substitute "upheaval" for "sinking" in explaining the structure. The crystalline core indicates the region where the oldest rocks have been raised to the greatest elevation, and have thus produced, by their resistance to further movement, the wrinkling, overfolding and overthrusting of the peripheral sedimentary masses. He thinks also that there have been two sets of movements, which indeed is corroborated by other regions of the Alps.

GEORGE FRANCIS FITZGERALD.

THOSE who knew the University of Dublin twenty years ago will remember that the idol of the undergraduates and the hope of the older men was George Francis FitzGerald. He was of high intellectual lineage on both sides: his father was the most distinguished prelate in the Irish Protestant Church, and his uncles are men of large and original scientific achievement. His early education was conducted at home, in company with his two brothers, one (now professor of engineering at Belfast), a year older than himself, the other younger. He was good at physical science and all subjects requiring close observation, from his earliest years; and the ambition to become a master was soon aroused. The mathematical and physical tendency seems to have come mainly from his mother's side, his strong metaphysical bent from both sides of the family. In his student career he attained all the distinctions that lay in his path with an ease, and wore them with a grace, that endeared him to his rivals and contemporaries. On taking his first degree in 1871 he settled down, at twenty years of age, after the manner of the pick of the Dublin men, to a wide and independent course of reading with a view to a Fellowship. At that time vacancies were of very rare occurrence; so that it was not until 1877, on his second time of trying, that he attained the position of a Fellow of Trinity College. The examination in mathematical and physical science included papers on selected portions of the works of the great mathematical physicists; to a mind of the calibre of FitzGerald's, the early and intimate acquaintance which was thus promoted with the classical writings of Lagrange and Laplace, of Hamilton and MacCullagh, with their modes of thought as well as the results that they won, must have formed the best possible foundation for a scientific career. A training which aims only at sound knowledge and established results may find a shorter path in the study of the latest text-books of the day; but if a man is to be a true leader he must be interested even more in the philosophy than in the facts of his science. It must have been of rare value to a maturing mind of keen temper to observe closely at first hand the lines of attack of the great masters of the past age on problems which were crystallising into knowledge. Acquaintance with the present state of science, however detailed and exact, assumes its full value as an instrument of progress only when it is accompanied by appreciation of the difficulties that had to be circumvented in order to reach it, and by observation of the way in which complete logical precision may have to be attained at the expense of temporary limitation. The subjects that were grouped around physical optics were approached in Dublin, in those days, through the study of MacCullagh's optical memoirs; these writings were based on a remarkable combination of keen analysis of the facts and direct application of the generalised dynamical methods of Lagrange, thus presenting all that interest of nascent scientific discovery which the same topics still retain in their wider connection with the general problem of the æther. Whatever may be the defects of MacCullagh's analysis, it had the saving merit that it put forward no claim to finality; its critical comparison and contrast with those of Cauchy and Neumann and Green, and the difficulties which its procedure suggested from a restricted dynamical point of view, were the very things with which a mathematical analyst might be impatient, but over which a mind constituted like FitzGerald's would eagerly brood. When the great Treatise of Maxwell, which threw a flood of light on these fundamental problems from an altogether novel source, came into hands thus prepared for its appreciation, it is not surprising that a main scientific interest became established for life.

After obtaining his Fellowship, FitzGerald became attached to the department of experimental physics, and conducted or influenced much of the teaching in physical science, in addition to carrying on the work of a College tutor. In the latter capacity he was eminently successful. It was an object of ambition to gain admission to his side, which was always full a long time in advance. He had considerable athletic prowess, which was kept up for many years; and his services were in great request for presiding over and administering the athletic organisations of the College. He gave up tutorial work in 1881 on succeeding to the chair of experimental philosophy, which he held for the rest of his life. He became a Fellow of the Royal Society in 1883, and in 1899 received the award of one of its Royal Medals.

In those early years there were three main centres of development of the new departure in electrical theory which has since revolutionised the whole domain of physical science. Maxwell's own presence as a professor had guided the trend of physical thought at Cambridge predominantly into that direction which it has since largely retained; in Berlin, Helmholtz was devoting his great powers and turning the attention of his pupils to the discussion and elucidation of the subject; while in Dublin its study and investigation became vital under FitzGerald's lead and influence. His chief formal memoir, "On the Electromagnetic Theory of the Reflexion and Refraction of Light," was presented to the Royal Society at the end of the year 1878; it retains a place among the classical writings of modern physics. In the years from 1880 to 1885 he contributed to the

[1] "Monographie der Fläscherberges." By Dr. Th. Lorenz. Beiträge zur Geologischen Karte der Schweiz, Neue Folge, X Lieferung, with geological map, 4 plates of sections, and 13 other illustrations. Pp. 64.

publications of the Royal Dublin Society, of which he was secretary for about ten years, many short condensed papers, on the optical and electric influence of the Earth's motion, on the amount of the electric radiation from an alternating current, on a model illustrating the properties of the æther, all of which went straight without superfluous analysis to the core of the matter on hand, and eminently merit Mr. Heaviside's description (*infra*) as "not large in bulk, but very choice and original." At the present time, after so much progress has been made in the abstruse but fundamental topics with which they deal, these pioneering papers, like Maxwell's Treatise on which they are based, still repay careful study. It is much to be desired that they may soon be republished in more accessible form, along with their author's other scattered writings.

As years passed, the calls on his time became more numerous, in the tender care of his family, in the discharge of public duties, and in response to requests for advice from an ever-widening circle of devoted scientific friends; so that his opportunities for continuous study almost disappeared. But he always managed to keep wonderfully abreast of scientific progress in a very wide range of knowledge, and spent most of his spare time in deeply pondering over its meaning. The scientific public of this country was placed very early in touch with Hertz's magnificent and decisive verification of electrodynamic theory, through the attention commanded by FitzGerald's brilliant exposition in his British Association address of 1888. It was fitting that this should come from him; for, as Lord Kelvin has recalled, he had five years before pointed out to the British Association the possibilities of the very plan of obtaining electric radiation of manageable wavelength which in Hertz's hands has led to success. His own activity became more and more absorbed in the administration of the College laboratory, rendered more arduous by limited funds and distance from other scientific centres, and in the promotion of the practical and technical side of physical science. Yet he still followed very closely the progress of abstract mathematical physics; hardly any one could be named who had thought more deeply, or whose knowledge was more available and many-sided, more entirely free from all prepossession or prejudice. At the meeting of the British Association last September he was, as usual, present, and was of course one of the prominent figures; the writer, speaking from full knowledge, can testify that the proceedings of the physical section were interesting and successful from one cause beyond all others—the assiduity with which he devoted himself to attendance, and the unceasing flow of valuable suggestion and appreciative criticism which he contributed. His stores of knowledge were ripening and maturing in fibre year by year; his memory was unfailing, and each new fact or phenomenon seemed to find its place at once in the setting to which it belonged. Whatever views were presented to him, however much they jarred with his own ideas, were certain to receive patient and careful consideration. There was nobody who did more to encourage younger men and to bring out what was best in them; the time which he was accustomed to devote without stint to the elucidation and improvement of the work of others sadly diminished the opportunities for work more especially his own. His advice and judgment were valued over the whole range of physical science, not less in foreign lands than at home, notwithstanding that he published so little. When a physicist or physical chemist came to a puzzle or paradox, or was in doubt between various plans of procedure, it seems to have come to be almost the natural course to write to FitzGerald. A letter of inquiry or criticism always elicited a prompt reply, entirely devoid of pretension to magisterial authority, but certain to bring out new aspects of the subject and exhibit its connections with other problems. He was constantly acting as referee of scientific papers for the Royal Society and other bodies, and was accustomed to interest himself in them as if they were his own work.

He frequently acceded to requests to serve as examiner on physics in other Universities, notwithstanding the serious drafts on his time and energy that were involved; his connection with the University of London in that capacity has been almost uninterrupted since 1888. He became one of the Commissioners of National Education in Ireland in 1898, and immediately threw himself into the task of reconstituting primary education on more practical lines, undertaking a tour through the United States in the autumn of that year in order to study American methods. Last year he was appointed a member of the Irish Board of Intermediate Education, and much was expected from his assistance in working out the difficult problems that engage their attention. In his own University he was always in the forefront of progress, and often wished to move faster than an ancient institution is usually inclined to allow.

In a private letter, in response to a hurried intimation of FitzGerald's death, Mr. O. Heaviside writes as follows:—"I only saw him twice knowingly, once for two hours, and then again for six hours, after a long interval; yet we had a good deal of correspondence at one time, and I seemed to have quite an affection for him. A mutual understanding had something to do with that. You know that in the pre-Hertzian days he had done a good deal of work, not large in bulk but very choice and original, in relation to the possibilities of Maxwell's theory, then considerably undeveloped and little understood; and his way of looking at things was more like my own than anybody's. Well, he found that I had done a lot of work in the same line, and he was most generous in recognising and emphasising it. Too generous, of course. You remember that review of my 'Electrical Papers' that he wrote? No one knew better than myself how to allow for his temperament and desire to help me. He used to write to me a good deal about electromagnetic problems, and I laid down the law to him like—like myself, in fact. He took it all very pleasantly. But I knew all the while that he had a wider field than myself, and no time to specialise much. He had, undoubtedly, the quickest and most original brain of anybody. That was a great distinction; but it was, I think, a misfortune as regards his scientific fame. He saw too many openings. His brain was too fertile and inventive. I think it would have been better for him if he had been a little stupid—I mean not so quick and versatile, but more plodding. He would have been better appreciated, save by a few."

Prof. W. Ramsay writes on the day following his return from India, when the first news came to him:—

"I understand that it has been thought right for some of FitzGerald's friends to contribute each a short notice of him as a tribute to his memory. The blow is so recent and the feeling of personal loss so acute that this is a difficult task. But to me, as to many others, FitzGerald was the truest of true friends; always interested, always sympathetic, always encouraging, whether the matter discussed was a personal one, or one connected with science or with education. And yet I doubt if it was these qualities alone which made his presence so attractive and so inspiring. I think it was the feeling that one was able to converse on equal terms with a man who was so much above the level of one's self, not merely in intellectual qualities of mind, but in every respect. I know that FitzGerald would have been the last to acknowledge this, for he had no trace of intellectual pride; he never put himself forward, and had no desire for fame; he was content to do his duty. And he took this to be the task of helping others to do theirs. This was happily expressed by the President of the Royal Society in awarding him one of the Royal Medals, when he alluded to the great influence exercised on the progress of science, due to FitzGerald's placing his services

unreservedly at the disposal of every one anxious to carry on physical or chemical research.

"I do not think that FitzGerald ever harboured an angry or uncharitable thought about any one, nor have I ever known any one who, knowing him, did not regard him with the greatest love and respect; for he was known to be absolutely true to himself, and therefore to his fellow men. Although he held strong views on many points and could defend them with vehemence, his argument was never a personal one; and it was obvious that he was actuated solely by a love of truth, and that his only object was to defend what he thought to be right. Moreover, what FitzGerald thought to be right was pretty sure to turn out to be right in the long run. May I suggest as the reason why FitzGerald was so universally beloved, that he was a Christian in the truest sense of the word, and that he followed very closely the footsteps of his Master?"

In a letter from Prof. Tilden to the *Times* of February 27, in which, as Dean of the Faculty of Science of the University of London, he "places on record their high appreciation of his brilliant qualities as a man, as a teacher, as an investigator, as a leader of scientific thought," he goes on to speak on his own behalf of FitzGerald's modesty and extreme unselfishness, of the clarification and enlightenment which many a scientific man has owed to his inspiring conversation, of the "most memorable discourse" which he delivered to the Chemical Society in 1896 as the Helmholtz lecture. The key of deep personal loss is struck in a touching and eloquent tribute communicated to the *Electrician* by Dr. O. Lodge, and in a shorter notice in the *Times* and the *Philosophical Magazine*, coming from one who writes with authority on the industrial applications of science.

Prof. Perry, speaking as President of the Institution of Electrical Engineers, records that "in all engineering questions he had not only the laboratory experimenter's point of view, but also that of the practical engineer. His was a mind that saw the bearing of all scientific knowledge on any practical problem. I have no hesitation in saying that in Prof. FitzGerald our profession has lost one of its greatest, most beneficent forces." In proposing a vote of condolence, Prof. Ayrton spoke to the same effect.

The pride and affection which he inspired in his own College is revealed in a masterly appreciation contributed to the *Athenaeum* by one of his colleagues on the literary side. "His appearance was not unworthy of his fame. More striking he was than handsome; but his ample grey locks and beard, his furrowed brow, his penetrating eyes, reminded one of the bust of some Greek philosopher, which we cannot look upon without that instinctive feeling of respect which intellect and character command among civilised men."

For some years he had been in precarious health. He was subject to recurring attacks of digestive trouble; but the buoyancy with which he threw them off, and the unabated zeal with which he returned to his scientific pursuits in the intervals of health, concealed the real gravity of the situation. News of a sudden crisis was received in London and Cambridge with universal feelings of deep concern. He has now passed (on February 21) from the scene of an active and most beneficent career, in the fiftieth year of his age. His memory will not die. It will be carried on by a school of experimental physics, including the names of Joly and Preston and Trouton and W. E. Wilson, which he was mainly instrumental in creating; while in a wider sphere men such as Heaviside and Lodge and Ramsay and Perry have been proud to testify to their indebtedness and to claim him as their master. His scientific place will be henceforth alongside Rowan Hamilton and MacCullagh and Humphrey Lloyd, and the other famous men who have secured for the Dublin school so prominent a position in the edifice of modern physical science. In the higher domain of heart and conduct the recollection of his qualities will be an abiding treasure to all who knew him.

J. L.

NOTES.

WE learn from the Political Notes in the *Times* that the recent dismissals at Coopers Hill College were discussed on Monday at a meeting held in one of the committee-rooms of the House of Commons. The meeting was convened by Sir W. Anson, Sir Michael Foster, Mr. Milward, and Mr. C. P. Trevelyan; and the attendance included Mr. Haldane, Mr. Emmott, Mr. C. Douglas, Mr. Yoxall, Mr. Palmer, Mr. Spear, Mr. E. Gray, Mr. Lecky, Mr. Cohen, Mr. J. G. Talbot, Mr. Bartley, Mr. Norman and Mr. Howard. Apologies for inability to be present were received from Sir R. Jebb, Sir J. Batty-Tuke, Mr. J. A. Campbell, Sir L. McIver and Mr. Leigh-Bennett. This list, it will be seen, includes not only members of all the British parties, but the representatives of all the Universities. It was decided to request another interview with Lord George Hamilton, in order to press upon him the necessity for an inquiry into the whole circumstances. Failing success in this endeavour the matter will be brought forward in the House at the earliest possible opportunity.

IN the House of Commons on Tuesday, Lord George Hamilton said, in reply to a question by Mr. O'Mara:—Colonel Ottley's suggestions for the rearrangement of the course of study at Coopers Hill are dated June 13, 1900, and the report of the board upon them is dated the 24th of the same month. The visitors who signed the report are, with scarcely an exception, experts of the highest authority upon the technical questions submitted to them, and thay are selected in order that they may advise as experts.—Mr. O'Mara asked whether the conclusions were come to by the committee at a single sitting. Lord G. Hamilton said that the committee had the memoranda some time before them. The report was a long and exhaustive one, but he could not say whether its consideration only occupied one sitting. Mr. O'Mara: "Was not the meeting to consider the report called for the 24th, and did not the committee report the same day?" No reply was given. In answer to a further question by Mr. O'Mara, Lord G. Hamilton said:—Colonel Ottley was informed when he became president that the existing system of instruction was not considered to be satisfactory and required remodelling. Colonel Ottley has an unbroken experience of twenty-five years' service in India in almost every department of civil engineering, and the special knowledge he thus obtained of the training and capacity of the young engineers working under him from Coopers Hill pre-eminently qualified him to advise as to the special technical training required for the Public Works Department in India.—Mr. O'Mara asked whether he was to understand that the code of regulations, which provided that the president should be assisted by the teachers in regulating the course of studies, was not carried out by the present president. Lord G. Hamilton understood that Colonel Ottley had been in frequent communication with the teachers.

A SMALL zoological expedition is just starting for the Malay Peninsula. It consists of Mr. N. Annandale, who was a member of the "Skeat" expedition to the Siamese Malay States in 1899, and Mr. H. C. Robinson, hon. research assistant in the Zoological Department of University College, Liverpool. They intend to settle for a year in the native State of Jalor, near the east coast of Lower Siam, and to explore the neighbourhood of Patani and Biseret. Collections will be made in all branches of natural history, while one of the special objects of the expedition is the study of the pre-Malayan tribes.

of Negrito stock who inhabit the centre of the peninsula. A thorough investigation will also be made of the fauna—both living and extinct—of certain very large limestone caves which are found in the district, and are said to extend for great distances underground. The birds of the district will also be studied, and observations made on mimicry and allied phenomena. The ethnographical work ought to be interesting, since Jalor is on the borderland in which the Siamese and Malay races meet. Mr. Robinson is supplied with dredges and tow-nets for the investigation of the marine fauna, and he proposes, by the method of pumping sea-water through fine silk nets, to make a collection of the surface plankton of the Red Sea and Indian Ocean on the voyage out.

COMMANDER R. F. SCOTT, R.N., in naval charge of the British Antarctic Expedition, has stated to a representative of Reuter's Agency that the preparations for the British Antarctic Expedition are now practically complete. The *Discovery*, the expedition's ship, will be launched on March 23, and, after she has been handed over by the contractors, will come round to London, where her equipment and provisions will be put aboard. The *Discovery* has been built on whaler lines, only with greatly increased strength to withstand ice pressure. She is 171 feet long, and 34½ feet beam, and has 1500 tons displacement. She will have auxiliary steam, and is fitted with engines of the latest type. In her construction the lines of the *Fram*, though carefully studied, have not been adopted, as Nansen's ship would have been ill-adapted for the heavy seas the *Discovery* will have to encounter. The expedition will leave London in July or August, and will proceed to Melbourne, reaching there in November. The actual work of the expedition will then begin. The naval staff, in addition to Commander Scott, consists of Lieut. A. R. Armitage, Lieut. Charles Royds, and two other officers yet to be appointed. The scientific direction will be under Prof. Gregory, of Melbourne University, assisted by Mr. Hodgson (biologist), and Mr. Shackleton (physicist). The medical staff will consist of Dr. Koettlitz and Mr. Wilson.

HIS MAJESTY THE KING has signified to the president and council of the Marine Biological Association his pleasure in becoming the patron of the Association.

A MEETING of the International Association of Academies will be opened at Paris on April 16. Several delegates of the Royal Society will be present.

THE Bessemer gold medal of the Iron and Steel Institute for 1901 has been awarded to Mr. J. E. Stead, of Middlesbrough, in recognition of the value of his researches on iron and steel. The presentation will take place at the annual general meeting on May 8. Owing to the death of the Queen, the annual dinner will not be held. The autumn meeting will be held in Glasgow, simultaneously with the International Engineering Congress on September 3 to 6.

THE Naples Academy of Mathematical and Physical Sciences has awarded the mathematical prize of 1000 lire for 1899 to Dr. G. Torelli, professor at Palermo. The subject fixed was the totality of prime numbers. The theme for the next award is the theory of invariants of the ternary biquadratic considered preferably in relation to the conditions for splitting into lower forms. The essays may be written in Italian, French or Latin, and must be sent in, designated by a motto, before March 31, 1902.

THE success of the banquet recently given to Prof. Marey by the Scientia Club of Paris, has induced a number of his colleagues, friends and students to form themselves into a committee having for its object the presentation to him of a medal in token of their esteem. There are probably others who would like to show their appreciation of Prof. Marey's work by subscribing to the fund being raised for the preparation of the medal to be struck in his honour. Subscriptions should be sent to M. P. Masson, 120, Boulevard Saint-Germain, Paris.

THE Easter cruise to the Isles of Greece, organised by Dr. Lunn and Mr. Perowne for schoolmasters only, is, we understand, already full. As the idea is evidently an attractive one, another cruise to the principal cities of Spain has been arranged for the Easter vacation, under the direction of Mr. E. H. Blakeney, of the Sandwich Grammar School. The party will leave London on the Wednesday morning before Easter, spending Good Friday at Burgos, Easter Day at Madrid, and visiting Cordova and Seville. Those who then wish to return to England can do so, and will get into the direct express at Seville. A party, however, will be formed to visit Granada, returning from Granada to Seville; and a further section will visit Toledo, those who have not time to take in both cities going straight back, after the visit to Granada, from Seville to London. During the cruise Mr. Blakeney will deliver a couple of lectures on (1) "The Moorish Domination in Spain, (2) "Some Cities and Cathedrals of Spain." We should like to see similar cruises organised for men of science, as has already been done in connection with the *Revue générale des Sciences* (see p. 381).

THE fifth triennial International Congress of Physiologists will be held at Turin, September 17 to 23 of this year. The Institute of Physiology of the University, under direction of Prof. Angelo Mosso, will be placed at the disposal of the Congress. The membership of the Congress is open to (1) representatives of physiological and similar purely scientific societies, for example, the Physiological Society, England; the American Physiological Society; Société de Biologie, Paris; Physiologische Gesellschaft, Berlin. (2) Persons proposed by the National Committee of their own country. In connection with the Congress an exhibition of apparatus will be open from September 14 to 23. To it the Marine Biology station at Naples will contribute a collection of marine forms of animal life useful for comparative physiology. In addition to the General Secretaries, for the work of preparation toward the the fifth Congress, Dr. F. S. Lee, secretary of the American Physiological Society, will discharge secretarial duties in the United States. Those desirous of attending the Congress or contributing to the exhibition should communicate with Prof. Sherrington, General Secretary for the English-speaking countries, Thompson Yates Laboratories, the University College, Liverpool.

THE *British Medical Journal* announces that Dr. Gerhard Armauer Hansen, the discoverer of the lepra bacillus, will celebrate his sixtieth birthday on July 29. His friends and admirers, both in and out of the medical profession of Norway, have decided on that occasion to erect a marble bust of him in the Lungegaard Hospital, Bergen, where he discovered the bacillus. A committee of Norwegians has been appointed to solicit subscriptions from Dr. Hansen's friends in the Scandinavian countries, and Prof. Lassar, of Berlin, has undertaken to collect subscriptions for the purpose on the continent.

A CONFERENCE was held at Liverpool on Monday between representatives of the Liverpool and Manchester Chambers of Commerce and the Liverpool School of Tropical Medicine, with reference to the unhealthy conditions of the towns on the West African coast. Mr. A. L. Jones, who presided, said that the West African merchants and shipowners would do well in their own interest, as well as in the interests of humanity, to take advantage of anything that would tend to improve the condi-

tions of life of the people they might send to the tropics to push their commerce. Hitherto Liverpool merchants had had more to do with the development of trade in that part of the world than perhaps any other merchants. That trade promised to be of great magnitude, and no amount of time and money could be devoted to a better purpose than to improve the conditions of life on the West Coast. They in Liverpool had done something by establishing the School of Tropical Medicine, which had inspired the whole world with a sense of its responsibility. Prof. Boyce suggested that the chambers should send out an expedition of experienced medical men and a young engineer to draw up definite schemes for drainage and water supply. Mr. A. Hutton, chairman of the African section of the Manchester Chamber of Commerce, declared that the sanitary condition of some West African coast towns was disgraceful. If they decided that a commission should be sent out they had better send it themselves, and not wait for the Government. Major Ross agreed with the suggestion to send out another commission. Municipal regulations, he said, were absolutely ignored on the coast, and the Government should be urged to take an interest in the matter. It was unanimously decided to ask Mr. Chamberlain to receive a deputation to consult with him on the questions of sewage disposal, water supply, malaria, and dysentery in West Africa.

A REGRETTABLE state of affairs with regard to the preparation of a Lexicon of the native language of New Zealand, is described in an obituary notice of the Rev. W. Colenso, F.R.S., just published in the "Year Book of the Royal Society." We trust that the following plain statement of the position of the work will lead to something being done to ensure its completion. "In 1861 Mr. Colenso entered Parliament as representative of Napier, when he moved and carried a resolution that the time had come for the State to make an organised attempt to rescue the dying language of New Zealand from oblivion. Being at the time unable to undertake such a work himself, he offered to present the Government with his whole collection of materials for it. In 1865 the Government took up the subject, and in 1866 Mr. Colenso, then being more at liberty, was successfully urged, as the one man in New Zealand thoroughly qualified, to take up the work. Seven years was fixed for its completion, the remuneration to be 300*l.* per annum. Before half that period had expired, another Ministry, with other views of the value of a Lexicon, had supervened, by whom its author was informed that, half the time allowed for the completion of the work having expired, one-half of the work itself should have been in the press. On the unreasonableness of this view in the case of a work requiring innumerable cross references being represented, a committee of qualified persons was appointed to examine and report on the progress made. The report was to the effect that the author had advanced further in his work than was due up to the time employed, that thousands of pages had been written from the first word to the last, and that seven years was too short a time for the completion of a work of such magnitude. The report was withheld from Parliament, funds for proceeding with the Lexicon were refused, and the unfinished materials were thrown upon the author's hands, one finger of which was permanently disabled by writer's cramp, due to his labours on the Lexicon. A sample portion was, however, demanded to be laid before the House, and letter A produced, but this was "lost," and not discovered till eighteen years afterwards in a departmental pigeon-hole. It was then printed and distributed by Government, partly at its author's expense, in the year preceding his death. Its appearance, dedicated to his old friend Sir George Grey, has been followed by urgent representations to the Colonial Government that the whole materials, which are bequeathed to the State, should be entrusted to a competent editor for publication."

WE have received from Dr. Hergesell, president of the International Aëronautical Committee, a preliminary account of the results of the ascents on February 7. A manned balloon from Cracow attained a height of 4000 metres and recorded a minimum temperature of $-11°$ F. One of the unmanned balloons from Berlin reached an altitude of 9490 metres and registered a temperature of $-67°$; a manned balloon was also sent up. Two unmanned balloons ascended from Trappes (near Paris); one of them reached 12,700 metres and recorded a temperature of $-67°$. From Strassburg two ascents were made; a paper balloon rose to 8000 metres and a temperature of $-49°$ was registered. Ascents were also made from Vienna and Bath. M. Teisserenc de Bort has promised to send one of his coadjutors to Moscow with the view of organising unmanned balloon ascents from that place.

An interesting description of the Lake Superior mining district is contributed to the *Century Magazine* by Mr. W. Fawcett. The yearly output of ore in the district amounts to twenty million tons, which is more than double the product of any other iron-mining region in the world during any single year in history. None of the mines in the Lake Superior country are more than a hundred miles from the lake, but the hills on the summits of which the deposits are found are, in some cases, more than a quarter of a mile above the level of the lake. Several methods of mining are in vogue in the four ranges of the iron region. On the Mesabi range the ore is taken out by means of steam-shovels. The Mesabi ore is found in great masses on the slopes of hills, and virtually the only task before the miner is to scoop it up and load it into the trucks standing on the siding, which are run into the mine just as trucks are often backed into a stone-quarry. Out of some of these immense holes in the ground more than a million tons of ore are taken every year, and it is all dipped up by steam-shovels. Improved systems of mine haulage are also used. Electric or compressed-air motors draw trains, each composed of about twenty trucks, from the mouth of the shaft to the point underground where the ore is being dug out, and machine-drills, driven by compressed air, have displaced the hammer and drill of the pioneer miner.

AT the Institution of Civil Engineers on Tuesday, February 26, Messrs. W. H. Stanger and B. Blount described the rotatory process of manufacturing cement. By this process it is possible to approach the theoretical ratio of acids to bases, and to obtain a cement which is stronger and sounder than the best cements commercially prepared by discontinuous processes. The largest and most complete installation of rotatory kilns is that at the works of the Atlas Cement Company of Northampton, Pennsylvania. The output of this works is between 8000 and 9000 tons per week, *i.e.* about four times the amount of most large European works, and the whole quantity is obtained from rotatory kilns. The raw materials used by the Atlas Company are a calcareous shale and a limestone. These are crushed, dried, finely powdered and fed mechanically into rotatory kilns. The kilns are steel cylinders 60 feet by 6 feet 6 inches, set on a slight incline and capable of being rotated by suitable gearing. The fuel is powdered coal driven in by a blast of air through an injector burner at the lower end of the kiln. An intensely hot flame, readily controllable, is thus produced, and heats the raw materials introduced at the upper end of the kiln, and caused to travel downwards in a direction opposite to that of the blast. The materials are thus heated systematically, and at the lower end of the kiln near the burner become converted into clinker. This falls into a rotating cylinder lined with firebrick, through which passes a current of air serving to feed the coal-dust flame. A great part of the heat of the clinker is thus regenerated. The clinker is then roughly crushed between rolls which work under

a spray of water and passes through a final rotating cooler into trucks, by which it is conveyed to stock-boxes over the grinding plant. From the crushing of the raw materials to the storing of the finished cement, no hand labour was employed, all conveyance, distribution and transmission being done mechanically.

IN the *Journal* of the Royal Statistical Society, lxiii. part iv., Mr. Thomas Welton discusses the distribution of population in England and Wales and its progress from 1801 to 1891. In 1801 the author finds (1) that urban populations, including most small towns, amounted to 35 per cent. of the total population; (2) that rural districts, exclusive of areas surrounding towns, included 91 per cent. of the total area; (3) that "populous" areas were less than 1 per cent. of the whole; (4) that the density of population averaged 47 per square mile in sparsely peopled districts and 103 per square mile in the better peopled rural districts. In the unprogressive districts, Mr. Welton finds much uniformity (1) in the comparative large increase of population from 1811 to 1821; (2) in the maintenance of a reduced increase from 1821 to 1841; (3) in the prevalence of low rates of increase in unprogressive towns and populous districts from 1851 to 1891; (4) in the absolute decrease of population in rural districts, with certain exceptions, from 1851 to 1891. The general inquiry brings out the vast change in the territorial distribution, the amount and the means of support of our population since 1801, and at the same time the moderate extent of country affected by the developments of this period.

THE whole of Part i. of vol. lxix. of the *Zeitschrift für wissenschaftliche Zoologie* is devoted to an important paper by Herr J. Meisenheimer on the developmental history of the bivalve mollusc *Dreissensia polymorpha*. In addition to figures in the text, the memoir is illustrated by thirteen beautifully executed plates.

WE have received the tenth annual report of the Society for the Protection of Birds. The advance of this body, both in the number of its members and in its financial resources, is reported to be steady, although its efforts might be greatly extended if a larger income were at the disposal of its council. Among the efforts of last year, a special crusade has been made against the pole-trap; and, as a model to other landlords, a paper of instructions has, by permission, been issued to the gamekeepers on the estate of Lord Barnard, forbidding the use of this instrument and the destruction of certain specified birds. The practice of ornamenting poulterers' shops with the carcasses of non-edible birds at Christmas has also been discouraged. The announcement of several clutches of great skua eggs for sale in London last June drew the attention of the Society to the necessity of further protection for the bird in question; and on their initiation a proposed sale at the same time of the eggs of other British birds taken during last season was abandoned. Attention is also directed to the resolution recently passed by the B. O. U., discouraging the collecting of eggs or skins of certain of our rarer birds. The latter part of the report deals with work abroad.

IN the *Ibis* for January, Mr. Chalmers Mitchell, from the study of the anatomy of kingfishers, makes a further important contribution to a right understanding of that peculiar feature in the arrangement of the quills of the wings of certain birds now known as "diastaxy." It will be within the recollection of many of our readers that in 1899 Mr. Pycraft and Mr. Mitchell independently made communications to the Linnean Society in which they showed that the gap which occurs in the diastaxic wing is not due to the loss of a quill, whence they were led to abrogate the original term "aquinto-cubitalism." In his own communication Mr. Mitchell showed that among pigeons both "diastaxy" and "eutaxy" (a regular series of quills) might occur, and also that the latter was the more specialised type. Similar conditions are now shown to obtain among the kingfishers, in which also, as indicated by their myology, eutaxy is the specialised modification. The gradual change from perfect diastaxy to complete eutaxy in this group is most clearly explained by the diagrams illustrating Mr. Mitchell's communication.

ARTICLE 19 of vol. xiii. of the *Bulletin* of the American Museum of Natural History contains a revised memoir on the phylogeny of the European rhinoceroses, by Prof. H. F. Osborn. The author is of opinion that the rhinoceroses (inclusive of the Siberian Elasmotherium) are divisible into six distinct phylogenetic subfamilies, three of which are represented by existing members of the family. Rhinoceros proper, he considers, is now restricted to the Indo-Malay countries, as is Ceratorhinus, as represented by the Sumatran species, the two African species being assigned to a third genus, Atelodus. More importance is attached to the structure of the skull (especially the form of the nasal bones) than to that of the molar teeth, which may have been independently modified for grass-eating in two or more species. Accordingly, Elasmotherium, in place of being considered a specialised type akin to the white rhinoceros of Africa, is affiliated to the middle Tertiary Aceratherium. Again, the great two-horned rhinoceros of the Indian Siwaliks (*R. platyrhinus*) is removed from its association with the aforesaid African species to find a position next to the living Sumatran animal.

THE Council of the Zoological Society has given instructions for the publication of an index-volume to the new generic names mentioned in the "Zoological Record," vols. xvii.–xxxvii. (1880–1900). The volumes previous to vol. xvii. have been indexed in the "Nomenclator Zoologicus" of Scudder, published by the Smithsonian Institution in 1882. The contemplated index-volume of the "Zoological Record," in order to increase its usefulness, will include names omitted from Scudder's list and from the volumes of the "Zoological Record." Thus zoologists may have at their disposal (in the "Nomenclator Zoologicus" and the new index together) a complete list of all the names of genera and subgenera used in zoology up to the end of 1900. It is requested that any one who knows of names omitted from Scudder's "Nomenclator," or from the volumes of the "Zoological Record," will forward a note of them, together, if possible, with a reference as to where they have been noticed or proposed, so that the new list may be made practically complete. Such information should be addressed to the editor of the "Zoological Record," 3 Hanover Square, London, W.; or to Mr. C. O. Waterhouse, British Museum, Natural History, South Kensington, London, who is engaged in compiling the list.

THE *Journal* of the South-Eastern Agricultural College contains an article by the Principal, Mr. A. D. Hall, on the economic aspects of the cultivation of sugar beet in England. The matter is gone into very fully, both from the point of view of utilising the produce as food for farm stock, and of the manufacture of sugar. In a feeding experiment with sheep, where mangels were tried against sugar beet, the advantage rested with the mangels, the writer's verdict being that "The superiority of the mangold is very manifest, and it is clear that it will not pay the farmer to grow sugar beet for feeding purposes." Nor, with foreign bounties on exported sugar, does it appear that there is any prospect of producing sugar at a profit in England. The writer has shown that the price obtained by the German grower cannot be looked for in this country, and concludes that "At the present price of sugar, no factory could afford to pay for sugar-beet a price that would be remunerative to the farmer." The same issue of the *Journal* also contains an article by Mr. Hall on the influence of certain manurial substances on the

quality of barley, the results of his experiments being confirmatory of the best agricultural practice, namely, that though a moderate dressing of soluble phosphate may not have much effect on the yield, it produces a marked improvement on the quality of the grain.

THE *Revue Scientifique* contains an article by Prof. Thoulet on the International Congress of Oceanography held at Stockholm in 1899. A full account is given of the proceedings and conclusions of the Congress, and Prof. Thoulet expresses profound regret at the non-participation of the French Government and at the lack of interest in the subject in France generally. A number of the physical and chemical points dealt with by a section of the Congress are discussed, and certain questions raised, particularly with regard to the specific gravity of sea-water *in situ*, which merit the attention of the Committee appointed by the Congress to report on such matters.

La Géographie contains an account of two scientific expeditions on the east and west coasts of Madagascar, by Mr. E. Colin. The work of these expeditions was chiefly topographical and magnetic. From Andevorante, Vatomandry and Mahanoro the coast turns more to the south-south-east than appears on the maps, and the positions of the two last-named towns lie more to the south. Combining the magnetic observations of 1892, 1896 and 1900 at Tamatave, Ampanotoamaisina, Andevorante, Vatomandry, Marosika, and Mahanaro, it appears that along the zone of the east coast the declination increases and diminishes alternately in the order of the stations named, the maximum occurring at Andevorante and the minimum at Vatomandry; and that the declination and dip vary in opposite directions.

A REPORT on the permo-Carboniferous Coal-measures of Clermont, by Mr. B. Dunstan, has been published by the Geological Survey of Queensland. In the district described there are several tracts of Coal-measures, the largest area exposed being that of Blair Athol. There are also tracts of granite, of slates and schists with auriferous quartz-reefs, and of Devonian and Tertiary strata. It appears that upwards of 65,000 tons of coal have been obtained from the Blair Athol coal-field during the past ten years, and that more than seven million tons of the best Clermont coal are still available. The coal is well adapted for locomotives, and has been mainly used for them. It is remarked that in the Coal-measures there are strata derived from the auriferous slates and schists, and that therefore there might have been streams entering the old Carboniferous lagoon, which brought gold into channels now hidden by more recent accumulations: hence future developments may lead to the discovery of some of these gold-bearing alluvial deposits below the coal-seams.

THE ninth course of public lectures in connection with the Childhood Society, which exists for the scientific study of the mental and physical conditions of children, will be given in the library of the Sanitary Institute on Thursday evenings during this month. The subjects will be, Food dietaries in relation to school-life, by Dr. R. Hutchinson; Examinations in their relation to mental growth, by Prof. H. L. Withers; Experimental psychology, and the study of childhood, by Dr. W. H. R. Rivers; Observations of children after the methods of natural history, by Dr. Francis Warner.

IN view of the widespread opinion that in future many of the fundamental principles of theoretical chemistry will have to find a place in elementary lectures on inorganic and analytical chemistry, we note with interest a series of lecture experiments described by Messrs. Noyes and Blanchard in the *Zeitschrift für physikalische Chemie*, vol. xxxvi. pp. 1–27. The experiments illustrate various phases of the theory of electrolytic dissociation, the laws of equilibrium in solution and the velocity of chemical reaction. They are well chosen, and the necessary details of manipulation are carefully described.

Bulletin No. 89 of the U.S. Department of Agriculture (Office of Experiment Stations) consists of a report of experiments on the effect of muscular work upon the digestibility of food and the metabolism of nitrogen, carried out at the University of Tennessee by Prof. C. E. Wait. Although the effect of muscular work has been considered already in numerous dietary studies, yet up to the present very little information in this special connection has been obtained. As a result of sixteen detailed experiments it is found that, comparing the elimination of nitrogen in the urine during the periods of little muscular activity and normal diet with that during periods of increased activity and a diet furnishing energy largely in excess of the heat equivalent of the measured work performed, there is a slight decrease under the latter condition. This is true even when the possibility of a lag of considerable duration between the breaking down of nitrogenous material within the body and the excretion of nitrogen in the urine is admitted.

AMONG the recent captures made at Plymouth by the Marine Biological Association the most noteworthy are the polychæte *Bispira voluta-cornis*, the crustacea *Galathea strigosa* and *Pirimela denticulata*, the mollusca *Lima hians*, of which many specimens were found in a small patch of muddy stones, making their nests in the crevices between the stones, *Pinna pectinata* and *Scalaria communis*, and the Blenny *Blennius galerita*, of which a small specimen was found between tide-marks. The following animals, among others, are breeding:—Crustacea: *Galathea squamifera*, *Eurynome aspera*, *Pirimela denticulata*, *Gnathia maxillaris*, *Dynamene rubra*. Mollusca: *Lacuna vincta*, *L. pallidula*, *Purpura lapillus*. Pisces: *Cottus bubalis*. An increasing number of larval forms is shown by the tow-net captures, especially of Trochospheres, Veligers, Nauplii and Zoææ. It is to be feared that the octopus (*Octopus vulgaris*) will again be in evidence this summer, as there are already records of its appearance at Plymouth and Mevagissey.

THE additions to the Zoological Society's Gardens during the past week include a Sooty Mangabey (*Cercocebus fuliginosus*) from West Africa, presented by Mr. W. Field; a White-fronted Capuchin (*Cebus albifrons*) from South America, presented by Mr. E. P. Rickcord; a Sykes's Monkey (*Cercopithecus albigularis*) from East Africa, presented by Mr. Geo. Smithers; a Blotched Genet (*Genetta tigrina*) from Africa, presented by Captain R. L. Haddock; a Slender-billed Cockatoo (*Licmetis nasica*) from South Australia, presented by Lady Gertrude Lawford; a Virginian Colin (*Ortyx virginianus*) from North America, presented by Mr. B. N. H. Jones; a White-collared Teetee (*Callithrix torquatus*) from Brazil, a Pig-tailed Monkey (*Macacus nemestrinus*) from the East Indies, a Red-bellied Thrush (*Turdus rubriventris*), a Blue-fronted Amazon (*Chrysotis aestiva*) from South America, a Rose-coloured Pastor (*Pastor roseus*) from India, two Fox Sparrows (*Passerella iliaca*), two Chipping Sparrows (*Spizella socialis*), two Snow Birds (*Junco hyemalis*), two White-throated Song-Sparrows (*Zonotrichia albicollis*) from North America, two Undulated Grass Parrakeets (*Melopsittacus undulatus*) from Australia, a Sclater's Cassowary (*Casuarius philipi*) from New Guinea, three Toco Toucans (*Ramphastos toco*) from Guiana, an Allen's Porphyrio (*Hydrornia alleni*) from West Africa, deposited; two Emus (*Dromaeus novae-hollandiae*) from Australia, purchased; four Chinese Bulbuls (*Pycnonotus sinensis*) from China, received in exchange.

OUR ASTRONOMICAL COLUMN.

VARIABILITY OF EROS.—In the *Astronomische Nachrichten* (Bd. 154, No. 3688), Dr. E. von Oppolzer describes his observation of the planet Eros, which led to his announcement of its variations in brightness. The measures were made with the Zöllner photometer on a Grubb refractor of 8½ inches aperture at Potsdam.

In the same journal there are further confirmatory reports from the observatories of Königsberg and Heidelberg.

NEW TYPE OF SHORTENED TELESCOPE.—In the *Astronomische Nachrichten* (Bd. 154, No. 3691), M. E. Schaer describes some experiments he has made at the observatory of Geneva with the object of facilitating the use of long focus objectives. The light from the object glass is reflected backward and forward from two silvered plane mirrors, so that the distance between eyepiece and objective is only about one-third the focal length. Good photographs of the sun's surface were obtained by using unsilvered glass mirrors and giving an exposure of about one-fiftieth of a second.

CATALOGUE OF NEW VARIABLE STARS.—Harvard College Observatory Circular, No. 54, contains a catalogue of sixty-four new variable stars discovered by the observers at that institution. The majority of these have been detected on examination of the Draper Memorial spectra, by reason of the presence of bright lines of hydrogen in the peculiar cases. For the purposes of this catalogue the variables have been divided into two main classes (1) those having a large range of variation, (2) those in which the extent of variability is small—from half a magnitude to a magnitude. The variables examined are then classified under these headings, 39 of long, and 25 of short period.

NEW COMPONENT OF THE POLAR MOTION.—In the *Astronomical Journal* (vol. xxi. No. 490), Prof. S. C. Chandler makes a preliminary announcement of the detection of a new component relating to the motion of the terrestrial pole. In addition to the already known 428-day and annual terms, he now finds a variation having a period of 436 days and a radius of 0″·09—considerably smaller, therefore, than the others. In the absence of more minute data, the orbit is assumed circular, and the author proceeds to investigate the nature of the variation produced as the resultant of the old 428-day and the new 436-day motions.

The combined motion is found to be subject to a period varying from 431·4 and 415·0 days, the mean length being 428·5 days. The fluctuations are embraced in a cycle of about 57 periods, or 67 years. With respect to the whole cycle, however, the changes of period are of a remarkable character. During five-sixths of the cycle the period remains between its mean value and the upper limit, *i.e.* between 428·5 days and 431·4 days; then it suddenly shortens to minimum, 415 days, and immediately rapidly lengthens again. In addition to this the variations of the radius of motion are also singularly asymmetrical. It is at present about 0″·07 and approaching its minimum value of 0″·05; there was a decrease from 0″·17 to 0″·11 between 1890 and 1897. It will be interesting to note whether the predicted variation of the period actually takes place. Between 1850 and 1890 it persisted at the value 430 days, is now about 428 days, and should continue to shorten to the minimum value of 415 days within the next few years; but of course no sharply-defined numerical limit can be stated on account of the fact that the length of the harmonic cycle, which depends on the difference of the two component periods, is imperfectly determined by existing observations.

INAUGURATION OF A BIRMINGHAM SECTION OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

DURING the last few years, the Institution of Electrical Engineers has actively encouraged the formation of local sections, each having headquarters in some industrial centre. These local sections are free to manage their own affairs, but the parent Institution arranges that important papers read at any of the local centres are incorporated in their journal, as also are local contributions to the discussion of papers read originally in London. Of the five branches now existing, the most recently formed is that in Birmingham.

The Birmingham local section of the Institution of Electrical Engineers has been fortunate in its first chairman, Dr. Oliver Lodge, principal of the new University, who delivered an address from the chair on Wednesday evening, February 27, at the Inaugural Meeting of the section, before a large gathering of engineers. The president of the Institution, Prof. John Perry, was present to support the local movement.

In the course of some opening remarks, Dr. Lodge congratulated the parent Institution on its wisdom and enterprise in forming local branches. Multiplicity of publishing centres was bad for science; but the lack of stimulus to local exertion was bad too. By the present action of the Institution both evils were avoided.

The original Society of Telegraph Engineers dealt chiefly with cable enterprise. Then it took over successively the telephone, electric lighting, transmission of power, and tramcars; and now it seemed about to take over underground traffic, and, in some countries, the railways themselves. Again, a warship was full of electrical contrivances, and the Institution sent a corps of experts to add to the land forces in South Africa.

With regard to the engineer's education, the chairman pointed out that it must be truly scientific. Some said that a general education and mathematics were unpractical and useless encumbrances. What they really meant was that if a youth had these and nothing else he was useless, and that he would be more useful if he failed to possess these, but did possess many other powers and aptitudes. This was true; but the two were not mutually incompatible.

Mathematics, for example, was often so taught that by the time a man had acquired a great deal of it he was somewhat unfitted for anything else. A common-sense mathematical training was an essential for an engineer or for a physicist. Euclid himself was splendid. So was his book for its day and generation, and its purpose as a system of geometrical philosophy admirable; but it had had its day, and for elementary and popular purposes should now cease to be. We were too busy; there was too much to learn nowadays to have time to cross every river by ascending to its source and walking down the other side. Professional guides along the old river path still attempted to hide the bridges, because if they were too easily seen their occupation would be gone; but the bridges were there, and sooner or later even schoolboys would be permitted to make use of them and enjoy the country on the other side, without spending all their days in a toilsome and deterrent mode of getting there over a route approved by the ancients.

The pursuit of pure science for its own sake was a good and wholesome formula up to a certain point, because the tendency of unregenerate man had always been opposed to it. The usefulness of scientific application needed no preaching, but, strangely enough, there was a great tendency to forget or ignore the scientific foundation on which they rested. And the human mind was so constituted that, as a rule, the necessary powers and aptitudes for the two things did not go together. The man who could pursue pure science did so best, as a rule, when he was not distracted by considerations of utility; the applier of science, on the other hand, soon got so immersed in practical details and pecuniary considerations which were clearly vital that he had neither leisure nor inclination, nor always the right kind of ability, for advancing the pure science itself.

Pure science must always advance into territory which appeared for the moment rather useless and barren and aloof from humanity; it must be so, since it was new ground never open to humanity before. Consequently there was a weird unearthliness about it which to people engaged in the turmoil of business might be cold and repellent, if ever they allowed themselves to be assisted to breathe its atmosphere for a moment. The strange, new, unknown, bracing air had a fierce fascination of its own, akin to that of the lone ice-packs of the Arctic seas to the healthy and intrepid explorer, or as the mountain tops were to the members of the Alpine Club. So enticing did the atmosphere of pure science become to those who frequently breathed it that to them sometimes it seemed the only air worth breathing, and the everyday atmosphere of humanity was close and stifling in comparison. Let such men of genius alone; encourage them in their quest; they were not too numerous, and whither they showed the way others hereafter would follow. Moreover, the region which they entered was no limited Arctic circle in reality; it was, as it were, the Arctic entrance to another world, whence, if they penetrated further in pursuit of the pioneers, they would ultimately reach the temperate zones of work and livelihood and applied science; nor

need they doubt but that at some far distant date the human race might at length make its way on through those regions too, and attain, even by that apparently arid path, the rich tropical belt of luxurious verdure and bright sunshine where conflict ceased and art and enjoyment and emotion and religion began. Facts known to few with effort were science, but those same facts when known to all without effort were æsthetic; they could then be appreciated in a fuller and higher way, could be seen in an altogether new light, so that they became fit subjects for poetry, for music, and for art.

Meanwhile, the justification of all pure, dry science lay essentially in its ultimately human bearings. If a subject could be proved to be never capable of any human influence or any relation to humanity, however developed it might become, then its pursuit would be rightly condemned. But such proof could never be given. Again and again had the most unlikely channels developed into fruitful watercourses. We must trust the instinct of our leaders and let them advance unhampered, in the faith that where they felt so much enthusiasm, where they seemed to see their way so clearly and so well, we too, in time, or our descendants, should be able to enter with their aid, and should realise that the remote and at first sight hopelessly inaccessible region was full, after all, of human interest, and of that which contributed to the enrichment of life.

Referring to the present state of electrical knowledge, Dr. Lodge spoke as follows:—

"We are in the beginning of a great era in connection with the pure science of electricity. The almost despised and neglected subject of electrostatics, as known to Franklin, is rearing its head again and pressing to the front.

"The experiment of a charged rod and pith balls is typical of much, perhaps typical of all that goes on in electricity; and how much this means some of us are beginning to guess. It is to the works of Larmor and the late Prof. Fitzgerald that we must look for an explanation of the nature of an electric charge—that blank, that absolute void so wisely left by Clerk Maxwell in his scheme, and by Helmholtz in his—a void occupied only by the isolated brilliant surmise contained in the phrase 'one molecule or atom of electricity.'

"But even before we understand the nature of an electric charge we shall find that the labours of J. J. Thomson have enriched the science of our times with what appears likely to be a unifying and comprehensive generalisation such as philosophers of all time have groped after, for which some of them have strongly hoped."

Concluding his address, Dr. Lodge illustrated with a few simple experiments the most recent views of the nature of the electric current. The atom was ordinarily associated with a charge, and force was required to separate them. This atomic charge, when separated, was known as an electron.

In the electrolyte there was a bodily transfer of atoms with their atomic charges.

In a metallic conductor the charges were handed on as electrons from atom to atom.

But it was in the discharge through highly rarefied gases that the electric current was in its most simple form, for here there was a flow of electrons travelling by themselves, of disembodied charges or electric ghosts. It was interesting to notice that, with their enormous speed of one-tenth of that of light-wave propagation, these electrons were the fastest moving of all known terrestrial objects.

A revolving electron was a magnet. A vibrating one could start light vibrations. And it might even be that inertia itself—that familiar but unexplained property of matter—was but electromagnetic inertia in disguise.

Prof. Perry, in thanking the chairman for his address, remarked that the country was now very much alive to the need for improvement in the scientific education of practical men. All the scientific world was watching to see what Dr. Lodge was going to make of the great problem that was before him of the Birmingham University.

He deprecated the tendency in this Institution to array professors and engineers against one another, and advocated the cultivation of a spirit of mutual helpfulness as between men whose various endowments must be interdependent if they were to be fully utilised.

Prof. Perry congratulated the new local section on its successful start and on its locality, saying that the people of Birmingham were very early in introducing scientific methods of manufacture. The stress of international competition called for the greatest activity in scientific methods in all our centres. The Institution of Electrical Engineers was doing a great work and had a great future before it in binding together the best thinkers in a great association for the common good.

Prof. Threlfall seconded the motion, and the meeting concluded with a feeling reference to the untimely death of Prof. G. F. FitzGerald, who was chairman of the Dublin local section of the Institution.

THE TAMNAU MINERALOGICAL ENDOWMENT.

IN the year 1879 occurred the death of Dr. Friedrich Tamnau, a rich Berlin banker, who was also an enthusiastic collector of minerals; his collection was well known, and was frequently used by mineralogists; a considerable portion of it was given to the Berlin Museum during his life-time, and at his death the remainder was bequeathed to the technische Hochschule at Charlottenburg.

Dr. Tamnau's services to the science of mineralogy did not end with his death. He left to the University of Berlin a sum of 36,000 marks for the purpose of founding a mineralogical travelling fund.

By the statutes of the founder it is enacted that when the fund has accumulated to a sufficient extent it shall be employed in sending away a young and promising mineralogist to some interesting locality, in order to study the modes of occurrence of fine or rare minerals, to collect, and to report upon them. It is expressly stipulated that the fund is to be applied to mineralogical, not geological, purposes. The specimens are to go in the first instance to the Berlin University collection, then to the technische Hochschule, but they may also be given or exchanged to other collections. The administration of the fund is in the hands of three trustees; those named by the founder to hold office at the beginning were Profs. von Rath, of Bonn, Groth, of Strassburg, and Websky, of Berlin.

The first application of the Tamnau fund was made in sending Dr. Tenne, of Berlin, on a successful mineralogical tour in southern Spain.

Two of the original trustees are dead, and the fund is now administered by Profs. Groth, of Munich, Klein, of Berlin, and Bauer, of Marburg.

The second award, 10,000 marks, was made in 1896. Dr. F. Grünling, the well-known assistant of Prof. Groth, first at Strassburg and subsequently at Munich, and now curator of the State collection of minerals in Munich, was commissioned to undertake a mineralogical expedition in Ceylon.

The valuable results of Dr. Grünling's tour have now been published. A triple Heft (Nos. 3-5) of the thirty-third volume of Groth's *Zeitschrift für Krystallographie und Mineralogie* is almost entirely occupied by the scientific work done upon the material which was brought back from Ceylon, and those who wish to see the excellent results of a wise scientific endowment wisely administered cannot do better than glance over this publication.

Dr. Grünling brought back rich collections, especially of the dolomite and the minerals which it contains, of the graphite and of the gem-stones; among the latter the most remarkable are the tourmalines, which constitute a unique series of beautiful crystals.

All these minerals have now been examined by various workers in Prof. Groth's laboratory. The graphite has been the subject of exhaustive study by Dr. Weinschenk, the lecturer on petrology in the University of Munich, who has already published papers on the subject in the *Zeitschrift für Praktische Geologie* and in the *Abhandlungen* of the Bavarian Academy of Sciences. The dolomite has been analysed by Dr. Schiffer, whose results have been given as an inaugural dissertation. And now has appeared this triple Heft of Groth's *Zeitschrift*, containing a general description of Ceylon and its minerals by Dr. Grünling, a research upon the chrysoberyl, the sillimanite and the blue spinel by Dr. Melczer, and a voluminous report upon the tourmaline crystals by Dr. Worobieff, whose memoir occupies nearly 200 pages, and is in reality a crystallographic monograph of the mineral

The fact that so much has been achieved will suggest to the reader that the collection and scientific study of Ceylon minerals has been sadly neglected by our own countrymen. A perusal of Dr. Grünling's paper serves but to strenghten this conviction.

With the exception of an interesting paper on the graphite and rocks of Ceylon, contributed last June to the Geological Society of London by Mr. Coomára-Swámy, but published too late to be alluded to by Dr. Grünling, little has been done. Mr. Coomára-Swámy himself remarks, "No geological survey is in progress in Ceylon; it is much to be hoped that the Government will soon realise the importance of instituting one."

To give a very brief survey of the scientific results:—

Dr. Grünling makes it clear that the graphite always occurs in typical symmetrical veins, though these have been much crushed and altered by earth movements which have spent their energy upon the soft graphite, and have consequently spared the country rock (granulite). Dr. Weinschenk comes to the conclusion that the graphite is of volcanic, and certainly not of organic origin, and is probably due to the action of vapours containing carbon; he suggests that carbon dioxide and cyanogen compounds have played the chief part in its production. Among the associated minerals it is remarkable that, as at Passau, nontronite is one of the invariable decomposition products accompanying the graphite.

Dr. Grünling is of opinion that the gemstones of the sands and gravels were derived from the dolomitic limestone which abounds in some parts of the island, for the spinel, which is certainly found in the limestone, contains sapphire, phlogopite, &c., while the corundum contains phlogopite, rutile and spinel. A granular marble from Wattegama, on the Kandy railroad, proves to be a theoretically pure *dolomite*; it contains, among other minerals, a remarkable blue apatite, which has been analysed by Dr. Schiffer and is found to be a fluor-apatite containing 15 per cent. of chlor-apatite. It is curious that Dr. Grünling was unable to obtain any information concerning the original locality of the tourmalines; they are probably all derived from the cabook or laterite, and from some one place.

Worobieff's crystallographic measurements relate to 110 crystals remarkably rich in faces, and have resulted in the establishment of no less than 131 new forms; one crystal alone presented the faces of fifty-nine forms; the table of calculated angles fills forty-three pages. He finds that the symmetry of tourmaline is undoubtedly ditrigonal, and not tetartohedral as has been supposed by some authors. The paper also contains numerous observations upon the pyro-electric properties of tourmaline, and distinguishes between the faces of the analogous and of the antilogous poles.

Dr. Melczer's paper establishes beyond doubt that the chrysoberyls of Ceylon, of Brazil and of the Urals (Alexandrite) possess the same axes, and that the twinning takes place parallel to (031), not to (011). His optical study of the spinel leads him to the conclusion that the refractive index of this mineral varies with the colour; it is least in the most highly coloured parts.

The whole series of investigations reflects much credit upon the administration of the Tamnau fund, upon those who have collected and studied the minerals, and upon Prof. Groth, in whose laboratory the investigations have been successfully carried out.

The next award of this useful fund will be expected with nterest.

H. A. MIERS.

CRANIOLOGY.[1]

WE have assembled here to-day in order that we may commemorate the merits of John Hunter and such other persons whose labours have contributed to the extension of our knowledge in comparative anatomy, physiology, or surgery. Hunter's life in all its various aspects has been so frequently dwelt on in former orations delivered in this theatre that it is beyond my power to throw any fresh light on this subject. His fame is attributable to his having possessed an intense love of science, indomitable energy, and a self-reliant, manly character. If we turn to his portrait hanging on the walls of this theatre, it would seem that at the time when this likeness was painted Hunter was engaged in the study of the craniology of man and anthropoid apes, for on the table before him there is an open volume, and on its pages we see clearly drawn a human skull and the skull of a chimpanzee. Hunter is portrayed, pen in hand, in deep thought, having just turned away from the book he had been studying, and though his notes on comparative anatomy were unfortunately destroyed with his other manuscripts, we can hardly doubt that craniology was a subject in which he was deeply interested, or it would not have held so prominent a position in this famous picture. It would, therefore, seem that on an occasion such as the present we can do no higher honour to Hunter's memory and to that of some of the able men of science who have followed him than by endeavouring to give in as few words as possible a *résumé* of their labours, with especial reference to the subject of craniology and the light it is capable of throwing on the prehistoric inhabitants of western Europe and of the evolution of the race of men to which we belong. One of the most brilliant and original thinkers who has occupied the presidential chair of this college, Sir William Lawrence, in his ever-memorable lectures on the natural history of man, delivered in this college in the year 1819, from his researches in comparative anatomy, foreshadowed the idea that man and apes were derived from common ancestors. Lawrence's opinions were received with a storm of adverse criticism. Mr. Abernethy, for instance, charged him with "propagating opinions detrimental to society and endeavouring to enforce them for the purpose of loosening those restraints on which the welfare of mankind depend." Time, however, has proved that Lawrence was right, and in the course of lectures delivered in this theatre in February 1899, Prof. Keith, from a careful analysis of the maximum number of anatomical characters common to man and apes, arrived at the conclusion that they are derived from an identical or a kindred stock. While admitting without reserve that man and apes are structurally almost identical, nevertheless, as pointed out by Prof. Huxley in the year 1863, they differ very materially as regards the relative weight of their brains. The carcass of a full-grown gorilla is heavier than that of an average-sized European, but it is doubtful whether a healthy adult European's brain ever weighed less than 32 ounces, or the brain of the heaviest gorilla ever exceeded 20 ounces in weight. Although at the present time there is this marked relative difference between the weight of the brain and the form of the skulls of Europeans and apes, this was not always the case, for the calvaria of the earliest discovered human beings were in form not very far removed from those of contemporary anthropoid apes. This fact leads us to inquire into the nature of the conditions which have led to the increased capacity of the human cranium and to the vast superiority of man's intellectual endowments over those of all the other primates. If we turn to Hunter's preparations in our museum we find among them some remarkable specimens which he describes as "compressed," "unsymmetrical" human crania, which he believed were the result of premature consolidation of one or more of the sutures of the skull. Since Hunter's day various authorities have devoted much time to the subject of the abnormal closure of the cranial sutures in man; prominent among them are the names of the chief of England's craniologists, Dr. Thurnam and Dr. Barnard Davis—the splendid collection of prehistoric and other skulls made by the latter gentleman are now in the possession of our college. From evidence of this nature we have come to learn that the size and form of the skull depends to a large extent on the growth of the bones of which it is formed along the lines of the various cranial sutures.

It is well known that the frontal bone, which forms the vault of the anterior part of the cranium in the young of man and apes, is divided by a suture, and so long as this line of growth, together with the coronal and other sutures by which the frontal is separated from surrounding bones, remains open, the fore part of the skull, and with it the anterior fossæ which it encloses, can expand. But if the frontal and the other anterior sutures of the cranium consolidate early in life the fore part of the skull cannot increase in capacity beyond the size it had reached in infancy. Prof. Deneker, in his work on the embryology and development of anthropoid apes, has shown that in consequence of the early closure of the anterior sutures of the skull of these animals the fore part of their brain does not increase beyond the size it had attained at the end of the first year of life, but in man these sutures do not consolidate until a much later period, so that the anterior lobes of his brain are enabled to, and actually do, become far more perfectly developed than the corresponding lobes among apes; men of the same bulk have four times as much superficial brain surface as anthropoid apes.

Whatever other functions the anterior lobes of the brain perform, their cortical nerve elements, in conjunction with

[1] "The Hunterian Oration." Delivered in the theatre of the Royal College of Surgeons of England on February 14, by Mr. N. C. Macnamara. Abridged from the *Lancet*.

those of the other lobes of the brain, control, to a large extent, our higher intellectual faculties. If we study the collection of preparations of the brains of apes in our museum, it seems to me we shall arrive at a similar conclusion to that expressed by Prof. Edinger, which is, that the gyri of the brain of man and of the anthropoid apes are similar in character, with the marked exception of those convolutions which enter into the formation of the frontal lobes. The superior and the middle gyri of these lobes in anthropoid apes are always much shorter than they are in the brains of average Europeans, and what is of especial importance is, that in the brains of anthropoid apes the inferior frontal gyri only exist in a rudimentary condition of development; this deficiency is very marked with respect to that area of the left inferior gyrus which contains the nerve elements which control our faculty of articulate language. It seems probable that the rudimentary condition of this gyrus in apes is therefore the anatomical expression of the inferiority of these animals to man in intelligence; our intellectual development depending on our possessing the faculty of speech. It may be, anthropoid apes having only rudimentary, if any, specialised nerve centre of speech, that the other parts of their anterior lobes have remained in a comparatively undeveloped condition; whereas the left inferior frontal lobe of man's brain having become highly specialised, and, with it, his power of language, the other convolutions of his anterior lobes, which govern his intellectual faculties, have been stimulated to increased action, and in this way the characteristic expansion of the fore-brain has been evolved among all the more highly civilised races of the human family. But our contention is that the factors which govern the growth of the skull differ from those which develop the brain, and that the imperfect evolution of the frontal lobes among anthropoid apes is to a large extent due to the premature ossification of that part of the skull which encloses the fore-brain. However this may be, the possession of fully-developed anterior lobes of the brain, especially of its left inferior gyrus, is the distinctive character of the central nervous system of all those families of mankind who possess well-developed intellectual capacities. On the other hand, if we compare the skull of an Englishman with that of one of the natives of Australia, we see what a wide difference there is between the development of their frontal regions, and also as to the nature of the sutures of many of their skulls. We shall further discover, from specimens in our museum, that the inhabitants of western Europe in the later tertiary and early quaternary period, as regards the ossification and form, especially of the frontal region of their skulls, more closely resembled that of the chimpanzee than the race of men now inhabiting Europe.

Since Hunter and Lawrence's time, considerable progress has been made in the science of geology and anthropology. Nevertheless, in our search for knowledge concerning the origin and development of prehistoric man in western Europe, we are still hampered by the limited supply of his remains. It could hardly have been otherwise, considering the perishable nature of the human skeleton and the vast length of time, and the great geological changes which have occurred since man appeared in our part of the world. But we have additional evidence concerning the prehistoric inhabitants of this part of Europe, for they have left us some of their imperishable handiwork in the shape of flint and stone implements, which during the past century have been carefully studied in relation to the geological strata in which they were discovered, by Lord Avebury, Prof. Boyd Dawkins, Prof. Prestwich, Sir John Evans, the late Sir William Flower, together with many other English and foreign anthropologists. From the form and workmanship of these stone implements we are now able to classify and assign them to the various periods in which they were manufactured by the early inhabitants of our part of the world.

Up to within recent times it was held that no human beings existed on the earth before the quaternary geological epoch, but in the year 1867 the Abbé Burgeois exhibited a collection of chipped flint weapons which he had discovered in a previously undisturbed tertiary formation; it was not, however, until 1872 that these instruments were admitted to have been made by man or some other animal living previously to the commencement of the quaternary period. Precisely similar flint weapons have since been discovered in tertiary strata in various localities in Europe and in Asia. In the year 1894 Dr. Eugene Dubois found the upper part of a skull (calvaria) in close proximity to a femur and two molar teeth in a well-defined tertiary geological formation in the island of Java. Dr. Dubois was employed by the Dutch Government to examine and report on the fossil-bearing strata of Java, and while engaged on this work he discovered, embedded in a hard mass of tertiary tuffs, the bones above referred to; he brought these fossils to Europe and submitted them for examination to the leading anatomists of this and other countries. They concurred in the opinion that the femur was a human bone belonging to a man of a very low type; "and demonstrating the fact that while rendering its possessor capable of the bipedal mode of locomotion, he still retained some vestiges of adaptation to an arboreal existence." There was a difference of opinion concerning the calvaria, for it was calculated that the capacity of this skull did not exceed 850 cubic centimetres, the capacity of the largest cranium of anthropoid apes being 600 cubic centimetres. Until the Java skull was found, the earliest known human skulls had a cranial capacity of about 1220 cubic centimetres. After an exhaustive analysis of the anatomical characters of the Java calvaria as compared with the skulls of man and apes, Prof. Schwalbe has arrived at the conclusion that the Java skull, taking its capacity and form into consideration, "is on the border-line between that of man and anthropoid apes"; it is more closely allied to the skulls of the Neanderthal group of men than it is to the crania of the higher apes, but it is much nearer in form to the skulls of the chimpanzee than it is to the cranium of the average adult European of the present day. Nevertheless, from a study of the impressions of the convolutions of the brain on the interior of this calvaria it is shown that the inferior frontal convolutions are well marked and approach in form those of man; and although the superficies of this convolution is less than half that of the men of the present day, it is double that of the largest brain of any known anthropoid ape. This fact suggests that the Java man possessed in some slight degree the faculty of speech and that his intellectual capacity was higher than that of any of the anthropoid apes. The post-orbital index or narrowing of the Java skull is 19·3, as compared with the average of living Europeans, which is 12. In this measurement the Java skull comes nearer to the Neanderthal group than to that of anthropoid apes.

In the employing of skulls, which we believe to be the most trustworthy test of human races, we classify them under three heads according to the measurement of their cranial indices. In other words, the measurement of the greatest breadth of the cranium, expressed in percentage of its greatest length, is our guide as to the race to which an individual belongs from a craniological point of view. When the cranial index rises above 80 the head is called "brachycephalic," a broad head; when it falls below 75 the term "dolichocephalic," or long head, is applied to it. Indices between 75 and 80 are characterised as "mesocephalic," intermediate heads.

We have in our museum casts of two crania, and other bones, forming part of human skeletons which were found resting on a ridge of calcareous rock overlooking the river Orneau, in the commune of Spy, Belgium. These remains were unearthed with great care, and there is every reason to believe that they were originally deposited where they were discovered, being covered over with four well-defined beds of débris and clay, in which were found the bones of the rhinoceros and the mammoth, also flint weapons of the Mousterian epoch. One of these skulls has marked palæolithic characters, its brow ridges, like those of the higher apes and the Java skull, are prominent, and the forehead indicates the low type of human being of which this cranium formed a part. Its form, like that of all the other human inhabitants of Europe as yet discovered in the early geological strata of the quaternary (pre-glacial or inter-glacial) period, is of the long type; its sutures are simple and for the chief part are consolidated. We have another cast, presented to our museum by Prof. Huxley, one of our most talented and earnest workers in the science of anthropology, taken from the Neanderthal cranium. This cranium was found, with other portions of a human skeleton in a limestone cave near Dusseldorf. This cave was raised some sixty feet above the existing bed of the river Dussel, and its floor was covered to a depth of five feet by fluviatile deposits, beneath which these human remains were discovered. We have in our collection a skull of the characteristic palæolithic type, presented to the college by one of our former presidents, whose memory is treasured by all who knew him, Prof. George Busk; it was found in a layer of brecciated talus under the north front of the Rock of Gibraltar.

We have also a cast of the calvaria of one of this race found in county Sligo. Another skull of the same type was discovered at Bury St. Edmunds, with the remains of extinct animals and Mousterian flint weapons.

The anterior surface of the lower jaw among the existing races of Europe projects to form the chin. Among apes the reverse is the case, for the anterior surface of their mandibles recede. The Marlarnaud and the Naulette mandibles, of which we have casts, are evidently those of human beings; they were found in geological formations (which also contained the bones of extinct species of animals and palæolithic flint weapons). These bones are distinctly ape-like in character, having receding anterior surfaces, and also the sockets of all the molars are equal in size. The bones of the legs of these pre-glacial or intra-glacial inhabitants of Europe are of ape-like form, and together with the bones of their arms prove that they were a short, powerful race of beings whose average stature did not exceed five feet. They are known as the Neanderthal group of men.

When the glaciers which had extended over the greater part of Europe moved northward, the reindeer passed away with them from our part of the continent. These animals, which could easily be captured by man, had roamed in vast herds over the surface of the country, and had probably afforded the human inhabitants of that period living in western Europe an ample supply of food. The climate of our part of the world at the termination of the glacial period became such as we now experience. Britain was separated from France by sea, and fine rivers, containing numerous fish, filled the valleys of our land; the red deer, wild horse and various fleet-footed animals abounded in the splendid forests which overspread the country. But these animals and the fish of our lakes and rivers were not easily captured, and the human inhabitants of western Europe were therefore compelled to exert their intellectual capacities to an extent not heretofore necessary in order to supply themselves with food and with the skins of animals for clothing. Man was able to overcome the difficulties he had to face, possessing an innate power by means of which (as already explained) his brain was able to develop and so meet the increased demand made upon it in the struggle for existence. That such was the case we judge from the discovery, in geological formations of the post-glacial period, of the skulls of men having the same physical type as those of the strictly palæolithic epoch of western Europe, but with increased brain capacity. These post-glacial human skulls indicate, in my opinion, a gradual transition in form from the ape-like characters of the previous period to a higher standard and distinctly greater brain capacity in the frontal region; this most important question, however, requires further study. With this improvement in the form of the human skull, the flint, stone, bone and horn instruments made by the post-glacial inhabitants of western Europe become more highly finished, indicating the possession of increasing intellectual power on the part of those who made them.

The Engis skull, of which we have a cast, presented to this college by Sir Charles Lyell, is a well-known example of a human cranium of the early neolithic or post-glacial period. Huxley, in his description of this skull, observes: "It takes us, at least, to the further side of the biological limit which separates the present geological epoch from that which preceded it," that is, from palæolithic times. The Borris and Egisheim skulls probably belong to this period, their characters being similar to those of the Tilbury cranium described by Sir Richard Owen, of which we have casts in our museum. These and various other skulls found in geological formations of the time referred to are all of the same type, and lead us to believe that the inhabitants of Europe consisted, in the early neolithic period, of only one race, the descendants of the human beings who inhabited our part of the world during the previous or early palæolithic epoch. They had long (dolichocephalic) skulls, with slightly projecting supraorbital ridges, well-formed noses, and a fairly-developed frontal region as compared with the far more ancient Java and Neanderthal crania. Their lower jaws and the bones of their legs were less simian in character than those of their remote progenitors; they were a small race of beings. We find no metal weapons or instruments with their remains, and we therefore conclude that they were ignorant of the use either of bronze or of iron, nor do they seem to have possessed domestic animals or to have had any knowledge of agriculture. This race of primitive inhabitants of western Europe are best known as the Iberians, and we may conveniently employ this term so long as it is understood to designate the Africo-European stock who were, so far as we know, the only human inhabitants of Europe in the later palæolithic times. It should be clearly understood that no *bonâ-fide* human remains belonging to the early palæolithic period have hitherto been discovered in western Europe which were not of the same type as those above described.

As we pass from the early to the mid-neolithic epoch, we come upon the remains of a race of men who, as regards their physical character and state of civilisation, essentially differ from the people above referred to. The stone implements found with their skeletons are beautifully formed, many of them being highly polished and having sharp cutting edges. A few of the purest bronze axe-heads have been discovered with these remains, and also the bones of domestic animals belonging to species indigenous to Asia but foreign to the palæolithic fauna of Europe. Lastly, we have evidence that these people were acquainted with agriculture and with the manufacture of sun-dried pottery. They paid great respect to their dead chiefs, burying their bodies in natural caves or in tombs formed of huge flag-stones placed edgeways side by side with similar stones laid on the upright ones to form the roof of the building. These structures, the well-known long dolmens, have been found, built on precisely the same plan, in Ireland, England, the greater part of Europe, the west of Asia, India, Arabia and northern Africa. They were not only sepulchres for the dead, but many of them also contained an altar, a place of mourning and of offering, where intercession was made to the spirits of departed chiefs by their relations and tribesmen. The Rodmarton long dolmen or temple tomb (near Cirencester) affords us a good example of one of these structures; it is 180 feet in length and 70 feet broad. We have in our museum a fine human skull which was found in this dolmen, with some well-polished stone implements. If we compare the skull with that of palæolithic man or with the skulls of the early neolithic human inhabitants of western Europe, we are immediately struck by the marked difference that exists between them and the Rodmarton skull. Dr. Thurman's unique collection of crania may be seen in the Anatomical Museum, Cambridge; these crania, for the most part, were unearthed by himself from various English long dolmens and barrows, and they resemble in form, although they are of a higher type than, the skulls found in the caves of Cro-Magnon and Mentone; they are identical in character with skulls found in the long dolmens of France and other countries of Europe. The cranial index, capacity, and other features of the bones of these skulls lead us to assign them all to one and the same race, of which the Cro-Magnon are probably some of the very earliest specimens as yet discovered in western Europe. The three Cro-Magnon and three Mentone skeletons were those of people some six feet four inches and upwards in stature, so that a race of giants in far distant times was no myth. Their cranial capacity was above that of average Europeans of the present day. From their physical conformation and from the remains of the animals found buried with them, which are of Asiatic species, and from other evidence, we are led to the conclusion that the Cro-Magnon race represents the advance guard of the proto-Aryan human family, of which the Rodmarton and many other long dolmen skulls show a more advanced type. These people in far distant ages migrated from the east into western Europe, and from thence spread into our islands; southwards they passed into India, Persia and Arabia, Asia Minor and northern Africa. Over this vast area and far away in eastern Asia we find their remains, with flint and stone implements of the early neolithic type, buried in long dolmens or barrows. The roots of many of the words used by this ancient people exist in most of the languages now spoken in Europe, and their religious sentiments, myths, and, above all, their racial, mental and physical characters, as portrayed in the Rig-Veda and on the ancient monuments of Egypt, are pronounced features in the existing Teutonic and Anglo-Saxon people. From the form of the crania found in many of these long dolmens we know that this tall, fair, handsome, long-skulled race intermarried with the pre-existing short dark Iberian inhabitants of Europe. The fair tall race probably did not at any time, unless in the north of Europe, form a large proportion of the population; they were a dominating, fighting and priestly caste who compelled the primitive small, dark (Iberian) inhabitants of western Europe to work as their slaves.

During the neolithic era, while the descendants of the proto-Aryan stock were slowly feeling their way from the

East along the valley of the Danube into Europe, a very different race was passing from northern Asia into the Baltic provinces. These people formed settlements on the islands of Denmark and westward as far as the north of Ireland. They were the first of the broad-skulled races of the human family who had entered Europe. Their skulls were brachycephalic in form with broad faces and noses, the latter being deeply concave at the base. Their remains are found in the islands of Denmark, especially that of Möen, also in Yorkshire and county Antrim, in which localities their descendants may still be recognised by their physical characters. These people belonged to the stone age of Europe, and by comparing their skulls with those of the Rodmarton or Cro-Magnon crania we see the great difference in form of the prehistoric long and the broad-headed races of men. Until the close of the neolithic epoch there were, therefore, three pure races who formed the sole human inhabitants of Europe, with the exception of those who were the outcome of the intermarriage of the people of these three races with one another.

Passing from the neolithic to the succeeding bronze age, we find that Europe, including our islands, was overrun by a small, olive-coloured, broad-skulled people having characteristic Mongolian features. These were the lake-dwellers of Switzerland and other parts of Europe. They were traders in bronze, and probably, as Prof. G. Mortillet and other authorities hold, they gradually replaced stone, horn and bone with bronze instruments and weapons, effecting in this way a great revolution in the social and industrial habits of the pre-existing inhabitants of western Europe. In these far distant times deep mining operations were out of the question. Superficial copper ores were abundant in most parts of Europe and Asia, but alluvial tin was extremely scarce on our continent, and it is still only found in large quantities in south-eastern Asia. Cornwall, the Scilly islands, the south of Ireland, and some few other places also contained superficial ores of tin. It seems probable that the Mongolians inhabiting the highlands of south-eastern Tibet long before the commencement of the bronze age in Europe spread into Burma, the Malay Peninsula and Cochin China, and there acquired the art of mixing copper and tin in such proportions as to form bronze, the weapons and instruments which they manufactured of this metal being a ready and profitable source of barter in Europe. Together with the broad skulls and other remains of these people we find in the débris of the lake dwellings numerous ornaments made of jade, nephrite and chloromelanite, minerals found in large quantities in south-eastern Asia but not in Europe; and, lastly, vases on which are depicted people in oriental costume and instruments used only by the south-eastern Tibetans have been discovered in connection with the remains of the lake-dwellers and the round or oval burrows of Europe. These people, as a rule, cremated the bodies of their dead, and numerous cinerary urns containing their remains are found scattered over the Wiltshire and other ranges of hills in the south of England. Some of their skeletons, however, have been discovered in the round barrows which are so numerous in many parts of England, Ireland and throughout Europe and Asia. With these remains bronze instruments have been found, indicating, like the stone implements of palæolithic man, various stages of excellency in workmanship. One of the finest skulls in our museum was taken from a round barrow at Codford, Wilts. The form of this brachycephalic skull, together with its nasal bones and orbits, are characteristic of the southern Mongolian race, well known to us as the Gurkhas and Burmese of our Indian empire; a lazy, bright, rollicking, fighting people, intensely superstitious and home-loving—"the Irish of the East" as they have been aptly called. In the course of many centuries the Mongolian people of western Europe have become absorbed into the pre-existing Ibero-Aryan population and a cross-breed has resulted, and from this stock the ancient British people of our islands were derived. Their skulls are mesocephalic (a combination of the long and broad skull) and are amply represented in our museum, the cephalic indices being about 78. Subsequently to the bronze age the ancient Britons were well-nigh exterminated in England by Teutonic races who invaded our country from the north of Europe, the Anglo-Saxons taking the place of the pre-existing ancient British population of England and Scotland. Nevertheless, in some districts of England, such as North Bedfordshire, a number of the descendants of the ancient British stock continue to flourish up to the present day, as also in the greater part of South Wales, much of Cornwall, and the south and west of Ireland, the upper classes in Ireland being clearly derived from the ancient Aryan stock who passed from Gallia into that country during the neolithic period.

We possess the measurements of the heads of some 25,000,000 of the present inhabitants of Europe and the United States of America. From these measurements we learn that a large proportion of the people now dwelling in the countries bordering on the Mediterranean Sea are a short, brunette, long-skulled race, descended, we believe, from those who, from the form of their skulls and other physical characters, occupied that part of Europe and the north of Africa in far distant ages—the Iberian race. Scandinavia and North Germany are inhabited by a tall, fair, long-skulled people, derived from the proto-Aryan races who settled in that part of our continent in the neolithic epoch. A vast triangle, having its base in eastern Russia and its apex on the Atlantic in south-western France, is inhabited by a broad-skulled people derived from Mongoloid or Turanian ancestors. We do not for a moment affirm that these races, as such, have remained pure, far from it, but the results of the measurements of the heads of a great number of the existing inhabitants of Europe point to the conclusions above indicated; and this idea is confirmed by the indices of the splendid collection of crania which occupy so large a space in the museum of this college—a collection which was commenced by John Hunter and upon which a great amount of time and labour has been spent in describing and classifying the skulls which it contains; a work which, in my opinion, should be completed up to the end of the past century.

The characteristic physical type of palæolithic man may be still recognised among the inhabitants of western Europe, although their skulls have grown more capacious, especially in the frontal region. This change in the form of the cranium marks a corresponding advance in the capacity and organisation of the brain, and consequently of the intellectual ability of man: it is, in truth, evidence of his inherent power to overcome the demand made on his mental capacity in order to cope successfully with his ever-increasing struggle for existence, consequent on the growth in number of his fellow-creatures and the more complicated social conditions of his surroundings. Doubtless the form of skull of a large proportion of the inhabitants of our island indicates a cross-breed formed by the intermarriage of the long and broad-skulled families of man who in distant ages met and intermarried in western Europe, thereby improving the stock of their descendants. Races of men, such as the natives of Australia, who have remained in an unchanged environment and without intermarriage with other people, have made but little progress in their intellectual capacity, the form of their skulls continuing of the same type as those possessed by the palæolithic inhabitants of Europe.

The same causes to which we have referred, acting for long periods of time on people of the same race, have led, not only to the hereditary transmission of their physical characters, such as those existing respectively among the northern, central and southern inhabitants of Europe, but have also developed specialised areas of nerve structure in their brains, by means of which they have come to think, feel and reason alike. In this way we are able to comprehend the source and the meaning of large bodies of men belonging to the same race being frequently moved to take common action on matters affecting the well-being of their race; they possess, in fact, like innate sentiments although separated from one another by great distances and living under diverse climates and environment. Their emotions and ideals harmonise because their progenitors existed for many ages under similar external conditions and consequently developed like specialised nerve-centres, which have been transmitted, together with their physical characters, to their successors and become crystallised in their laws and reflected in their conceptions of religion as well as in their social institutions.

In illustration of our meaning we may refer to those revolting pages of history during which Belgium and the Netherlands passed under the dominion of Spain; the Iberian dominating for the time being over a thoroughly Teutonic race. Or we may contrast the existing condition of the Iberian population of South America with the Teutonic Anglo-Saxon inhabitants of the United States, or between the latter and the negro population of America, a subject which is more fully elucidated in my book "On the Origin and Character of the British People."

We have a chart here which shows the result of the recent general election held in this country; the question at issue was one in which the whole of the people in Great Britain were deeply interested. It is remarkable what a large proportion of

the inhabitants of England and of Scotland, mainly of Anglo-Saxon origin, voted together on this subject; whereas a contrary opinion regarding this same question was held by the greater proportion of the people of Ireland, and to a large extent by the Welsh, most of whom are derived from Ibero-Mongolian ancestors. It is difficult to account for the diversity in the sentiments of the people above referred to unless we consider it due to their racial mental qualities. Environment has doubtless played an important part in the evolution of these people, but their inherited racial character has had more to do with the position which the Anglo-Saxon race has gained in the world than the mineral wealth, climate, or protection afforded us by our seagirt coast.

The environment under which even a few generations of men exist would seem capable of influencing the structure of their central nervous system, as illustrated by comparing the mental qualities of our rural and urban population. The conditions under which the city-bred person, child and man, lives engender in the course of a few generations an unstable state of nerve structure, resulting in an excitable character which, if carried beyond a certain point, leads to unsoundness of mind, and may account for the increasing number of lunatics in this and the other large cities of Europe. General Sir Redvers Buller, again, in speaking of the soldiers under his command in South Africa, refers to the fact that our city-born men have imperfect sight compared with men reared in the open plains of the Transvaal, thus affording us another example of the effects of environment on the race. These are a few of the many interesting and important subjects which arise in connection with the study of anthropology, including craniology; and the contents of our museum and library offer unrivalled opportunities to the student seeking for knowledge in those branches of science.

In conclusion, as already stated, much of Hunter's reputation was founded on the result of his labours in those branches of science which tend to elucidate man's nature; and during the past century a succession of English surgeons has carried on the work commenced by our great master, enriching our museum and endeavouring to make this college, not only an examining and licensing body, but, what it certainly should be, an imperial institution for the cultivation and diffusion of those departments of knowledge which bear on the art and science of surgery. The ideas entertained by John Hunter's immediate successors on this subject were ably stated by Sir William Lawrence in his lectures already referred to. He observes that "our own individual credit, and the dignity, honour and reputation of our body, which we are bound to maintain, demand that surgeons should not be behind any other class in the possession either of the cultivation of branches of knowledge directly connected with surgery or in any of the collateral pursuits less immediately attached to it. It is only in reference to such views and objects that the Hunterian collection could have been accepted or can be of any use to this college." Hunter would, if he had still been with us, have thrown all his indomitable energies into the successful working of such an institution, and amidst the turmoil, strife and competition going on around him would, as we see him in this picture, have been engaged in the earnest, accurate, patient study of nature. It remains for our younger members to emulate the example set them by John Hunter, and by such service to secure for themselves lasting satisfaction, and beyond that add to the real dignity and utility of their college and their profession.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—The 222nd meeting of the Junior Scientific Club was held on Friday, February 22. Mr. H. B. Hartley (Balliol) read a paper entitled, "Polymorphism; an Historical and Experimental Account," which was followed by a paper by Prof. Townsend entitled, "The Conductivity of Gases."

CAMBRIDGE.—The subject for the Adams prize in 1903 is, "The bearing on mathematical physics of recent progress in the theory of the representation of discontinuous quantity by series, with special consideration of the logical limitations of the processes involved." The prize is open to all graduates of the University, and is of the value of 225*l.* Essays are to be sent privately to the Vice-Chancellor by December 16, 1902.

The tender for the new School of Botany, to be erected behind the Sedgwick Museum, amounts to some 23,000*l.* It is recommended for acceptance by the syndicate.

AN animated debate occurred in the House of Commons on Tuesday on the attitude taken up by the Board of Education towards higher-grade elementary schools in which science is taught, leading to the judgment in the case of "Regina *v.* Cockerton," that grants made by School Boards for scientific instruction are illegal. In the course of his reply to various criticisms, Sir John Gorst said that the Government proposed to introduce a Bill for the creation of secondary education authorities having power to provide instruction in subjects that were not contained in the Elementary Day School and Evening Continuation School Code. He agreed that we should not have a proper system of education until one authority was established in a district, having control over schools of every kind and every grade. If a change of that kind were made, overlapping would cease and the existing chaos would disappear.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, February 7.—"The Boiling Point of Liquid Hydrogen, determined by Hydrogen and Helium Gas Thermometers." By James Dewar, M.A., LL.D., F.R.S., Professor of Chemistry at the Royal Institution, and Jacksonian Professor, University of Cambridge.

In a former paper it was shown that a platinum-resistance thermometer gave for the boiling point of hydrogen $-238^\circ{\cdot}4$ C., or $34^\circ{\cdot}6$ absolute. As this value depended on an empirical law correlating temperature and resistance which might break down at such an exceptional temperature, and was in any case deduced by a large extrapolation, it became necessary to have recourse to the gas thermometer. The gases used as thermometric substances were hydrogen, oxygen, helium and carbonic acid.

Taking the average values given by the experiments as being the most probable, then the boiling point of oxygen is $-182^\circ{\cdot}5$ and that of hydrogen is $252^\circ{\cdot}5$, or $20^\circ{\cdot}5$ absolute. The temperature found for the boiling point of oxygen agrees with the mean results of Wróblewski, Olszewski and others. If the boiling point of oxygen is raised to -182°, which is the highest value it can have; then an equal addition to the hydrogen value must follow, making it then -252° or 21° absolute. In a future communication the temperature of solid hydrogen will be discussed.

February 14.—"On the influence of Ozone on the Vitality of some Pathogenic and other Bacteria." By Dr. Arthur Ransome, F.R.S., and Alexander G. R. Foulerton.

The experiments have shown that ozone in the dry state, and in such strength as the authors used it, has no appreciable action on the vitality of the various bacteria experimented with, and, so far, the results are in accordance with those of Sonntag and Ohlmüller. Nor did a prolonged exposure to the action of ozone diminish in any way the pathogenic virulence of *B. tuberculosis* in sputum. Single experiments would also tend to show that ozone can have little, if any, effect on the pathogenic virulence of *B. mallei* and *B. anthracis.*

On the other hand, the experiments would appear to confirm the conclusion arrived at by Ohlmüller as to the bactericidal property of ozone when passed through a fluid medium containing bacteria in suspension.

A comparison of the inactivity of ozone as a disinfectant in the dry state with its action in the presence of water suggests a superficial resemblance with other gases, such as chlorine and sulphur dioxide. In the absence of further experiment, however, it would not be possible to press the analogy too closely.

In the dry state, and under the conditions in which it occurs in nature, ozone, then, is not capable of any injurious action on bacteria so far as can be judged from the experiments; and it is concluded that any purifying action which ozone may have in the economy of nature is due to the direct chemical oxidation of putrescible organic matter, and that it does not in any way hinder the action of bacteria, which latter are, indeed, in their own way, working towards the same end as the ozone itself in resolving dead organic matter to simpler non-putrescible substances.

"On the Functions of the Bile as a Solvent." By Benjamin Moore and William H. Parker. Communicated by Prof. E. A. Schäfer, F.R.S.

In this paper evidence is brought forward that the bile exercise

an important action as a solvent, and the authors claim that this is the chief, if not the only function of that secretion. It is pointed out that the bile in this respect has a twofold action: first, in aiding in the excretion of cholestearin and lecithin; and, secondly, in aiding in the absorption of fatty acids and sodium soaps from the intestine. All these substances possess a low solubility in water, and have their solubility increased in bile chiefly by virtue of the properties of the bile salts. The fact that cholestearin is still but slightly soluble in bile explains the well-known fact that gallstones are composed almost exclusively of that substance, while lecithin is very soluble in bile and hence is never deposited. This view as to the action of the bile also furnishes an easy explanation for the so-called "circulation of the bile." It further explains the faulty absorption of fat in the absence of either bile or pancreatic juice, and the almost complete failure of fat absorption when both these secretions are excluded from the alimentary canal.

"On the Application of the Kinetic Theory of Gases to the Electric, Magnetic, and Optical Properties of Diatomic Gases." By George W. Walker, B.A., A.R.C.Sc., Fellow of Trinity College, Cambridge, Sir Isaac Newton Research Student. Communicated by Prof. Rücker, Sec. R.S.

Zoological Society, February 19.—Dr. Henry Woodward, F.R.S., vice-president, in the chair.—Dr. W. G. Ridewood exhibited some microscopic preparations of the hairs of three species of zebra, viz. *Equus burchelli*, *E. zebra* and the newly described *E. johnstoni*, in order to show that the hairs of the last-named animal agreed in structure with those of the other two zebras. A letter received from Prof. Ewart on the same subject stated that he was quite of the same opinion.—Mr. F. E. Beddard, F.R.S., exhibited and made remarks upon a specimen of a female Schmidt's monkey (*Cercopithecus schmidti*) with four mammæ.—Mr. R. Lydekker, F.R.S., described, under the provisional name *Sotalia borneensis*, an apparently new species of estuarine dolphin from Borneo, a specimen of which had recently been received at the British Museum.—Mr. Lydekker also gave a description of the Kashmir ibex (*Capra sibirica sacin*), and pointed out the differences between this and the three other races of *Capra sibirica*.—Mr. F. E. Beddard, F.R.S., read a paper on the broad-nosed lemur (*Hapalemur simus*), which dealt with the points of difference in structure between this species and *H. griseus*.—A communication from Dr. J. G. de Man contained a description of *Potamon* (*Potamonautes*) *floweri*, a new species of crab obtained by Captain S. S. Flower on the Bahr-el-Gebel, during his expedition up the White Nile in 1900, and remarks on other species of Potamon.—Mr. R. H. Burne read a paper entitled "A Contribution to the Myology and Visceral Anatomy of the Fairy Armadillo (*Chlamydophorus truncatus*)," in which the myology of this rare Edentate was reviewed, with special reference to the two previous descriptions by Hyrtl and Macalister, and features were pointed out in which this individual showed a greater similarity to *Dasypus* than those hitherto examined.—Dr. C. I. Forsyth Major read a paper on some characters of the skull in lemurs and monkeys, in which he pointed out, amongst other results, that the *os planum* of the ethmoid, about which some doubts had existed as to its presence in lemurs, was found to occur in the young stages of many of these animals, and that the facial expansion of the lachrymal bone in the lemurs as well as in the monkeys was not a primitive condition but an extreme specialisation.—Mr. Martin Jacoby read a paper containing descriptions of fourteen new species of phytophagous coleoptera of the family Chlamydæ.

Royal Meteorological Society, February 20.—Mr. W. H. Dines, president, in the chair.—Mr. E. Mawley presented his report on the phenological observations for 1900. During the greater part of the winter and spring the weather proved cold and sunless, but in the summer and autumn the temperature was, as a rule, high and there was an unusually good record of bright sunshine. As affecting vegetation the two most noteworthy features of the phenological year ending November, 1900, were the cold, dry and gloomy character of the spring months and the great heat and drought in July. Throughout the whole of the flowering season wild plants came into blossom much behind their average dates, indeed later than in any year since 1891. Such spring emigrants as the swallow, cuckoo and nightingale were also later than usual in visiting these shores. Taking the British Isles as a whole, the crops of wheat, barley and oats were all more or less under average. The yield of hay was poor in the southern half of England, but elsewhere varied from a fair to an abundant crop. Turnips and swedes were almost everywhere deficient, but there was a heavy crop of mangolds. Potatoes were under average. This was a bountiful year as regards fruit, the yield of apples, plums and all the small fruits being in excess of the average.—Mr. A. E. Watson read a paper entitled "A review of past severe winters in England with deductions therefrom." From an examination of the records of the severe winters of the last 300 years, he has come to the conclusion that they are most frequent in the years with the numbers 0–1 and 4–5. He is also of opinion that the severe winter in the middle of each decade is generally a late one (January to March) while that at the beginning or end of each decade is generally an early one (November to January).

MANCHESTER.

Literary and Philosophical Society, February 19.—Prof. Horace Lamb, F.R.S., president, in the chair.—Mr. Charles Bailey made a communication entitled "On *Ranunculus Bachii*, Wirtgen, as a form of *Ranunculus fluitans*, Lamarck." This aquatic plant is very polymorphic, as seen in the series of British examples exhibited. In the south of England, the stout stems are several feet in length, the leaves and peduncles are from six inches to a foot long, and the flowers are as large as a shilling or a florin. It is a frequent plant in the Herefordshire Wye and in the Severn, but in the immediate neighbourhood of Manchester it has been gathered in but one station, viz., the Derbyshire Derwent, at Whatstandwell. The plant occurs in canals and swift-running brooks, but its most congenial station is a well-filled river. It becomes less frequent in Great Britain as one ascends northwards, and just manages to occupy a few of the southern counties of Scotland. The range of examples exhibited showed that there exist all intermediates between the diminutive form collected at Ayton in the north, and the nine or ten feet plant of the New Forest in the south. Mr. Bailey's conclusions regarding this plant accord with Wirtgen's later view of it, namely, that the differences between it and the type are merely comparative.—Mr. R. S. Hutton exhibited an almost exact reproduction of Moissan's electric furnace, which has been set up at the Owens College. There it is possible, with a 50 horse-power engine, to produce a current of 700 amperes at 50 volts, and by that means it is anticipated that researches at the high temperatures thus available—viz., 3500° C., or higher—will shortly be able to be carried out. Graphite prepared in electric furnaces was also shown, as well as specimens of various carbides, carborundum, &c., from the Niagara works. The specimens exhibited illustrated the facility with which some of the rarer metals now become available, those shown being chromium and manganese. A modern form of the Lippmann electrometer was also exhibited by Mr. Hutton.

PARIS.

Academy of Sciences, February 25.—M. Fouqué in the chair.—The appearance of a new star in the constellation of Perseus, by M. Loewy. This star, when discovered by Dr. Anderson, at Edinburgh, on February 21, was of the magnitude of 2·7. Two nights later it was estimated by M. Robert, at Saint-Jean-d'Angély, as being of the first magnitude.—Studies on the agricultural value of land in Madagascar, by MM. A. Müntz and E. Rousseaux. The soil of the belt on the coast line from its composition would probably prove fertile, but the ferruginous earths of the central *massif* are poor and unfit for culture, except at the bottoms of the valleys. The island, taken as a whole, is poorly provided with the materials necessary for plant growth, and it does not appear likely that it could ever support a dense population.—On the appearance of a new star in the constellation of Perseus, by M. Flammarion. A letter to the Permanent Secretary containing the results of observations on the new star, by MM. Lucien Bosc, A. Robert, Lotte, and Bruguière.—On the variations in magnitude and position of the satellites of Jupiter, revealing the existence of a cosmic atmosphere, by Dom Lamey. The observations recorded by the author can only be satisfactorily explained by the assumption of the existence of an atmosphere in the form of a ring, composed of a material too subtle to condense, but sufficiently dense to modify by refraction the images of stars traversing it in the equatorial plane.—On a certain category of transcendental functions, by M. Edmund Maillet.—The superficial traces left by the tools in the operation

of sawing metals, by M. Vasseur. From the analysis given, it would appear that the lines discovered by M. Fremont have no relation with the curves of distribution of deformations in metals, but depend upon the nature and condition of the saw employed.—On the insulating properties of snow, by M. Bernard Brunhes.—On certain conditions of reversibility, by M. Albert Colson. The reversibility of the reaction between carbon dioxide and silver oxide is dependent upon the presence of water vapour.—The compressibility of solutions, by M. Guinchant. Up to a pressure of four atmospheres the volume of the dissolved body is independent of the pressure.—Contribution to the study of indium, by MM. C. Chabrie and E. Rengade. On prolonged boiling, cæsium indium alum deposits pure indium oxide. Determinations of the molecular weight of indium acetylacetonate in boiling ethylene bromide are consistent with the trivalency of this element.—On a new crystallised sulphate of molybdenum, by M. Bailhache.—Some new reactions of organo-metallic derivatives, by M. E. E. Blaise. A mode of synthesis of alkyl-ketonic esters.—Action of the organo-metallic derivatives upon alkyl esters, by M. A. Behal. The final product of the action of an excess of magnesium iodoethylate upon an ester, R.CO.OEt, is an ethylenic hydrocarbon, $R.C(CH_3):CH_2$.—Synthesis of tertiary alcohols in the fatty series, by M. Henri Masson.—On the absorption spectra of the indophenols and the colouring matters derived from triphenylmethane, by MM. C. Camichel and P. Bayrac.—On the constitution of glucose, by M. L. J. Simon.—The diastatic actions of colloidal platinum and other metals, by M. G. Bredig. A solution of colloidal platinum shows a remarkable analogy with the enzymes in its catalytic action towards hydrogen peroxide. Both the colloidal metal and the enzyme increase in activity with increasing temperature up to a certain point, and then fall off, and both are similarly influenced by the addition of minute quantities of hydrocyanic acid or sulphuretted hydrogen.—The function of the peritoneal canals, by M. S. Jourdain.—The action of chloroform upon the reducing action of the blood, by MM. M. Lambert and L. Garnier.—On the identity of the modifications of structure produced in vegetable cells by cold, plasmolysis, and by drying, by MM. L. Matruchot and M. Molliard.—Food value and culture of the furze, by M. A. Ch. Girard.—The examination of a meteorite which fell in the island of Ceylon on April 13, 1795, by M. Stanislas Meunier.

DIARY OF SOCIETIES.

THURSDAY, MARCH 7.

ROYAL SOCIETY, at 4.30.—Further Observations of Nova Persei: Sir Norman Lockyer, F.R.S.—Some Physical Properties of Nitric Acid Solutions: V. H. Veley, F.R.S., and J. J. Manley.—The Anatomy of Symmetrical Double Monstrosities in the Trout: Dr. J. F. Gemmill.—Preliminary Communication on the Œstrous Cycle and the Formation of the Corpus luteum in the Sheep: F. H. A. A MANUAL OF MEDICINE.

A Manual of Medicine. Edited by W. H. Allchin, M.D., F.R.C.P., F.R.S. Edin. Vol. i. Pp. viii + 442. Plates 2; and Vol. ii. Pp. viii + 380. Plates 2. (London: Macmillan and Co., Ltd., 1900.) 7*s.* 6*d.* net each.

THE work before us is to consist of five volumes, and will thus eventually cover some 2000 pages; the term manual, therefore, by which it is designated, applies rather to each individual volume than to the whole work. It is essentially a system of medicine. It can be seen at a glance that the book is of an essentially different type from Allbutt's system, recently completed. It deals much more succinctly with the respective subjects, and contains no bibliographies. We assume from this—there is no preface—that the work is intended not so much for a book of reference as a text-book for students, and as a handy reference book for practitioners. In the space at our disposal it is impossible to consider at all fully the two volumes before us, and nothing remains but to take a few of the most important monographs as types.

Vol. i. begins with an introduction by the editor, in which he discusses the bases of our conception of disease and the classification of diseases. He concludes by adopting the orthodox classification, viz. local, or diseases of individual organs, and general, or those diseases in which the entire body is concerned and no preponderance of symptoms in one region occurs. It is with this latter class of diseases that both the volumes before us are concerned. The general diseases are again divided into those of extrinsic and intrinsic origin; the former including abnormal states caused by atmospheric influences, parasites, vegetable and animal, and poisons introduced into the body as such; the latter comprising primary perversions of general nutrition and diseases of the blood.

The infections are treated by Dr. Sims Woodhead. The article includes the bacteriology of the subject, in so far as its essentials are concerned, and bacteriological chemistry, a consideration of toxins, anti-toxins, immunity and, finally, a classification of the infective diseases met with in man, arranged according to their cause. The same author writes upon sapræmia, septicæmia and pyæmia. Dr. Hale White communicates a succinct article upon fever. He discusses the factors at work in the production of fever which differ from the physiological standpoint, and enters at some length into the parts played by increase of heat production and diminution of heat loss. According to him fever cannot, from the standpoint of its physiological cause, be regarded as an entity, the method of its production varying with the cause. The author concludes by indicating the methods which should be employed to reduce fever. Dr. Cayley contributes a full clinical monograph upon typhoid fever. The article is very carefully written, and, considering the space it covers (twenty odd pages), is very complete. It is interesting to note that the author considers "the evidence for the preventive action of the typhoid vaccine much stronger than that for the curative action of the serum," and recommends its trial "during epidemics and in persons, like nurses, who are especially exposed to infection."

Plague and cholera are dealt with by Dr. Cantlie. The author gives the results of Hafkine's inoculations in both these diseases. The articles upon dysentery, leprosy, malaria and several other tropical diseases are also written by Dr. Cantlie. The chapter on diphtheria is by Dr. Foord Caiger, and includes a most instructive table compiled from the total admissions into the Metropolitan Asylums Board hospitals of patients suffering from this disease. The table deals with a total of 25,000 cases, the ages of which vary from one year to sixty, and shows that while the average mortality of the whole is 24·7 per cent., the mortality in children between one and two years old is 50·2 per cent. The satisfactory results of the treatment of diphtheria by anti-toxic serum are evidenced by the dictum of the author "that a dose of from 2000 to 8000 units of anti-toxin should be given at the earliest moment in every case when the patient is a child." The articles on Rötheln, measles, scarlet fever and chicken-pox are from the pen of the same author.

Dr. Monckton Copeman supplies two monographs, upon small-pox and vaccinia respectively. In the article on small-pox reference is made to the work of Mr. Power concerning small-pox hospitals acting as a source of infection through the small-pox contagion being carried from them for a certain distance through the air. The importance of this fact cannot be over-estimated, and it is to be hoped that definite results, quantitative with regard to distance, will be obtained in this regard for other infectious diseases. The article on vaccinia includes extracts from the *Report* of the Royal Commission on Vaccination (1898), and also a consideration of the technique of vaccination.

In vol. ii. general diseases are continued. Dr. T. W. Shaw and Dr. James Cantlie contribute articles upon the diseases caused by parasites. Dr. Poore, conjointly with the editor, writes upon diseases determined by poisons introduced into the body as such—alcohol, morphine, cocaine, phosphorus and the ordinary metallic poisons being dealt with. Dr. Lazarus-Barlow contributes a general article upon inflammation and its sequels, and the editor one upon malignant disease. The possible parasitic origin of malignant growths is discussed shortly but adequately, and the references to the chief of the many exhaustive monographs upon this subject are given, a method, it may be noted in passing, which might have been advantageously adopted more frequently throughout the book. A short but interesting essay upon rickets is contributed by Dr. Coutts. The ætiology of this disease is only very shortly discussed; but it is instructive to note that the author directly contradicts the assertion that rickets never occurs in children fed entirely on mothers' milk. It is of the greatest possible importance to the public health to be quite clear upon this subject; the universality of rickets and the profound extent to which it affects the subsequent growth and activity of the various organs of the body is probably unsurpassed by any other morbific agency. Two articles upon diabetes mellitus and insipidus, respectively, are written by Dr. Bertrand Dawson. The article on gout is by Dr. Luff. In writing a short article presumably for students one

 X

must obviously be didactic. This method, however, has its limits; in this case we think these limits have been somewhat exceeded. The student, or even the practitioner, who does not supplement the knowledge of gout he has obtained from this source by some further reading will not, we are afraid, be in possession of the whole truth concerning this disease.

The remainder of the book is devoted to the diseases of the blood, the section being introduced by a chapter upon the blood under normal conditions, by Dr. Louis Jenner. This chapter will be found exceedingly useful to those interested in this subject; it is concise and up-to-date, and deals with the more generally employed technique. The diseases of the blood themselves are dealt with by Dr. Sidney Coupland.

In the case of the work before us, the reviewer finds himself in rather an anomalous position in that the editor has written no preface, so that it is difficult to know by what standard the book should be judged. From a careful perusal of it we should place it mid-way between a book of reference and an ordinary text-book of medicine. Had it contained fuller references to the literature it might almost have ranked as a reference-book; as it is, it will no doubt fill a very useful place, which it thoroughly deserves to do, in the library of the advanced medical student and the practitioner.

A NEW CLASSIFICATION OF THE REPTILES.

Beitrag zur Systematik und Genealogie der Reptilien. By Prof. Max Fürbringer. Pp. 91. (Jena: Fischer, 1900.) Price Mk. 2.50.

IN the year 1873 Prof. Fürbringer, who has quite recently succeeded his illustrious master in the chair of comparative anatomy at Heidelberg, commenced to publish a series of contributions to the morphology of the pectoral girdle of reptiles, with special reference to the myology, the fourth and concluding part of which has now appeared. This highly elaborate piece of work is supplemented by a chapter entitled "Beitrag zur Systematik und Genealogie der Reptilien," in which the author sets forth his views on the phylogenetic arrangement of the class Reptilia.

As regards the origin of reptiles, the numerous fossil remains with which we are already acquainted seem to indicate so complete a passage from the Stegocephalous Batrachians, that the question at issue has lately been where to draw the dividing line between the two classes, an uncertainty which is further emphasised by the fact that the Microsauria, such as *Hylonomus* and *Petrobates*, of Carboniferous age, placed by most authorities among the Stegocephala, are included in the Reptilia by Prof. Fürbringer. From a knowledge of these connecting forms the conclusion must, it seems, follow that the ancestors of the Reptilia proper, themselves probably derived from Crossopterygian Fishes, as believed by Cope, Baur, and many other modern zoologists, possessed a skull with numerous membrane bones roofing over the temporal and occipital regions and with an immovable quadrate, that they belonged, in fact, to the type designated by Cope as monimostylic. In the process of evolution, in the series known as the Squamata (lizards and snakes), the predominant modern reptilian type, the number of membrane bones having been reduced and the temple left more and more unprotected, the quadrate became free and more or less movably articulated to the squamosal and supratemporal (streptostylic skull of Cope). The direction of the line of evolution in this instance, running as it does concurrently with the reduction and disappearance of the limbs, seems clear enough, and it is further supported by geological data, all early Reptiles and Batrachians being monimostylic without a known exception, whilst the streptostylic types appear first in the Jurassic as Lacertilia, to be followed by Snakes in the Eocene.

These conclusions are, however, set aside by Prof. Fürbringer. For him, the streptostylic condition is the primitive one, and, from the partial homology which he believes to have established between the spheno-pterygo-quadrate muscle of the Lacertilia and the *tensor veli maxillae superioris* of Selachians, he is led to look upon the condition exhibited by Geckos and Monitors as nearer the original one than that known in *Sphenodon*, in which the said muscle is much reduced. From this sole consideration, and by the purely gratuitous assumption that some early Rhynchocephalians, such as *Kadaliosaurus*, and Microsaurians may eventually prove to have been streptostylic, the author thinks himself justified in holding that the ancestral types from which the Lacertilians have been derived cannot be sought for among either the Stegocephalians or the Rhynchocephalians with the cranial structure of which we are at present acquainted, but that they will be found to be connected with some primitive hypothetical Amphibian type in which the quadrate was movably articulated with the skull, as in the lowest form of living Selachians.

"That such primitive streptostylic Amphibians have once existed, is rendered probable by the facts ascertained in the ontogeny of the living Amphibians. Probably streptostyly became converted into monimostyly as, in the course of evolution, their originally superficial apparatus of dermal bones became more and more intimately connected with the quadrate, the mobility of which consequently lessened and finally completely ceased."

This reasoning, by which, on the ground of the imperfections of the geological record, chronological indications are absolutely ignored, is not likely to meet with general favour. After the multitude of well-preserved Carboniferous and Permian "Eotetrapoda" which have lately been discovered and described by Credner, Fritsch and others, it will be difficult to accept the author's teaching that we know practically nothing of the progenitors of existing reptiles, and that these must be connected through a series of hypothetical Proamphibia or Protetrapoda with equally hypothetical Selachian-like animals.

As a consequence of the above assumption, the new classification differs fundamentally from those hitherto based on phylogenetic considerations, in this, that the Streptostylia s. Squamata, with the two orders Lacertilia and Ophidia, are placed at the base of the series. The Rhynchocephalia, Acrosauria, Microsauria and Ichthyopterygia are associated with them in a subclass Tocosauria. A second subclass, Theromorpha s. Theromora, includes the Dicynodonts, Anomodonts and Pariasaurians; a third, Synaptosauria, the Mesosaurians, Sauropterygians

and Chelonians; whilst in a fourth, Archosauria, the Crocodilians, Dinosaurs and Pterodactyles are brought together. Little objection will be found to the composition of the second and fourth subclasses, as it answers to the views held by almost all modern classificators. But it is difficult to believe that the proposal to group the Squamata, Rhynchocephalia and Ichthyosauria in a group equivalent and opposed to the one including Mesosauria, Plesiosauria and Chelonia, will meet with ready acceptance. It would, however, carry us too far to enter on this occasion into a discussion of the reasons that have determined the author to adopt such an arrangement.

But it may not be out of place here to enter a protest against the introduction of new terms for higher divisions, such as Patagiosauria for the well-known Ornithosauria or Pterosauria, Gecko-Chamæleontes s. Uroplatimorpha for the group already named Uroplatoidea by Gill and Geccovarani by Cope, on the mere ground of the new names being more expressive. *À propos* of the last-named division, it is indeed startling to learn that the long-sought ancestor of the Chameleons is believed by Prof. Fürbringer to be approximated by the curious *Uroplates* of Madagascar which, formerly placed with the Geckos, was first raised to family rank on the ground of the difference in the shape of the clavicular arch. However, the arguments brought forward by the learned professor in favour of this hypothesis do not seem very convincing.

The limits assigned to this notice do not permit of attention being drawn to the many other salient points in the new classification, and to the incidental remarks on the relationships which birds and mammals bear to the reptiles. Suffice it to say that Prof. Fürbringer's work is, like everything we owe to his marvellous industry, most elaborate and careful, and that the very complete bibliographical indications that accompany it constitute in themselves a valuable mine of information for the student of the morphology and taxonomy of the reptiles.

G. A. B.

OUR BOOK SHELF.

A Practical Guide to Garden Plants. By John Weathers. Pp. 1192 + xii. (London: Longmans, Green and Co., 1901.) Price 21*s*. net.

THE garden plants here dealt with are those which are hardy enough to be cultivated in the open air, and they comprise not only ornamental plants but fruits and vegetables. A well-constructed glossary precedes the body of the work. The earlier portions are devoted to the life-history of cultivated plants, which is well done so far as it goes, but which would bear to be considerably expanded. It is rather misleading to call oxygen, carbon, hydrogen, nitrogen and the other elementary substances which the chemist finds in plants, different kinds of food. They are the materials of which food is made, but not the food itself.

The bulk of the work is made up of descriptions of the various hardy plants generally grown in gardens, together with indications for their cultivation.

The plants named are arranged in their natural orders, which is a great boon to the amateur, greatly facilitates the acquisition of knowledge, and adds to the interest of the plant. "If the cultivator," says the author, "has even only a slight knowledge of the way in which plants have been grouped more or less naturally by botanists, he may, by the aid of his books, run the unknown plant very close, if not quite, to its own group from the characters he sees. But if his books have the plants arranged simply in alphabetical order according to their names and not according to their relationships, he may as well give up his search at once unless he has the time and inclination to wade through every name from A to Z. Indeed, descriptive plant-books, arranged in purely alphabetical order, are only of value when the proper name of the plant about which information is required is already known."

From long experience we can confirm the author's statement. It is the fashion nowadays to neglect the comparative study of plants as they now exist, but, looking at the matter from a utilitarian point of view, it is of much greater use to be able to recognise the distinctions between one natural order and another than it is to indulge in speculative and conjectural genealogies. In any case, a knowledge, even though it be slight, of the principal natural orders adds greatly to the interest of a garden and often affords useful indications for cultivation. Mr. Weathers has sometimes supplied English names for the orders which appear to us as to be unnecessary—for instance, why should we have to learn that the Magnolia order is called the Lily-tree order, or why should the Leguminosæ be called the Laburnum and Broom order? The Latin names of the orders present, as a rule, little or no difficulty to those who really desire to know them. For those who do not, it is not necessary to put one's self to inconvenience. This portion of the work is excellent for reference purposes, and must have entailed great labour on the author.

The sections relating to fruit and vegetables are not so satisfactory, but, on the whole, the book is well calculated to satisfy the requirements of the amateur and of the professional gardener, the more so as it is provided with an excellent index.

Ausgewählte Methoden der Analytischen Chemie. By Prof. Dr. A. Classen. Erster Band. Pp. xx+940. (Brunswick: Vieweg und Sohn, 1901.)

THE first impression which this volume on select methods of analysis conveys is entirely favourable. The book is well printed, tastefully bound, and furnished with those delicate illustrations of apparatus which are characteristic of German chemical books.

The chief desideratum in a work on analysis is that the author shall not only be a skilled analyst, but that he shall have had personal experience of the methods which he describes.

Prof. Classen's connection with analytical chemistry, especially with the introduction of electrolytic methods, is too well known to leave any doubt as to his qualifications as an analyst, and we are assured by him in the preface that "In diesem Buche sind demnach diejenigen Methoden vorzugsweise beschrieben worden, welche ich persönlich vielfach anwandte, oder welche durch meine Assistenten und Schüler oder von dritten Seite kritisch geprüft wurden."

We can only admire the zeal and industry of the author and his assistants in having been able to examine critically even half the methods described in these 900 pages of closely printed matter. In reviewing a book of this kind, one naturally turns to the description of processes with which one is familiar. Judged by this test it fully justifies its first impressions. It is furnished with that minuteness of detail which is requisite in any book on quantitative and especially technical analysis, as this professes to be.

In addition to the estimation and separation of the commoner metals, considerable space is devoted to the rarer ones, some of which, like cerium and its allies, have recently entered the field of technical chemistry.

It seems odd that in a work relating entirely to metals

so little mention is made of metallurgical methods of assaying, which are frequently employed, not only for estimating silver and gold, but in the technical analysis of lead and copper ores. J. B. C.

Recueil de Données numériques. Optique. By H. Dufet. Part iii. Pp. 787–1313. (Paris: Gauthier-Villars, 1900.)

THE second part of this invaluable collection of physical and chemical data dealt with the optical properties of solids, and has already been described in these columns (vol. lx. p. 28). The present (and concluding) volume contains tables showing the rotatory powers of crystalline bodies, liquids and solutions, interference colours produced when rays of white light strike normally upon a layer of air of a given thickness, and supplementary tables of refractive indices, standard wavelengths, optical properties of inorganic and organic bodies, and other data. In all cases full reference is given to the authority for the values tabulated. The Physical Society of France has done a service to science by arranging for the preparation and publication of these results, which have been gathered from many sources, and are frequently difficult of access.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Apatite in Ceylon.

A PARAGRAPH in Prof. Miers' interesting notice (NATURE, March 7) of the results of Dr. Grünling's mineralogical expedition to Ceylon may convey the impression that Dr. Grünling was the first person to recognise, and Dr. Schiffer the first to analyse, the sky-blue apatite of Ceylon.

Now Mr. H. Willett, of Brighton, handed me several years ago a beautiful transparent specimen which I at once identified as apatite though its colour was unusual. The sky-blue, prismatically developed crystals were embedded in a white dolomitic matrix. This specimen had been brought from Ceylon by Mrs. Willett. Its exact provenance was unknown, but some spot not far from Kandy and the railway thither was suggested as the probable locality. There can be little doubt that this specimen came from the neighbourhood of Wattegama, between Kandy and Matale, where Dr. Grünling obtained the apatite analysed by Dr. Schiffer. In the *Mineralogical Magazine* for April 1899 (p. ix) will be found a notice of a paper read by me before the Mineralogical Society on January 31, 1899, just two years ago, entitled "Analyses of Ceylon Apatite." Following this title occurs the paragraph: "Prof. Church exhibited blue apatites from Ceylon, one containing as much as 3·21 per cent. of chlorine, others only 0·63 and 0·34 per cent." The last of these three figures represents the percentage of chlorine found by me in Mr. Willett's specimen.

In discussing, in the autumn of 1898, the question of Ceylon apatite with Prof. Judd and Mr. F. W. Rudler, I found that the identification of this mineral did not seem at that time to have been published. Prof. Judd was good enough to supply me with specimens from another Ceylon locality (near Newara Eliya) and having a different matrix. Here the colour of the apatite was paler and its crystalline habit indistinct. This sample gave 0·63 per cent. of chlorine.

But by far the most interesting specimens were some imperfect tabular crystals sent to me in 1898 by a gem-merchant of Colombo. These were of a much richer blue colour than any of the other examples. Indeed, my Colombo friend's attention had been drawn to them by one of his "Moormen" having brought to him, some time previously, a perfectly transparent cut gem weighing five carats, which he offered as a blue spinel! I wrote for uncut specimens, which were soon procured from the same Moorman, but he had removed them from the matrix. The locality of these specimens proved to be Avisavelle. One of these crystals it was that gave me 3·21 as the percentage of chlorine. I may add that the dichroism of this variety closely resembled that of vivianite.

I would remark in conclusion that the number of Dr. Groth's *Zeitschrift für Krystallographie u. Mineralogie* in which the blue apatite of Ceylon is described was published last year, long after the notice of my paper had appeared in the *Mineralogical Magazine*. If any earlier communication on the subject has appeared I should welcome a reference to it.

A. H. CHURCH.

Maps in Theory and Practice.

EVERY advanced treatise on astronomy defines and explains certain kinds of map projection; but in all these accounts I have been struck with the absence of any notice of the particular kind of projection with which we are most familiar—the kind usually employed for representing the world in hemispheres; in fact, the commonest kind of map projection.

I have for the first time come across a notice of it, at p. 126 of the February number of the *American Journal of Science*, in the following terms:—

"The method of projection almost universally employed by geographers for representing hemispherical surfaces is the so-called globular projection, invented in 1660 by the Italian Nicolosi (Germain, 'Traité de Projections des Cartes Géographiques,' Paris, about 1865). The equator is divided into equal parts, and the meridians are circular arcs uniting these points with the poles. The parallels are likewise circular arcs, dividing the extreme and central meridians into equal parts."

As three points suffice for determining a circle, this definition is complete for the mapping of a hemisphere extending from pole to pole. To apply it to a smaller portion of the earth's surface, let the hemisphere be so taken that this portion is centrally placed between east and west; then the central meridian will be straight.

As it is desirable that theory should be kept in touch with practice, I would commend this subject to the attention of teachers of geography and astronomy. J. D. EVERETT.

11 Leopold Road, Ealing, W., March 11.

Early Observations of Volcanic Phenomena in Auvergne and Ireland.

MR. G. P. SCROPE ("Extinct Volcanos of Central France," ed. 2, 1858, p. 30) describes how Guettard and Malesherbes, returning from Italy, met Faujas de St. Fond at Montélimar in 1751, and, in his company, founded the theory of the volcanic origin of the mountains in the Vivarais. Guettard and Malesherbes thence proceeded to Auvergne, where M. Ozy, a chemist of Clermont-Ferrand, acted as their guide. Ozy knew his ground well, and had already observed the general aspect of the rocks, since Guettard (Mém. Acad. roy. des Sciences, 1752, p. 37) says that he "m'assura . . . que je trouverois par-tout une même structure & les mêmes matières qu'il m'avoua ingénument n'avoir jamais reconnues pour ce qu'elles étoient."

Sir A. Geikie has justly written of the discoveries of Guettard ("Anc. volcanoes of Gt. Britain," preface), "To France, which has led the way in so many departments of human inquiry, belongs the merit of having laid the foundations of the systematic study of ancient volcanoes."

Considerable interest, therefore, attaches to a letter from Ozy, published by Faujas de St. Fond in 1778 ("Recherches sur les volcans éteints du Vivarais," p. 434), and written in reply to inquiries as to what authors had first visited the volcanoes of Auvergne. Ozy refers somewhat casually to his meeting with Guettard, which was already well known through the information provided by him, and fully acknowledged in Guettard's paper. But he states that a year before, that is, in 1750, he was visited by "Olzendorff," an Englishman, and "M. Bowls, irlandois," who came to inspect the adjacent lead-mines. He continues: "Nous montâmes ensemble au *Puy de Dome*, & ce fut là que j'appris pour la premiere fois à connoître les *cratères*, les laves, &c., car auparavant je n'étois pas plus instruit sur cet objet que les autres habitans de cette province."

It seems hardly possible to construe this passage, written in answer to a direct inquiry from St. Fond, into a confusion of the two ascents. The "ensemble" refers to Olzendorff and Bowls; "la premiere fois" can hardly refer to events of the subsequent year. "Bowls," moreover, was, with high probability, William Bowles the mineralogist, who is known to have

been born in Cork, and who published his work on the natural history of Spain in Paris in 1776. It would be very interesting to trace any conclusions as to extinct volcanoes that were current in Bowles's mind as early as 1750. Ozy is not likely to have made a show of his previous knowledge to men of established position like Guettard and Malesherbes, who had honoured the local apothecary with a call. He listened to their exposition of the craters, and "avoua ingénument" that he was much surprised at what he heard. After all, it was Guettard who took the matter up absolutely fresh from the beginning, and whose memoir made it for the first time public knowledge.

Bowles may have come from Catalonia, and may have formed his opinions there. I make no mention of Olzendorff, of whom I have no further trace; but the fact that Bowles instructed Ozy at Clermont, if the above contention is correct, a year before Guettard had formed his conclusions, and in an age rife with unfounded speculation, marks him as a geological observer deserving of more credit than he has yet received. I called attention to Ozy's letter in *Knowledge* for 1898, p. 266, and have since made inquiries through friends in Cork and elsewhere; but the present family of Bowles in Cork, formerly Boles, can furnish no data as to the life of the mineralogist.

An interesting inquiry also arises as to when the Giant's Causeway in Antrim was first regarded as a lava-flow. What did Bowles know of this phenomenon? Its detailed appreciation, from a geological point of view, is usually ascribed to Whitehurst, in the second edition of his work in 1786. But Faujas de St. Fond in 1778 calls many of the French lava-flows "chaussées," and clearly shows his own conclusions when he styles certain examples with good columnar jointing "pavés des géans."

GRENVILLE A. J. COLE.

Royal College of Science for Ireland, Dublin, March 1.

Probability—James Bernoulli's Theorem.

IT may possibly be of some little interest to notice that the theorem in probability, which goes by the name of James Bernoulli's theorem, alluded to in my letter to NATURE of December 13, 1900 (p. 154), admits of a treatment somewhat more elementary than the usual one.

The theorem may be stated thus:—If p is the probability of a given event, and n the number of times considered; as n increases without limit, the probability that the ratio of the number of times in which the event happens to the whole number of times (n) will only deviate from p within limits of excess and defect, which decrease indefinitely as n increases without limit, is a probability which approaches indefinitely to unity as its limit.

In Laplace's demonstration (see Todhunter's "History of Probability," art. 993) Stirling's theorem, for the evaluation of factorials, is used in the first step; in the second step the theorem of Euler,

$$\Sigma y = \int y\,dr - \tfrac{1}{2}y + \tfrac{1}{12}\frac{dy}{dr} - \dots$$

which is also implied in the usual proof of Stirling's theorem; and, finally, the result depends on the evaluation of the well-known definite integral $\int_0^\tau e^{-t^2}dt$.

Further, it is essential to this demonstration to make the limit of deviation in excess from the ratio p equal to the limit of deviation in defect, for then as members of the series, which represent the probability sought, equidistant from the middle of the series contain certain terms equal in magnitude and of contrary sign, these terms cancel in the addition of such pairs, and are thus got rid of.

It may be shown that the general result of Bernoulli's theorem may be got without the above described use of Euler's theorem (*i.e.* the second use of it), without using the evaluation of $\int_0^\tau e^{-t^2}dt$, and without making the limits of excess and defect equal. These limits may have any ratio whatever.

Let q be the probability that the event does not happen, so that $p+q=1$.

Let the whole number of times considered be $y+x$. Since this is to increase without limit, we may suppose $p(x+y)$ and $q(x+y)$ always integers.

Let P be the probability that the number of the times in which the event happens be between $p(x+y)+ax$ and $p(x+y)-bx$ where $(a+b)=1$, so that x represents (so to speak) the range of the variation, a and b may have any ratio to one another. Assume that $y=mx^{2(1-\kappa)}$, where κ may be as small as we please, but finite. Thus P is the probability that the ratio of the times when the event happens to the whole number of times shall not exceed p by more than $\frac{ax}{x+y}$, or fall short of p by more than $\frac{bx}{x+y}$; limits which vanish when x and y are infinite.

Let P_1 = probability that the number of times in which the event happens is less than $p(x+y)-bx$, and P_2 the probability that it exceeds $p(x+y)+ax$. Then $1-P=P_1+P_2$.

$$P_1 = p^{x+y} + (x+y)p^{x+y-1}q + \dots + \frac{(x+y)!\; p^{p(x+y)+ax+1}q^{q(x+y)-ax-1}}{\{p(x+y)+ax+1\}!\;\{q(x+y)-ax-1\}!}.$$

Now P_2 evidently = the probability that the number of cases in which the event does not happen is less than $q(x+y)-ax$, and therefore the series for P_2 is derivable from that for P_1, by interchanging p and q, and by interchanging a and b. These values of P_1 and P_2 may, of course, be also got from the equation

$$P_1+P_2=(p+q)^n-P.$$

P_1 is evidently less than the geometrical progression of which the sum is

$$\frac{(x+y)!\; p^{p(x+y)+ax}q^{q(x+y)-ax}}{\{p(x+y)+ax\}!\;\{q(x+y)-ax\}!}\cdot\frac{\left\{\frac{p}{q}\cdot\frac{q(x+y)-ax}{p(x+y)+ax+1}\right\}^{q(x+y)-ax+1}-1}{\frac{p}{q}\,\frac{q(x+y)-ax}{p(x+y)+ax+1}-1}$$

By Stirling's theorem, x and y increasing *ad. inf.*

$$(x+y)! = (x+y)^{x+y+\frac{1}{2}}e^{-(x+y)}\sqrt{2\pi}\left(1+\frac{1}{12(x+y)}+\dots\right)$$

$$= y^{x+y+\frac{1}{2}}\left(1+\frac{x}{y}\right)^{x+y+\frac{1}{2}}e^{-(x+y)}\sqrt{2\pi}\left(1+\frac{1}{12(x+y)}+\dots\right),$$

and similarly for the other factorials.

Thus the above expression becomes

$$\frac{1}{\sqrt{2\pi pq}}\cdot\frac{\left(\frac{1}{12(x+y)}+\dots\right)}{\left(1+\frac{1}{12(p(x+y)+ax)}+\dots\right)\left(1+\frac{1}{12(q(x+y)-ax)}+\dots\right)}\cdot$$

$$\frac{\left(1+\frac{x}{y}\right)^{x+y+\frac{1}{2}}}{\left(1+\frac{(a+p)x}{py}\right)^{p(x+y)+ax+\frac{1}{2}}\left(1+\frac{(q-a)x}{qy}\right)^{q(x+y)-ax+\frac{1}{2}}}\cdot\frac{1}{y^{\frac{1}{2}}}\cdot$$

$$\frac{\left\{\frac{p}{q}\,\frac{q(x+y)-ax}{p(x+y)+ax+1}\right\}^{q(x+y)-ax+1}-1}{\frac{p}{q}\,\frac{q(x+y)-ax}{p(x+y)+ax+1}-1}.$$

The limit of the second factor is unity. The third factor may be shown to become in the limit

$$\frac{1}{e^{\frac{a^2}{2mpq}}}x^{2\kappa}.$$

The limit of

$$\left\{\frac{p}{q}\,\frac{q(x+y)-ax}{p(x+y)+ax+1}\right\}^{q(x+y)-ax+1}$$

is the limit of e^{-cx}, and the limit of

$$y^{\frac{1}{2}}\left(\frac{p}{q}\cdot\frac{q(x+y)-ax}{p(x+y)+ax+1}-1\right)=-hx^{\kappa},$$

where c and h are positive constants. Hence the limit of the product of the factors is zero—that is, the limit of P_1 is zero, and evidently also the limit of P_2.

Hence the limit of P is unity.

The range of the deviation (x) is greater in this proof than in the usual one, for in the latter x would vary as $y^{\frac{1}{2}}$ as against $y^{\frac{1}{2-2\kappa}}$ where κ may be as small as we please.

A further simplification would be introduced by a method of evaluating the series P_1 or P_2 without the use of Stirling's theorem. Such a method has been given me by Mr. G. G. Berry, of Balliol College, and may be briefly described as follows:—

If in the expansion of $(p+q)^n$ we stop t terms before the greatest, the truncated series has a smaller sum than the G.P., which has the same two final terms. If t^2 is great as compared with n, the G.P. has a sum which vanishes compared with its final term multiplied by $\sqrt{n}$. But the product of the greatest term of $(p+q)^n$ and $\sqrt{n}$ is finite; for the sum of $\sqrt{n}$ terms on either side of the greatest <1, and the ratio of the greatest term to a term distant from it by $\sqrt{n}$ places is—

$$\frac{\left(1-\frac{1}{pn}\right)\left(1-\frac{2}{pn}\right)\cdots\left(1-\frac{\sqrt{n}-1}{pn}\right)}{\left(1+\frac{1}{qn}\right)\left(1+\frac{2}{qn}\right)\cdots\left(1+\frac{\sqrt{n}}{qn}\right)},$$

which has a finite limit. J. COOK WILSON.

Oxford.

A Tree Torn by Lightning.

I ENCLOSE two photographs of an oak tree struck by lightning, which seem of interest.

The storm, one of considerable violence, occurred on July 27, 1900, and continued for several hours. The tree stood by the side of a road which runs over the Chilterns from Ipsden, a little village about five miles from Wallingford and ten from Henley. It was standing at the western edge of a small stretch of woodland. The opposite side of the road was quite clear and sloped down to the plain.

FIG. 1.

On examination, the bark was found to be completely stripped off and flung on one side; a large branch was torn away, and the fractured end was extraordinarily splintered and smashed. So far as I saw there were no signs of charring.

The inner surface of the bark was marked longitudinally with thin wavy lines, very close-set, of which the crests were about ¼ inch apart.

The first photograph gives a general view of the tree; the second represents the lower side of the bent portion of the trunk, and shows very clearly the rending effect of the lightning on a fibrous tissue.

FIG. 2.

The photographs were taken about a fortnight after the tree was struck, during which time there had been much wind and rain. PERCY E. SPIELMANN.

Adaptation of Instinct in a Trap-door Spider.

THE following extract from the *Sydney Bulletin*, January 12, sent to me by a correspondent in Western Australia, recounts an observation sufficiently interesting, I think, to be reprinted and put on permanent record in a scientific periodical:—"A friend of mine noticed near his camp a trap-door spider run in front of him and pop into its hole, pulling the 'lid' down as it disappeared. The lid seemed so neat and perfect a circle that the man stooped to examine it, and found, to his astonishment, that it was a sixpence! There was nothing but silk thread covering the top of the coin, but underneath mud and silk thread were coated on and shaped convex (as usual). The coin had probably been swept out of the tent with rubbish."

As is well known, the doors of trap-door spiders' burrows are typically made of flattened pellets of earth stuck together with silk or other adhesive material. The unique behaviour of the spider in question showed no little discrimination on her part touching the suitability as to size, shape and weight of the object selected to fulfil the purpose for which the sixpence was used. R. I. POCOCK.

March 6.

Protective Markings in Cats.

IT will probably appear to many—as it does to myself—that the development of a protective mechanism in a domestic animal is not likely, and for several reasons—such as the shortness of time at the disposal of the race, and, of course, to their large independence of stress of circumstances. Still it may be admitted that the domestic cat bears its subjugation to man more lightly than many of the other creatures which he has tamed. The particular mark above the eye to which your correspondent refers (p. 441) has also been pointed out by Mr. Wallace in the dog. It may interest those of your readers who are not aware of the fact to learn that the tiger has a largish and very bright white spot upon the back of the ear. When the ears are directed forwards this spot is exceedingly conspicuous from in front (as any one may verify upon the fine pair of tigers now in these gardens); and, in the dimness of a cave or a thicket, might conceivably produce an impression of alertness when the animal was really sleeping.

Zoological Society's Gardens. FRANK E. BEDDARD.

FURTHER OBSERVATIONS ON NOVA PERSEI.[1]

SINCE the preliminary note on this star was communicated to the Royal Society on February 28, observations have been possible on the nights of February 28, March 1, 3 and 5, and twenty-four photographs of the spectrum have been taken with the instruments before detailed.

It may be stated generally that the light is slowly waning. On February 28 the star was only slightly brighter than α Persei. On March 1 it was estimated as about equal to α Persei, *i.e.* about 2·0 magnitude. When it was again visible, on the evening of March 3, it was distinctly less bright than β Persei, and its magnitude probably near 2·5. On the 5th its estimated magnitude was 2·7.

The above refers to the visual brightness. A photograph of the region occupied by the Nova on March 3 showed it to be photographically brighter than α Persei.

General Description of the Spectrum.

The photographs show that the bright hydrogen lines are successively feebler as the ultra-violet is approached, and the whole of the series of hydrogen lines have, during the past week, become relatively brighter with respect to the remaining lines and the continuous spectrum. The spectrum extends far into the ultra-violet.

Among the changes which have taken place in the visible part of the spectrum, it may be mentioned that, while the lines of hydrogen have become relatively brighter during the past week, the remaining lines, with the possible exception of the prominent one at λ 5169, have become distinctly dimmer. There has also been a diminution of the intensity of the continuous spectrum. The line in the yellow, the identity of which has not yet been definitely determined, has gradually decreased in intensity with the diminution of brightness of the star. The bright green-blue F line of hydrogen has become more conspicuous as the neighbouring green lines have become fainter, and the bright C line is intensely brilliant.

From all these causes, which give us blue light on the one hand and red on the other, the star should present to us the precise quality of red which has been observed.

Colour.

At discovery the star was described as bluish-white. No observations on its variation in hue during its brightening were possible, owing to unfavourable weather conditions. The observations during the period of decline have indicated a change to the present colour of a decided claret-red. In comparison with this it is interesting to note that in the case of the Nova which appeared in 1604, Kepler alludes to purple and red tints assumed by the star.

Changes in the Photographic Spectrum.

Between February 25 and March 5, to take the extreme difference of dates on which photographs were obtained, it has been noted that while some of the dark lines were absent on the later date, either new lines had come in or previously feeble lines had become intensified. There has not yet been time to determine accurately the positions of these lines. The appearance of the bright lines of hydrogen, which I described as being reversed on February 25, had very materially changed by March 3.

In inspecting the dark band representing the bright hydrogen at Hϵ, two darker fine lines are seen nearly coincident in position with the edges of Hϵ in the spectrum of α Persei photographed on the same plate.

The appearance in the case of the "F" line (Hβ), is seen by the accompanying light curve (Fig. 1).

[1] Abridged from a paper read at the Royal Society on March 7, by Sir Norman Lockyer, K.C.B., F.R.S.

No doubt the differences in the appearances are due to a fact that at Hϵ we are dealing with the lines both of H and Ca.

Rough measurements on the bright line Hβ show that the interval between the centres of the two extreme maxima shown in the light curve corresponds to about 25 tenth-metres. This would give a differential velocity of 960 miles per second between the different sets of hydrogen atoms in the bright line swarm itself.

It may be, then, that the appearances described as reversals of the hydrogen lines on February 25 were but the beginning of the subsequent changes.

The comparisons with stars which have been taken with the slit-spectroscope on each evening of observation, indicate that no great change in the velocity of the dark line component has occurred. So much, however, cannot

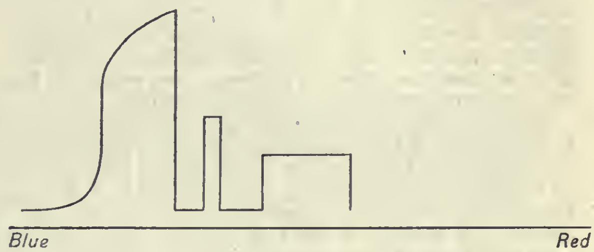

FIG. 1.

be said of the bright lines in which a change has been observed.

In addition to the hydrogen lines, the strong lines in the green already ascribed to iron appear to be double in the photographs most recently obtained.

Comparison with α Cygni.

The view of the apparent similarity between the spectra of Nova Persei and Nova Aurigæ, to which I drew attention in my previous paper, has been strengthened by the comparisons which have since been made.

The bright lines in the spectrum of Nova Persei are so broad, especially in the blue and violet, that accurate determinations of their wave-lengths are difficult to obtain. The lines less refrangible than F, however, besides being more isolated, are narrower than those in the more refrangible part of the spectrum. A direct comparison of these with the lines in the spectrum of a star which is known to contain the enhanced lines of iron, &c., has been considered a better method of arriving at some definite conclusion as to the connection between the Nova lines and the enhanced lines than that of determining the wave-lengths of the broad lines and comparing the results with the known wave-lengths of the enhanced lines.

The best star for this purpose is α Cygni, but, unfortunately, no good photograph has been obtained at Kensington of the green portion of the spectrum of that star. The star most nearly approaching α Cygni in relation to enhanced lines is α Canis Majoris, which, in the Kensington classification, has been placed nearly on a level with the former star, but on the descending side of the temperature curve. In the spectrum of this star the enhanced lines of iron at $\lambda\lambda$ 4924·1, 5018·6, $\begin{cases} 5169·0, \\ 5169·2 \end{cases}$ and 5316·9 occur as well-marked lines. This spectrum has been directly compared with that of Nova Persei, taken with the same instrument, and the fact that all the lines apparently coincide affords good evidence that the connection is a real one, and that the first four strong Nova lines beyond F on the less refrangible side are the representatives of the enhanced lines of iron. These are the only enhanced lines which occur in that part of

the iron spectrum, with the exception of a weak one at λ 5276. There is only a trace of this line in the spectra of either the Nova or α Canis Majoris which have been compared. In the spectra of the Nova obtained with lower dispersion, however, a line is distinctly shown in this position, though it is considerably weaker than the four lines previously mentioned.

The absence of the strong lines which are familiar in the arc spectrum and in the ordinary spark spectrum in this region is to be ascribed to higher temperature; experiments which are in progress show that under certain conditions the two lines λλ 5018·6 and 5169 are by far the strongest lines in the spectrum of iron between λ 500 and D, while that at λ 4924·1 is distinctly stronger than any of the well-known group of four arc lines in which it falls.

The published wave-lengths of the lines of Nova Aurigæ show that the same lines were present in that star. Further investigations of the spectrum of Nova Aurigæ have strengthened the conclusion that most of the lines, after we pass from those of hydrogen, are enhanced lines of a comparatively small number of metals.

When the inquiry is extended into the regions more refrangible than Hβ, the evidence in favour of the similarity of the spectra of the two Novæ with that of α Cygni is not so conclusive, because of the greater breadth of the lines (since the spectra have been obtained by the use of prisms) and because of the fact that in this region the enhanced lines of iron frequently occur in groups.

In the region between Hδ and Hγ, however, there is a well-marked enhanced line of iron at λ 4233·3, and also two doubles at λλ 4173·7, 4179·0, and λλ 4296·7, 4303·3, and a comparison of α Cygni with Nova Persei indicates that these fall on broad bright bands of the Nova spectrum.

NORMAN LOCKYER.

MR. BORCHGREVINK'S ANTARCTIC EXPEDITION.[1]

MR. BORCHGREVINK succeeded in an enterprise of which he may be justly proud. Unknown and without external influence, by the force of his immense ambition and determination, he obtained the support of a man of great wealth, and unaided, if also untrammelled, by Government, learned societies or committees of any kind, he equipped an expedition, selected a scientific staff, spent a winter on land in the Antarctic regions for the first time in history, and made his way to a point nearer the South Pole than had ever been reached before. For doing this he deserves praise and honour. With his motives we have no concern; they appear to have been partly commercial and partly scientific, but in these columns we can only treat the expedition from a purely scientific point of view, forming our opinions from the facts placed before us in the book.

Mr. Borchgrevink chose his ship well, and she proved to be as stout and powerful a steam-whaler as ever put out from Norway. He chose his scientific staff well, and they appear to have worked conscientiously and to have obtained results which cannot fail to advance knowledge if they are properly discussed and published. He chose his sailing master, Captain Jansen, well, and he appears to have conducted the expedition without a hitch or any trace of insubordination. Mr. Borchgrevink was able to repeat in his steamer Sir James Clark Ross's sailing-ship voyage, and saw again Mounts Erebus and Terror; he landed on the southern ice, and advanced a few miles beyond the edge of the previously known world.

The book is short—an excellent thing in accounts of travel; the author has a certain power of observation and description, as the chapter on the habits of penguins and many little episodes of personal adventure show. His illustrations are remarkably fine, admirable reproductions of good photographs, and they are introduced with a lavish hand.

This is the bright side of the medal; the reverse is not so pleasing. Mr. Borchgrevink would have done better if he had had another chronicler, for his literary style does him less than justice. We can excuse an author, whose forte is action rather than study, for attributing incorrect titles to English men of science, but he might surely be expected to give correctly the names of his own distinguished countrymen, amongst whom Dr. Hjort appears as *Hjorth*, and Dr. Reusch in one place as *Reush* and in another as *Rusch*. Although the book is small we can hardly attribute these slips to anything but haste in correcting the proofs. We wish we could find an equally satisfactory explanation of other errors of a more serious kind.

We fear that Mr. Borchgrevink did not set his ambition high enough, and did not endeavour to make himself acquainted with the elementary principles of the various sciences which the members of his staff were pursuing. During the long Antarctic night he might easily have learned from his skilled assistants more than sufficient to have enabled him to give an intelligible sketch of the work of his expedition, even if time had been wanting at an earlier period. That he did not do so is to be inferred from the following circumstances, to which we call attention with real regret and which we would have passed over gladly were it not that the objects of the expedition have been generally spoken of as scientific.

On p. 63 there is given what purports to be a fully worked example of the calculation of the longitude from observations of the sun taken near Balleny Island,[1] by means of a Cary 10-inch sextant. The index error was found to be "14 in." off the arc—a possible printer's error for 14″, one would think; but further down the error is given as 14′ 0″. However, the sun's semidiameter is also estimated at the excessive value of 16° 17′ 1″, and this gives us a clue to the system of notation employed for the corrections, though not for the instrumental reading. It is simply to write minutes as degrees, seconds as minutes and decimals of a second as seconds. Working out the calculation on this assumption the final corrected altitude is obtained as stated. On p. 64 the curious blunder of "Lysin Sq.," probably intended for "Log Sin²," and several others equally absurd have escaped the author's vigilance, and the logarithms set down are not what we would expect.

Is this an elaborate joke played by the author on the public, or is it a joke played on the author by some person unknown and not detected by him? We cannot think that it was meant seriously, and we cannot see why the example was ever given, as no one has any interest in disputing the position of Balleny Island. The actual figures and working of the really critical observation which convinced Mr. Borchgrevink that he had got further south than Sir James Ross might have been quoted reasonably enough, but are not. If any credence is to be given to the position of the expedition at any date, the serious question raised by this worked specimen must be answered.

On p. 136 we read, "Only Jupiter and its stars and Centauri were visible." So much for astronomy.

With regard to meteorology the same indifference to figures occurs. In more than one place the height of the barometer is given in the form "29.7.1," although elsewhere the readings are expressed in the usual way. The vaguest references are made to instrumental observations; for instance, a graphic account is given of the difficulty of placing a thermograph at 2000 feet on Cape

[1] "First on the Antarctic Continent; being an account of the British Antarctic Expedition, 1898–1900." By C. E. Borchgrevink, F.R.G.S., Commander of the Expedition. With portraits, maps, and 186 illustrations. Pp. xvi+334. (London: George Newnes, Ltd., 1901.)

[1] Balleny Island is stated, on p. 3, to be a volcano 12,000 feet high; here there is evidently some confusion with Mount Erebus.

Adare, and of returning for it a week later; but its readings are not noted. The "anti-cyclonic theory" is referred to, but neither discussed nor explained.

"Characteristic stratification of the rocks" is referred to on p. 223, and some of the photographs do appear to show lines of bedding; but we are left in doubt as to whether the author realises the great interest of discovering such rocks on the Antarctic continent. In the preliminary report on the rock-specimens by Mr. J. T. Prior, in the appendix, there is no reference to anything most like stratified rocks than a "pale green slate and quartz grit," of which no particulars are given. On p. 264 we read of "a huge cauldron, the bottom of which was even below the sea-level, but guarded against the waters of the cove to the west by a narrow ridge of brimstone"; but this unusual structure does not seem to have been investigated.

As to biology, birds are always referred to by their full names, generic and specific; but the seals are simply termed "Weddelli" (a name used to distinguish this seal from the sea-leopard) or "Rossii," as the case may be, without indication of their genera. Biological theory is handled thus in speaking of what is called "bi-polarity" (p. 232).

"The existence of organisms does not develop from the presence of the possibility of existence for these, but because the element necessary for the development of these organisms was brought into conditions which favoured its development into a complete organism. It seems thus that the fount whence the element of these organisms rises exists both within the Arctic and Antarctic Circles, apparently without any communication through the intermediary zones."

In dealing with geography there is an equal want of sense of proportion, definite information or clear ideas. The description of the coast of Victorialand is far less definite than Ross's. No connected account is given of the land-explorations which were carried out near Cape Adare. Mr. Borchgrevink states that he was away from his camp for so many days or weeks, but gives the vaguest descriptions of where he went or what he saw. As he climbed a glacier on one occasion—"step by step we rose until we were a few thousand feet up, as indicated by the aneroid." This is offering a stone to the reader who hungers after definite information. The log of the crossing of the pack by the *Southern Cross* on four separate occasions might be expected to yield most important hints to the forthcoming Antarctic expeditions; but details are only given of one of these crossings. The description of the southern ice-barrier, which was dismissed in a few lines by Mr. Borchgrevink in his paper to the Royal Geographical Society, was looked forward to with the keenest interest; but in this matter we find the most tantalising reticence. The famous ice-barrier, we are told, is only from 60 to 70 feet high (about one-third of the height assigned by Ross), and at the point where a landing was made it was only 2 or 3 feet, and rose gradually southward to the normal height. There is no information as to the depth of the water alongside the barrier, a point of the most vital moment. One sounding does, indeed, figure on the map, but the exact point to which it applies is not indicated. The remarkable fact that the position of the ice-barrier was found to be many miles further south than reported by Ross is not commented on. A long digression on icebergs and pack-ice is interposed in the middle of the twelve lines of description given to the part of the world where no one had ever been before. It concludes, "With a sufficient number of reindeer, sledges and dogs, and a very small party of scientific men, I believe that a great southern latitude may be reached on this ice-sheet in the proper longitude," but never a word as to what the proper longitude is.

FIG. 1.—A Crystal Palace. From "First on the Antarctic Continent." By C. E. Borchgrevink.

On pp. 270–71 we read, "We secured valuable photos. of Mounts Erebus and Terror, the former being in activity;" but will it be believed that these "valuable photos" are not reproduced? This is, we confess, the most staggering circumstance about the book. Dozens of excellent pictures are given which possess absolutely no scientific value, but the one which, of all others, the

geographer and geologist would like to examine has been kept back although it turned out a success.

The publication of his book will, we fear, tend to detract from the reputation which Mr. Borchgrevink has unquestionably merited by his organising power, his invincible perseverance and his successful completion of a considerable task. Had he been content to leave the the discussion of matters which he did not understand to the skilled members of his staff, and had he encouraged them to discuss and describe their observations, his expedition would have redounded to his credit in scientific circles, as well as amongst lovers of adventure. We believe that the extensive collections are being examined and described by specialists in the British Museum; and we hope that the magnetic and meteorological work will also be discussed by experts and published in detail. Some results in an unreduced form are given in the appendix, the most important being Mr. Louis Bernacchi's excellent summary of the meteorological and magnetic observations, which is somewhat fuller than that published previously in the *Geographical Journal.*

It is painful to us to be obliged to touch on the limitations of a strong and courageous explorer, but we cannot pass by without protest so striking an instance of the inability of an unscientific chief to appreciate the nature of the problems which his scientific subordinates are investigating or the results they obtain.

THE TOTAL ECLIPSE OF THE SUN, MAY 18, 1901.

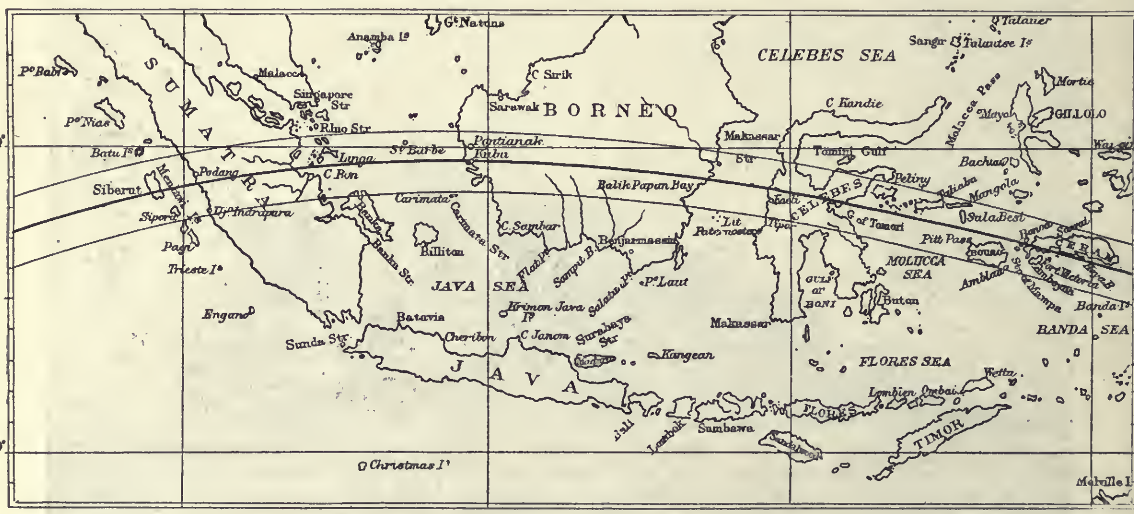
The approaching total eclipse of the sun is a notable one, not only on account of the unusually long duration of totality at the most favoured stations, but also because it occurs very near a time of minimum sun-spots. An exceptionally good opportunity of studying the corona at an important phase of the solar period is thus afforded, provided always that the sky is unclouded at the critical times.

The shadow strikes the earth a little to the south-west of Madagascar, traverses a north-easterly path across the Indian Ocean, passing over Mauritius and entering Sumatra near Padang, continues eastward across the southern part of Borneo, deviates to the south-east through the Celebes and the southern part of New Guinea, and leaves the earth in long. 156° 58′ E., lat. 12° 50′ S. (See accompanying map.)

While the weather prospects at most of the possible stations of observation are, unfortunately, not of the best, there is sufficient encouragement in the meteorological statistics to hope that records of the phenomena will be secured at at least one place.

In Mauritius, in the neighbourhood of the Royal Alfred Observatory, where the duration of totality is 3m. 35s., the chances of fine weather at eclipse time are very hopeful. Mr. Claxton, the director of the Observatory, states that on only two occasions since 1874 has the sky been overcast at 9 a.m. on May 18, on sixteen occasions it has been less than half covered, and on nine occasions practically cloudless (*Journal* of the Brit. Ast. Assoc., vol. xi. p. 121).

In the Malay Archipelago, where the maximum duration of totality on the central line is nearly 6½ minutes, the weather prospects are not quite so good. At Padang, on the west coast of Sumatra, which is one of the most accessible and otherwise most suitable stations, the percentage clearness during May is only 28, as against 50 per cent. for the Makassar Strait between Borneo and Celebes (NATURE, vol. lxiii. p. 163).



Part of the path of the moon's shadow during the total solar eclipse of May 17–18, 1901. Reproduce from the *Nautical Almanac Circular*, No. 18.

In these circumstances, it seems particularly desirable that the observers should be as widely distributed as possible, so as to diminish the risk of total failure to secure observations. This multiplication of stations, however, is rendered impracticable in this instance by the comparatively small number of astronomers at liberty to undertake the long voyage involved, and to some extent also by other causes, not among the least forcible being the undesirable presence of savage races at some places near the central line.

Arrangements have been made by the Joint Permanent Eclipse Committee of the Royal and Royal Astronomical Societies to attempt to secure observations at Padang and Mauritius. At the former station will be Mr. Newall and Mr. Dyson, who will be joined by Mr. Atkinson as a volunteer, and at the latter Mr. Maunder will work in conjunction with Mr. Claxton. While it is to be regretted that other British observers of experience do not find themselves in a position to join the expeditions, there is consolation in the fact that parties from other countries have arranged to make observations. We understand that Holland will be represented by an expedition under Dr. Nyland, of Utrecht, who will be

accompanied by W. H. Julius and W. H. Wilterdinck, of Leiden, and will probably make Padang his headquarters. Somewhere in the neighbourhood of Padang, also, the American astronomers, Prof. Barnard and Prof. Todd, together with a party from the Washington Observatory, and another party from the Lick Observatory, are expected to set up their instruments. Prof. Campbell has selected Mr. C. D. Perrine to take charge of the expedition from the Lick Observatory, and this observer will be accompanied by Mr. R. E. Curtiss, of the Observatory at Berkeley; the expenses of the expedition will be defrayed by the well-known liberal benefactor to science, Mr. W. H. Crocker, of San Francisco. The *Observatory* has further learned, through Father Cortie, that certain members of the Calcutta Jesuit Mission will also go to Padang to observe the eclipse.

The most direct route to Padang from Europe is by the Rotterdam-Lloyd line of steamers; a steamer leaving Southampton on April 9 and Marseilles on April 18 is due at Padang on May 12, and there is a return steamer on May 24, due at Marseilles on June 18. Return tickets at greatly reduced rates may be obtained through the British Astronomical Association.

As to the work to be undertaken, the great duration of totality emphatically demands that almost every effort should be directed towards the corona. Indeed, the study of the chromosphere and prominences during eclipses may well be considered to have reached a halting-place, so that in any case the study of these appendages would be considered of secondary importance. The great success which has attended the observation of recent eclipses has in some degree placed observation ahead of solar theory, and it is perhaps for this reason that most of the observations which, we understand, are to be undertaken are along familiar lines. To a certain extent this is, of course, inevitable, for it is always rightly regarded as a prime duty to record the phenomena as completely as possible.

Adequate provision is made for securing pictorial records of the corona. Some of these will be on a large scale to show the finer details of the lower reaches, and others on a smaller scale to depict the extensions seen with the naked eye. Messrs. Maunder and Claxton will utilise the photoheliograph of the Mauritius Observatory, giving pictures of the sun nearly 8 inches in diameter, and in addition will be provided with a 4-inch coronagraph fitted with a negative enlarging lens to give images 2 inches in diameter; the long extensions will be specially attacked with a 4-inch Dallmeyer R.R. lens of 32 inches focus.

At Padang, Mr. Dyson will erect the Thompson photoheliograph of 9 inches aperture, which was successfully employed by the Astronomer Royal in India and Portugal, the photographs being enlarged by a magnifier to a scale of 4 inches to the sun's diameter. The same observer will also take charge of a double camera with 4-inch lenses of relatively short focus to grasp the feeble rays of the longer streamers.

It is probable that Prof. Barnard's instrument will be the coronagraph of 61 feet focus, with which he obtained such admirable photographs of the prominences and inner corona last May. Prof. Todd will again employ his wholesale method of obtaining photographs with cameras in which the exposures are given and plates changed automatically. Coronagraphs of 33 feet 3 inches and 5-feet focus will form part of the equipment of the Jesuit Mission.

For the spectroscopic records, Mr. Maunder is provided with the 2-inch prismatic camera with which Mr. Evershed secured valuable photographs during the eclipse of 1898. With this type of instrument, the principles of which are now sufficiently familiar to render a description superfluous, the spectra of both corona and chromosphere are recorded in the most complete manner. A modified prismatic camera, in the form of an objective grating, will be employed by Mr. Newall in an attempt to photograph the coronal rings. Mr. Dyson will again employ the two slit spectroscopes belonging to Captain Hills, which were used in India and Portugal, one of them being specially adapted for the ultra-violet spectrum. Another important spectroscope will be the prismatic camera forming part of Dr. Nÿland's equipment; this consists of a 6-inch objective and two prisms of 45°, thus duplicating one of the instruments employed in the last two eclipses by Sir Norman Lockyer. The Jesuit Mission will investigate the spectroscopic phenomena with a Rowland concave grating of 36 inches focus, and a prismatic camera of 33 inches focus.

In the case of the slit spectroscopes and the objective grating, the long duration of totality will obviously be an immense advantage, and it is very desirable also that the experiment of giving very long exposures with the prismatic cameras should be made.

Among the more special inquiries, Mr. Newall will again attempt to investigate the rotation of the corona, and also to obtain photographs of the corona in polarised light. The first of these observations is a particularly delicate one, depending for its success on photographically recording the coronal spectrum with sufficient dispersion to exhibit the minute displacements of the bright lines produced by the rotation. The long duration of totality is especially favourable for this observation, but, on the other hand, there is evidence that at the time of sun-spot minimum the coronal lines are of but feeble intensity. Success is therefore by no means assured, but the slit spectroscope to be employed in the experiment is one of great efficiency and convenience, and the attempt is well worth making.

The study of the polarisation of the coronal light is also of some importance. The luminosity of the corona, apart from that due to the luminous gases of the inner corona, has been ascribed to the reflection of solar light by the small particles of which it is supposed to consist, and to the direct emission of light by such particles rendered incandescent by solar radiation. The bolometric observations of Prof. Langley's party at the last eclipse, however, led to the conclusion that the corona appears "neither to reflect much light from the sun, nor, chiefly by virtue of a high temperature, to give light of its own, but seems rather to be giving light in a manner not associated with high temperature" (NATURE, vol. lxiii. p. 67). On the other hand, Mr. Newall, during the same eclipse, found a marked polarisation of the coronal light, indicating that a considerable proportion of the light is reflected. The accumulation of additional data bearing on the origin of the light of the corona, therefore, seems very desirable.

The fact that a British man-of-war will be sent to Padang to render assistance to Messrs. Dyson and Newall is a sufficient guarantee that an adequate record of the general phenomena of the eclipse will be made.

A. FOWLER.

RED RAIN.

AN unusual, though it can scarcely be called a rare, meteorological phenomenon is reported from Italy, and has been made the subject of much highly coloured descriptive writing in the daily Press. The plain facts are thus given by Reuter's correspondent in Palermo in a telegram dated March 10:

"Since last night a dense lurid cloud has hung over this town. The sky appears of a sinister blood red hue, and a strong south wind is blowing. The drops of rain

that fall are like blood. The phenomenon, which is known by the name of blood rain, is attributed to dust from the Sahara Desert, carried here by the wind." And the Rome correspondent of the Agency on the same date says: "The phenomena reported from Sicily have also been observed in Southern Italy. The sky here has a yellow tint, and a violent sirocco is sweeping over the city. At Naples showers of sand have fallen, and the phenomenon of the Fata Morgana has been observed, the sky being of a deep red colour."

Later reports from Algiers describe the same occurrence in North Africa, and the explanation suggested is no doubt correct. It is simply a case of fine sand raised to a great height by one of the "dust devils" or whirlwinds of the Sahara, and carried by the movement of the upper air to a considerable distance before the particles, resisted in their fall by the friction of the air, have succeeded in reaching the ground. If rain happens to fall through such a cloud of suspended dust it naturally carries down a good deal of the material with it, and leaves red stains on drying up. If there is no rain, the fall of dry dust takes place all the same, and this effect is well known at sea in the trade-wind belt west of the Sahara.

It must be remembered that another kind of "blood rain," even more effective in appealing to the fears of the ignorant and superstitious, owes its alarming tint to the presence of minute organisms similar to those of red snow.

Dust rains of one kind or another are fairly frequent. Those of "sulphur" have been traced to the pollen blown abroad from conifers in the spring, and those of "ink," unhappily commoner in this country, to the catching up of smoke from manufacturing districts. Such a black rain, accompanied by intense darkness, fell over nearly 500 square miles in the north of Ireland in February 1898 during a spell of north-easterly wind, while in May 1899 a similar phenomenon was reported over an equal area of central and south-western England.

The precise atmospheric conditions necessary for the raising of dust or smoke into the upper parts of the atmosphere, and for the concentration and descent over special areas, is not yet fully understood; but the careful meteorological observations now made in many parts of Italy may be expected to throw some light on the general phenomenon when dealing with the recent occurrence.

DR. G. M. DAWSON, C.M.G., F.R.S.

GEOLOGICAL science, and Canada in particular, have suffered an irreparable loss in the death of George Mercer Dawson, C.M.G., LL.D., F.R.S., the director of the Geological Survey of that Dominion. He was born at Pictou, Nova Scotia, on August 1, 1849, and was the eldest surviving son of the late Sir John William Dawson, whose death was recorded in NATURE for November 23, 1899.

After studying at the McGill University in Montreal, he came to London and entered the Royal School of Mines in 1869. Here he gained the Duke of Cornwall's scholarship and the Edward Forbes and Murchison medals, thus passing with distinction as an Associate of the School. The training which he received in biology, as well as in geology and mining, was of essential service in his after career.

Having returned to Canada, he was in 1873 appointed geologist and botanist to the North American Boundary Commission, and two years later he joined the staff of the Geological Survey of Canada, becoming assistant director in 1883 and director in 1895.

For nearly thirty years he was thus actively engaged in field-work, gaining a broad and firm grasp of the leading features in the geology of Canada. If, as he himself remarked, much of his work was "of an exploratory character, and only occasionally, and then to a limited extent, precise or finished," it has been none the less important in advancing the science of geology and in furthering the development of the mineral resources of the Dominion. Far better equipped as a pioneer than was possible in the early days of geology, and keen in the examination of fresh ground, his enthusiasm was tempered only by the reluctance in leaving unsolved those problems which required further detailed study. In spite of constitutional infirmity, he possessed a marvellous amount of energy, while as a companion and leader he gained the confidence and affection of all who had the privilege of working with him.

His contributions to science, though mainly geological, were imbued with a general knowledge of natural history, and included observations on such subjects as seals, locusts and freshwater sponges. In geology he dealt at times with all the great formations, with volcanic rocks, with changes in the level of land, and with fluctuations of the great American lakes. In one of his earlier papers, communicated to the Geological Society of London, he described the glacial phenomena of the central regions of North America, and attributed the deposits of the great plain to the action of floating ice. In later papers he gave accounts of the remarkable evidences of glaciation in British Columbia, and of the shore-lines and terraces which extend from the present sea-level up to a height of more than 5000 feet. He then maintained the marine origin of the drifts of the western plains, but stated his opinion without dogmatism, or, as he puts it (in the British Association Handbook of Canada), "under all reserve and subject to further inquiry."

Many of his geological observations were embodied in his official reports, commencing with a general description of the Tertiary Lignite formation which overlaps the Cretaceous strata of the Red River—a report prepared for the British North American Boundary Commission. On the Geological Survey his work lay principally in British Columbia and the North-West Territory. The economic resources necessarily occupied much attention, and the mines and minerals, as well as the more purely scientific problems, were investigated as fully as possible in Vancouver Island, Queen Charlotte's Island, the Yukon territory, and in all parts of British Columbia. He contributed also to journals and transactions of societies in the United States as well as in Canada.

In later years his time was so largely occupied with administrative work, and in the preparation of his annual reports of the progress of the Geological Survey in Canada, that he had little time for recreation. The full value of his work has hardly as yet been appreciated, but there is no doubt that his name will stand in the forefront among Canadian geologists. It is already written permanently in Dawson city, of gold-bearing fame, in recognition of his able researches in that region.

In 1891 he was elected a Fellow of the Royal Society of London, and in the same year he was appointed one of H.M. Behring Sea Commissioners. During the inquiry connected with this Commission he made personal observations on the natural history of seals, and his services were officially recognised by his being made C.M.G. In 1891 also he was awarded the Bigsby Medal by the Council of the Geological Society of London, in appreciation of the value of his researches into the geological structure of Canada. In 1893 he was elected president of the Royal Society of Canada, and in 1896 he was chosen president of Section C at the Toronto meeting of the British Association.

He died on March 2 after a brief illness.

NOTES.

Two letters which have passed between Sir William Anson and Lord George Hamilton, with reference to the recent dismissals at Coopers Hill College, appeared in Wednesday's *Times*. Sir William Anson stated briefly the chief points upon which the request for an inquiry into the case is based. Accepting the decision that some change in the course of studies is necessary, it is urged that (1) the men affected by the proposed changes should have had an opportunity of a hearing when the president recast the course of studies, if only to see whether they would be willing to adapt themselves to the new conditions; (2) when the Board of Visitors considered, and in the main adopted, Colonel Ottley's recommendations, it does not seem to have been suggested to them that the teaching staff had not been consulted, or that they might have been consulted with advantage, or, at any rate, that the gentlemen whose dismissals were in contemplation had a right to be heard; (3) many persons eminent in science have expressed a strong opinion that the proposed dismissals will act injuriously on the scientific education of the country. In reply to Sir William Anson, Lord George Hamilton states that he has already taken steps to meet some of the complaints, and to put the teaching staff of the College upon a better footing. Upon his request the Board of Visitors have stated their readiness to meet to hear at once what the members of the teaching staff affected by the changes may wish to urge against them. In conclusion, Lord George Hamilton acknowledges that the channels of communication between those actually teaching and those in authority over the teachers—viz., the president and visitors—should be widened and quickened, and that a divergence of opinion such as has been revealed is detrimental, if not fatal, to harmonious co-operation. He adds, "I therefore propose to ask the Universities of Oxford, Cambridge and London to each nominate a visitor to be an addition to the present board. I shall ask the board, when so reconstituted, to appoint a committee, including the above, to inquire and report upon the working, discipline and constitution of the College, and the relations of the visitors, president and teaching staff."

THE Croonian Lecture of the Royal Society will be delivered on March 21 by Prof. C. Lloyd Morgan, F.R.S., on "Studies in Visual Sensation."

PROF. J. J. THOMSON, F.R.S., has been elected a member of the Athenæum Club under the provisions of the rule which empowers the annual election by the committee of nine persons of "distinguished eminence in science, literature, the arts, or for public services."

PROF. VON WETTSTEIN has been elected president of the Zoological-Botanical Society of Vienna.

THE Imperial Academy of Sciences of Vienna has inaugurated a botanical exploration of southern Brazil during the present year, under the leadership of Prof. von Wettstein and Prof. V. Schiffner.

WE learn from *Science* that the expedition sent by the U.S. Naval Observatory to observe the forthcoming solar eclipse was expected to leave San Francisco for Manila on February 16. From Manila it will be transported to Sumatra by a U.S. warship, and headquarters will be established at Padang about a month before the occurrence of the eclipse. The party includes Prof. Skinner, of the U.S. Naval Observatory, Prof. Barnard, of the Yerkes Observatory, Dr. Mitchell, of Columbia University, Dr. Humphreys, of the University of Virginia, and Mr. Jewell, of the Johns Hopkins University.

THE death is announced of Mr. John Hopwood Blake, F.G.S. Trained as an engineer under Brereton, he became an associate member of the Institution of Civil Engineers. In 1868 he joined the staff of the Geological Survey, and did much field-work in Somerset, in Norfolk and Suffolk, and latterly in Berkshire, Buckinghamshire and Oxfordshire. He was the author of memoirs on the geology of Yarmouth and Lowestoft, and of East Dereham, and had in preparation memoirs on the geology of Reading and on the water supply of Berkshire. Though slow as a worker and diffident in expressing his opinions, the work which he accomplished was performed with much enthusiasm and with the most painstaking care and precision. He died at Oxford on March 5, of angina pectoris, at the age of fifty-seven.

AT the Pan-American Medical Congress, which met recently at Havana, the board which has been engaged in the investigation of yellow fever, consisting of Drs. Reed, Carroll and Agràmonte, made a report. According to Press reports it was stated that two of the main conclusions were that the specific cause of the disease is unknown, and that it can be carried only by mosquitoes. The fever can be produced by a subcutaneous injection of blood from a patient who must have had the disease for not more than two days. Mosquitoes must also bite the patient during the first two days of his illness or they cannot transmit the disease. The board kept an infected mosquito for fifty-one days, when it was allowed to bite a person, who contracted the disease. The board differs from Dr. Finlay in that the latter holds that more than one kind of mosquito can convey yellow fever. The board says there is only one kind that can do so. Dr. Finlay also says that a mosquito can transmit the disease the fourth or fifth day after biting a patient, while the board says that twelve days must intervene. The board reported that non-immunes were allowed to sleep in infected clothing and bedding, but none contracted the disease. Dr. Wilde, of the Argentine Republic, proposed the creation of an international yellow fever board to study means of exterminating the disease.

THE Royal Irish Academy has this year taken a step, after prolonged consideration, which will, it is hoped, still further establish its position in Ireland, and in the world of science and letters in general. It has adopted the principle of the bye-laws of the Royal Society of London, respecting the mode of election of members; the council is now empowered to select a number of persons, not exceeding twelve, in each year, from the list of candidates for membership proposed, and to recommend these to the body of members for election. The members may, at the single annual meeting at which elections now take place, substitute the name of any candidate already proposed for that of any candidate selected by the council; but the number of candidates elected must not be greater than that fixed by the council for that particular year. Changes have been also made in the bye-laws so as to provide for the more frequent introduction of new blood into the council. The position of the Royal Irish Academy becomes at the same time defined in relation to the other great medium of scientific publication and intercourse in Dublin, the Royal Dublin Society. While the latter, by its objects and foundation, must be to a large extent a popular institution, performing its important public functions and scientific work by the support of an extensive body of members, the Royal Irish Academy is able, on the other hand, to maintain its membership as a distinction, and to attract to itself, by this circumstance, those who are mainly concerned with the furtherance of research. A large number of its members are naturally also members of the Royal Dublin Society, and thus enjoy the advantages offered by the publication-committees of both societies. With these two bodies in session, and with the *Irish Naturalist* as a medium for current notes, scientific work in Ireland need not wait long before receiving recognition and discussion.

A REPORT of a second lecture on wireless telegraphy, delivered by Prof. Braun at Strassburg, has been received. The first lecture was referred to in our issue of February 21 (p. 403), in which it was stated that we could not gather whether Prof. Braun had succeeded in obtaining a satisfactory separation of messages received at the same time from different sources. From the present lecture it appears that this difficulty has been overcome in Prof. Braun's system, as in Marconi's and Slaby's, by the use of syntony, which has been utilised, not only to separate different messages, but to augment the effect of the waves received in any particular message. No actual result of long distance trials is given in the report before us, but it is natural to suppose that Prof. Braun's system will succeed in this respect as have the other competing systems. It is interesting to note that all experimenters have been led to this method of separating messages; when wireless telegraphy first attracted attention it was suggested that messages might be confined to their particular destination either by the use of reflectors or by careful tuning of transmitter and receiver. Apparently only the second of these has proved practical; no doubt the long wave-length of the vibrations used have proved fatal to the satisfactory use of reflectors.

THE Board of Trade could not well have arrived at a more satisfactory decision in the conference which was held last week with reference to the proposal to reduce the charge for electric lighting by putting a maximum limit of 6*d.*, instead of 8*d.*, per unit in the provisional orders before Parliament this session. The proposal, which emanated from the Board of Trade, was supported by the London County Council but opposed by several influential electrical bodies, including the Institution of Electrical Engineers and the electrical section of the London Chamber of Commerce, on the ground that it would have the effect of discouraging electric lighting in small country places where the population was scattered. It was urged by Colonel Crompton, on behalf of the Institution of Electrical Engineers, that the advantages to be gained by reducing the maximum in every district would be outweighed by the disadvantage of preventing the spread of electricity all over the country. This is, however, no reason why the dwellers in towns should pay highly that their brethren in the country may enjoy the benefit of electric light, and the obvious solution is that the maximum price should be regulated by the circumstances of the case. This is the solution adopted by the Board; they would fix, said Sir Courtenay Boyle, a normal maximum of 7*d.* a unit, but in the populous districts they would endeavour to make this 6*d.*; in special cases an 8*d.* maximum would be allowed if the undertakers were able to show sufficient cause.

SEVERAL correspondents have written to us with reference to falls of snow or ice crystals such as have been mentioned already (pp. 420, 441). Prof. G. H. Bryan states that a fall of snow stars occurred at Edgbaston, Birmingham, on January 6, and a similar fall, in which the stars were somewhat larger, happened at Bangor on February 15. "In the latter case," he adds, "the crystals which fell in the morning were not sufficient in number to form a coating on the ground, but many of them remained unmelted during the afternoon in shady corners. A few days later isolated stars were again falling, and this time the rays were larger and more feathery." Dr. Abbot noticed a fall of snow crystals at Tunbridge Wells in February, and in connection with the subject he asks whether such crystals should be considered as (1) skeleton crystals, (2) twins, or (3) aggregates of very small hexagons. He remarks:—"What seems to me the most interesting question is the regularity of the angles and distances of the secondary branches; and if we are dealing with skeleton forms, are not ice crystals unique in having these?" Another correspondent says that during a fall of snow crystals at Newcastle at the end of January or beginning of February last some of the crystals were about a quarter of an inch in diameter, and the outline was nearly circular.

SIR COURTENAY BOYLE objects, in the March number of *Macmillan's Magazine*, to many words in common use in science. His objections are partly etymological and partly to the vagueness of connotation of the words. Pliocene, miocene and phonolite are incorrectly formed; and the first two, together with palæozoic, mesozoic, kainozoic, jurassic and triassic are condemned because they are purely relative terms. Electron is objected to because there is sometimes a doubt whether it signifies a minute corpuscle having an electric charge or an electric charge without the corpuscle. Kion and autokion are suggested as preferable to the unsatisfactory words motor and the hybrid automotor.

THE U.S. *Monthly Weather Review* for November, 1900 (the last received) contains an interesting note of lightning from a cloudless sky, by Mr. C. E. Ashcraft, jun., of the Weather Bureau, Dominica. The phenomenon seems to be regarded in the States as one of rare occurrence, but in the West Indies it is frequently observed. The appearance of the flashes is that of sheet-lightning, and they do not seem to be confined to any particular quarter of the sky. The author considers that the theory of the exchange of electricities between vertical currents of air is a plausible explanation, as the phenomenon has always been observed in the evening, usually between seven and nine o'clock, at which time the colder currents of air are descending and setting up a vertical circulation, with steep gradients, and it is also at this time that the maximum electrification of the air occurs. Sometimes the sky is not absolutely clear, a few clouds hanging over the mountains to the east of the station, but the lightning will be seen far out to sea, where not the least vestige of cloud is visible. The flashes have been observed more frequently during the hurricane season. The phenomenon does not appear to be peculiar to the region of Dominica alone, but is said to have been observed in other parts of the tropics.

A NOVEL marine torch, in which acetylene gas is the illuminant, and of special design to ensure immediate ignition on being plunged into water, is described in *Fielden's Magazine*. The torch, it is stated, "simply consists of a plain cylinder of metal, sizes varying from 3 to 8 inches in diameter and from 1 to 5 feet in length. The cylinder, which is sealed at each end, contains in a wire basket a quantity of carbide of calcium and it also contains an air chamber to ensure sufficient buoyancy. At the head of the cylinder a number of burners is arranged adjacent to which is a small chamber containing calcium phosphide, which on contact with water generates phosphuretted hydrogen, ignites and also lights up the acetylene as it issues." The torch, which has no mechanism, is automatic throughout, the only precaution necessary before plunging into water being the removal of a protecting strip of metal by pulling a ring. The illuminating power of the torch can be gathered from the fact that a six-inch torch burns from an hour to an hour and a half with a candle-power of 2000 and a flame 12 inches high, and other torches which are rechargeable will burn from half an hour to ten hours according to size.

A FEW interesting instances of the application of physical instruments to the study of disease are given by Mr. Paget in a short review of the chief events in medicine and surgery between 1800 and 1850, in the *Middlesex Hospital Journal*. The chief influences which caused the great advance in the last ten years of that half century are stated by him to have been, first, the constant and general use of the microscope, both in physiology and pathology. Men left off speaking of tumours as "strange distempered masses"; they set to work to learn their minute

structure, and to interpret from it the clinical facts of each case. Next, the study of fevers, especially Sir William Jenner's observations on the essential difference between typhus and typhoid; and the improved treatment of fevers that was taught and practised by Graves of Dublin; he who said that he desired for an epitaph these words, "He fed fevers." Then, the invention of the ophthalmoscope by Helmholtz and the laryngoscope by Garcia, and the rise of special departments in hospital teaching, and of special work in practice. Next, the exact use of electricity in the diagnosis and treatment of nerve diseases, especially the work of Duchenne. The use of the thermometer followed, not invented all at once like the stethoscope, but very slowly established by years of work and millions of observations, especially the work of Wunderlich. Then the abolition of the old rough-and-ready methods of medical treatment, of useless bleeding and purging and low diet, and shameful abuse of mercury; and the knowledge of the selective action of drugs, especially the physiological study of such drugs as strychnine, curari, atropin and digitalis. Last of all, and best of all, the discovery of anæsthetics.

THE report of the Decimal Association records the progress made in the provision of instruction in the metric system of weights and measures, and the adoption of the system. By an article introduced into the code of elementary schools in 1900, instruction in the principles of the metric system, and in the advantages to be gained from uniformity in the method of forming multiples and submultiples of the unit, is made obligatory in the upper standards. Negotiations are in progress for bringing about a conference in Paris of official delegates and others, representing Great Britain, the United States and Russia, in favour of the adoption of the metric weights and measures in those countries. If this conference be held it will doubtless have important results. Active steps continue to be taken in the United States, and a bill for the introduction of the metric weights and measures in the State Departments is now before congress at Washington, and has been reported on favourably by the committee on coinage, weights and measures. The growth of public opinion in this country in favour of the metric weights and measures has attracted much attention in the United States, and has given an impetus to the movement there. In Canada, the Government are said to be seriously considering the adoption of the metric weights and measures, and several encouraging communications have been received by the Decimal Association from residents in that country. In Russia there is a growing disposition on the part of the Government to adopt the metric system, and there are good grounds for believing that an important step will be taken in that country shortly. In July last a report was issued by the Foreign Office which contained the replies of Her late Majesty's representatives in Europe to a circular addressed to them by the Marquis of Salisbury, asking for information as to the actual experience of nations which had adopted the metric system. The replies showed that in all cases the change was made without much difficulty, that there had never been any desire to return to the former system in use, and that the adoption of the metric system had assisted in the development of the trade of the countries which had adopted it. The second part of this report has just been published, and bears out these conclusions.

A SIMPLE elementary exposition of the principles of thermodynamics treated by means of the familiar p, v diagram is given by Mr. Robert H. Thurston in the *Journal* of the Franklin Institute, under the title "Elementary Graphics and Geometry of Thermodynamics."

IN the *Rendiconto* of the Naples Academy (January), Prof. Domenico de Francesco discusses certain problems in the dynamics of pseudospherical space. In a previous memoir the author gave an investigation of "motion under no forces" for such space, and he here interprets for the same kind of space the differential equations which in ordinary space represent motion about a fixed point under arbitrary forces.

IN the ordinary theory of elasticity it is proved that when a body occupying a simply connected region is not acted on by either surface tractions or bodily forces the strain vanishes at every point of the interior. Nevertheless, bodies may exist in which internal tensions act; for example, we may imagine a split ring the ends of which do not meet, and suppose these ends brought into contact and welded together. In the *Atti dei Lincei*, x. 3, Signor G. Weingarten points out that in all such cases surfaces must exist at which the displacements are discontinuous, and he discusses the properties of such surfaces. The subject is an interesting one, but the paper is only a short note.

IN the *Journal* of the Franklin Institute, Mr. John Price Jackson discusses the use of electricity for coal mining. Electricity may be economically used for lighting, hoisting purposes, pumping, cutting, drilling, running fans, operating breakers or washers, propelling bucket or belt-lifts, driving repair shop apparatus, &c. The question as to whether any or all of these applications shall be used is dependent directly upon local conditions. If a system of mines owned by one company are supplied from a central power-house, it is clearly possible to entirely do without local steam plants at the individual mines. Such an arrangement has several advantages in the matter of economy of fuel, the very great economy in repairs and a still further economy in working speed efficiency.

Science Abstracts always contains statements of results of interest to all students of science, as well as descriptions of work of special value to those engaged in work in physics and electrical engineering. To the latter the periodical is invaluable, and it should find a permanent place in the library of every Technical Institute and School of Science, as well as in educational institutions of higher rank. Many subjects are described in the abstracts, which are concise, well arranged, and of real importance to workers in all branches of physical science. There is no better way of creating an interest in scientific work and arousing a spirit of emulation than by making students familiar with the progress of scientific knowledge.

THE *Irish Naturalist* for March contains an excellent account of the natural history of that comparatively rare visitor to the British coasts, the grey phalarope, by Mr. C. J. Patten.

IN the *Entomologist* for March, Mr. W. L. Distant describes two new species from West Africa of that remarkable genus of Heteroptera known as Pephricus, the members of which so curiously resemble crumpled and broken leaves. The genus is of especial interesting as being one of the first in which "mimicry" was noticed, Sparman, who discovered the type species in 1775, mentioning his surprise on observing signs of active life in what he had taken for a dead leaf gnawed by caterpillars.

A HIGHLY suggestive and thoughtful paper on the question of the arboreal ancestry of marsupials and the mutual relations of the mammalian subclasses appears in the February number of the *American Naturalist*, by Mr. B. A. Bensley, who is now in this country studying marsupial ancestry. Taking as a text Dollo's view that marsupials were originally arboreal, that, on account of their foot-structure, they could not have been ancestors of placentals, and that they themselves are degenerate placentals, Mr. Bensley contrasts this with Huxley's scheme of mammalian evolution. According to the latter the Prototheria, which became specialised into the modern monotremes, gave

rise to the Metatheria, whose specialised representatives are the marsupials; while the Eutheria, specialised into modern placentals, are likewise an offshoot from the Metatheria. This phylogeny, thinks the author, is the most probable of all. It is urged that the imperfect placenta of the bandicoots, instead of being, as considered by Mr. Hill, vestigial, may be an instance of parallelism, and that in marsupials generally the allantois failed to form a placental connection. Owing to the antiquity of both placentals and marsupials, the arboreal character of the feet of the modern forms of the latter is of little importance. Further, it is considered that too much importance has been assigned to the characters distinguishing monotremes from other mammals; fœtal marsupials showing a monotreme type of coracoid, while it is probable that in the long run it will be found impossible to maintain the essential dissimilarity between the milk-glands of monotremes and those of other mammals.

ANOTHER paper in the same issue of the *American Naturalist*, by Mr. A. E. Ortman, deals with the subject of the geographical distribution of animals and plants, its title being the "Theories of the Origin of the Antarctic Faunas and Floras." Sir Joseph Hooker first, and the late Dr. L. Rütimeyer second, are credited with being the pioneers of the idea of the essential unity of the southern faunas. Rütimeyer, indeed, distinctly states that "we should take a part of the present faunas of South America, South Africa and Australia for remnants of an old fauna that spread over a large extent of the Antarctic continent, and that this Antarctic continent was the centre of origin of a peculiar Antarctic fauna." Here it may be appropriately mentioned that Dr. Stejneger, in a paper in the same journal, feeling, like many other writers, the urgent want of a word denoting both fauna and flora collectively, proposes the term "Biota" to fill the gap. If this were adopted, he adds, "*biotic* would then signify 'pertaining to or treating of a biota,' as, a biotic publication, a biotic region."

IN continuation of his earlier researches, Dr. Carl Sapper contributes a paper on the ethnography of southern Central America to the February number of *Petermann's Mitteilungen*. The paper gives an account of the languages of the region, with a map showing their distribution in 1899, and a comparative review of the civilisations of the different Indian tribes.

DR. EMIL SCHLAGINTWEIT returns to the question of the name of the highest mountain in the world in an article in the current number of *Petermann's Mitteilungen*. After discussing specially the Tibetan names Chomo Kankar and Tsering chenga, strictly Jomo gangs dkar and Thse ring mched lnga, Dr. Schlagintweit reasserts his former decision in favour of the name *Gaurisankar-Everest*.

THE *Verhandlungen* of the Berlin *Gesellschaft für Erdkunde* contains a paper on the geological history of the North German plain, by Prof. Wahnschaffe. An excellent summary is given of recent additions to our knowledge of the glacial phenomena of this region, especially those derived from deep borings. The *Zeitschrift* of the same society contains two important papers, one on the country and people of north-eastern Tibet, by Dr. K. Futterer, and a discussion of Dr. S. Passarge's observations of atmospheric pressure and temperature in the Lake Ngami region as applied to the determination of heights, by Herr G. von Elsner.

THE report of the Danish Meteorological Institute on the ice of the Arctic seas during 1900 has just been issued. With the support of the Seventh International Geographical Congress the Institute has been enabled to make this report fuller than in former years; not only is full information given from the Atlantic-Arctic waters, but a number of observations from the Bering and Beaufort Seas. The general features during the season were—great masses of ice in the north-west part of Barents Sea and round Spitsbergen, considerable masses of ice in the Kara Sea, less ice than in a normal year between Franz Josef Land and Novaya Zemlya and under the east coast of Greenland, normal conditions off south-west Greenland, and particularly favourable conditions off Labrador and in Baffin's Bay.

In the third part of his "Geology of the Boston Basin," Mr. W. O. Crosby deals with "The Blue Hills Complex" (*Occasional Papers*, Boston Soc. Nat. Hist., 1900). This complex is the area of granitic rocks and associated Cambrian strata in eastern Massachusetts, which includes the Blue Hills and the country eastwards to Quincy and the northern parts of Braintree and Weymouth. In this region is the famous quarry which yielded *Paradoxides Harlani* of the Middle Cambrian, but the Lower Cambrian with *Olenellus* is likewise represented. No recognisable trace of the floor upon which the Cambrian strata were deposited has been discovered, but that Upper Cambrian or Potsdam strata exist, or formerly existed, in the region is evidenced by fossiliferous pebbles in the Carboniferous rocks, which, together with drift deposits, occupy much of the ground. The Cambrian strata were strongly folded and invaded by great bodies of igneous rocks not later than Devonian times. All these rocks and the effects of metamorphism are fully described and illustrated. The author also discusses the relations of the Blue Hills complex to the peneplains of eastern Massachusetts, and to the Glacial phenomena of the area. The palæontology of the Cambrian strata is dealt with by Mr. A. W. Grabau, and the leading fossils are figured.

A NEW part of the revised second edition of Prof. Arnold Lang's "Lehrbuch der vergleichenden Anatomie der wirbellosen Thiere," dealing with the Protozoa, has been received from the publisher, Mr. Gustav Fischer, Jena. The book has been completely revised and partly rewritten.

THE *Monist* for January contains the translation of an address, by Prof. Ludwig Boltzmann, on "The Recent Development of Method in Theoretical Physics." This address was originally delivered at the congress of the Gesellschaft deutscher Naturforscher und Aerzte in Munich in September 1899.

A NEW meteorological journal has been established under the title *Climate*, with Mr. N. A. Demchinsky as editor. The periodical will appear twice a month, and all its contents will be in four languages—Russian, German, French and English. The chief object is to apply to weather prediction Mr. Demchinsky's theory that the moon is the chief factor in meteorological changes.

A LIST of the birds of the Bristol district is given in the volume of *Proceedings* of the Bristol Naturalists' Society (vol. ix. part 2) just published. Other papers are on a Rhætic section at Redland—a suburb of Bristol, by Mr. W. H. Wickes, with additional observations on the beds, by Mr. J. Parsons, and on Triassic deposits at Emborough, by Prof. Lloyd Morgan, F.R.S., and Mr. S. H. Reynolds.

THE second part of the report on a bathymetrical survey of the fresh-water lochs of Scotland, by Sir John Murray, K.C.B., F.R.S., and the late Mr. Fred P. Pullar, appears in the March number of the *Geographical Journal*. An account of the first part of the survey was given in NATURE of May 17, 1900 (vol. lxii. p. 65). The second part treats of the remaining lochs of the drainage basin of the Forth, viz., Loch Chon, with Lochan Dubh, Loch Ard, and Lake of Mentieth in Perthshire, and Loch Leven in Kinross-shire. The same number of the *Journal* contains a report of the special meeting held to commemorate the progress of geographical discovery during the Victorian reign.

THE general appendix to the annual report of the Smithsonian Institution for 1898, which has just been received, consists of

reprints and translations of thirty-six papers of wide scientific interest. Many branches of science are represented by the papers, and the whole collection forms a most interesting and valuable survey of subjects prominently before the scientific world in 1898. Limitations of space prevent us from giving a list of the papers reprinted from various reviews and scientific periodicals, but we are glad to direct attention to the following translations:—Recent progress accomplished by aid of photography in the study of the lunar surface, from a paper by MM. Loewy and Puiseux; the Le Sage theory of gravitation, translated from a paper by M. Prevost, with introductory note by Dr. S. P. Langley; the extreme infra-red radiations, by Dr. C. E. Guillaume; the perception of light and colour, by M. G. Lechalas; progress in colour photography, by M. G. H. Niewenglowski; oceanography, by M. J. Thoulet; the relation of plant physiology to the other sciences, by Dr. Julius Wiesner; *Pithecanthropus erectus*—a form from the ancestral stock of mankind, by Dr. E. Dubois; our present knowledge of the origin of man, by Prof. E. Haeckel; the laws of orientation among animals, by Captain G. Reynaud; the theory of energy and the living world—the physiology of alimentation, by M. A. Dastre; a sketch of Babylonian society, by Herr F. E. Peiser; the excavations of Carthage, by M. P. Berger; the origin of African civilisations, by Dr. L. Frobenius; dogs and savages, by Dr. B. Langkavel; the life and works of Brown-Séquard, by M. Berthelot. It will be seen from this list that the volume contains no less than sixteen translations of papers on important subjects. By publishing these translations, with the reprints, the Smithsonian Institution records the progress of scientific thought in a most serviceable way, and enlarges the outlook of men of science who do not read German and French with facility.

THE discovery of the organo-metallic compounds nearly half a century ago, by Frankland, opened up a wide field of organic synthesis, which has for some time been regarded as exhausted. It has, however, been recently shown by M. Grignard that many syntheses which are effected only with difficulty with the zinc alkyls can be carried out with great ease with magnesium compounds. In the current number of the *Comptes rendus* M. Grignard gives a *résumé* of his work in this direction, together with a theoretical study of the reaction. By the action of magnesium upon an alkyl iodide the compound RMgI is first formed, and this condenses readily with aldehydes and ketones, without there being any necessity to isolate the organo-metallic compound, giving ultimately secondary or tertiary alcohols, the yields being as high as 50 per cent.

THE additions to the Zoological Society's Gardens during the past week include a Pardine Genet (*Genetta pardina*) from West Africa, presented by Lady Moor; a Common Otter (*Lutra vulgaris*), British, presented by Mr. W. Radcliffe Saunders; a Yak (*Poephagus grunniens*) from Tibet, presented by Mr. A. E. Pitt-Rivers; a Blue Whistling Thrush (*Myiophoneus coeruleus*) from the Himalayas, a Jerdon's Green Bulbul (*Chloropsis jerdoni*), a Black-crested Yellow Bulbul (*Otocampsa flaviventris*), two Blyth's Hill Partridges (*Arboricula rufigularis*), an Indian Green Barbet (*Thereiceryx zeylonicus*) from India, a Great Barbet (*Megalaema virens*) from China, presented by Mr. E. W. Harper; a Grey-backed White-eye (*Zosterops dorsalis*) from Australia, presented by Mr. D. Seth-Smith; a Buzzard (*Buteo vulgaris*), European, presented by Mr. J. A. Harvie Brown; a Black Kite (*Milvus migrans*), European, presented by Mr. H. Wreford; a Red Kangaroo (*Macropus rufus*) from Australia, two Striated Jay Thrushes (*Grammatoptila striata*) from the Himalayas, two Rufous-chinned Laughing Thrushes (*Ianthocincla rufigularis*), a Rat Snake (*Zamenis mucosus*) from India, deposited; a Black-faced Kangaroo (*Macropus melanops*) from Tasmania, a Barraband's Parrakeet (*Polytelis barrabandi*) from Australia, purchased.

OUR ASTRONOMICAL COLUMN.

NOVA PERSEI.—The position of the star, as given by the meridian circle at Greenwich, is

$$\left.\begin{array}{l} \text{R.A.} = 3^{\text{h}}\ 24^{\text{m}}\ 28^{\text{s}}\cdot 21 \\ \text{Decl.} = +43^\circ\ 33'\ 54''\cdot 8 \end{array}\right\} (1901).$$

During the fortnight since its discovery the star has undergone a remarkable series of changes both in brightness and spectrum.

Variation in Brightness.

	Mag.		Mag.		Mag.
Feb. 22	2·7	Feb 28	2·1	March 6	2·9
23	0·10	March 1	2·2	7	3·0
24	0·65	2	2·3	8	3·2
25	1·0	3	2·4	9	3·5
26	1·1	4	2·6	10	3·7
27	1·5–2·1	5	2·7	11	3·9

In the current issue of *Comptes rendus* (vol. cxxxii. pp. 535–538) M. H. Deslandres describes his observations on the spectrum made with the spectroscope designed for line of sight measures at the Meudon Observatory. The photograph of the star's spectrum was obtained alongside a comparison showing the lines of iron, calcium, hydrogen, helium and air.

After noting the great breadth of the bright lines, he states that the middle of each band is displaced *towards the red* with respect to the terrestrial spectrum. The spectrum is similar to Nova Aurigæ, but the lines are broader. He then draws attention to the minute structure of the $H\beta$ (F) line of hydrogen, which shows *three* maxima of brightness, the more refrangible component being the most intense. The other lines show similar structure, but not so clearly.

On the other hand, the calcium lines at H and K each show a fine, clear, dark line, the only sharp lines in the spectrum; both are displaced slightly towards the red M. Deslandres discusses the two explanations of the width of the lines, that of Doppler-Fizeau ascribing the appearance to motion, the other, suggested by the experiments of Humphrey and Mohler and Wilsing, indicating the cause to be the great pressure to which the gases are probably subjected. He concludes by ascribing the group of lines immediately less refrangible then $H\beta$ to magnesium and asterium, but these have been traced by other observers to the most prominent enhanced lines of iron.

CO-OPERATION IN OBSERVING VARIABLE STARS.—*Circular* 53 of the Harvard College Observatory consists of an outline plan drawn up by the Director, Prof. E. C. Pickering, for enabling a systematic investigation of variable stars to be made by the cooperation of observers in various localities. This has been induced by the fact that the number of long-period variables is now so great that many of them are neglected.

In the case of variables of small range the difficulty is not so great, as the variation is in most cases regular, but many of the variables of long period appear to change irregularly, and continuous observations are required until the nature of the changes are known. Moreover, the range is, in many cases, so great that the errors of observation are not sufficient to affect seriously the form of the curve.

It is recommended that in the vicinity of each variable a series of about twelve comparison stars be selected, the brightest being slightly brighter than the variable at maximum, and the faintest fainter than the variable at minimum. The intermediate ones should gradually decrease in brightness with about half-a-magnitude differences.

The actual magnitudes of all such stars brighter than the *seventh* magnitude can be supplied from the meridian photometer records, and means are now being adopted for furnishing on a uniform scale the brightness of the faintest stars likely to be visible in any telescope. At least one observation of each star should be made every month.

For searching out comparison stars the excellent charts of Father Hagen are recommended for stars fainter than the ninth magnitude. For brighter ones copies have been made of the Bonn Durchmusterung charts, giving 3° square about each variable, and these will be supplied to experienced observers willing to co-operate in the work. A list of seventy-three variables for which these charts will soon be ready is furnished.

DIMENSIONS OF THE SATURNIAN SYSTEM.—Prof. T. J. J. See has recently completed a long series of measures of the

various planetary systems with the 26-inch refractor of the United States Naval Observatory at Washington. In the *Astronomische Nachrichten* (Bd. 154, Nos. 3686–7) he gives the details and results of the investigations of Saturn, including measures of the planet, rings, and the satellite Titan. He attributes much of the consistency of the values determined to the use of various colour screens placed between the eye and the telescope, which reduces or eliminates entirely the secondary spectrum produced by the objective, thereby enabling a much more sharply defined disc to be obtained.

In addition to his own recent measures, the author also brings together previous work on the subject from 1659. The following is a summary of the new determinations:—

	″	km.
External diameter of the outer ring ...	=40·304	278,768
Internal diameter of the outer ring, *or* External diameter of Cassini's division	=34·787	240,610
Diameter of the centre of Encke's division	=37·777	261,290
Width of Encke's division	= 0·107	740
Total width of the outer ring	= 2·758	19,076
Width of the outer part of the outer ring	= 1·237	8,556
Width of the inner part of the outer ring	= 1·414	9,780
Width of Cassini's division	= 0·418	2,891
External diameter of central ring ...	=33·951	234,827
Internal diameter of central ring, *or* External diameter of dusky ring ...	=25·952	179,501
Width of central ring	= 4·000	27,667
Internal diameter of dusky ring ...	=20·582	142,359
Black space between Saturn's globe and dusky ring	= 1·567	10,838
Equatorial diameter of Saturn	=17·448	120,682
Assumed oblateness of Saturn (H. Struve)	= 0·1013	
Polar diameter with this oblateness ...	=15·681	108,457
Assumed mass of Saturn (Bessel) ...	= 1:3501·6	
Resulting mean density of planet ...	= 0·1234=0·679 that of water.	
Diameter of the satellite Titan ...	= 0·487	3,368

HYDROGEN IN AIR.

IN a recent number of the *Annales de Chimie et de Physique* (January, 1901), M. Armand Gautier, professor of chemistry at the École de Médicine, Paris, gives a connected account of his researches on the combustible gases of the atmosphere. These researches have occupied some years, they have been carried out with extraordinary care and completeness, and they have yielded results of very great interest both in regard to their main object and also in relation to incidental scientific questions.

The most striking fact elicited by M. Gautier is that pure air contains free hydrogen as a normal constituent to the extent of about two volumes in 10,000. This conclusion, taken in conjunction with the recent experiments of Profs. Liveing and Dewar (NATURE, December 20, 1900, p. 189), in which they record the isolation of a fraction of air containing 43 per cent. of hydrogen, which they actually exploded, seems to admit of no doubt.

Analytical Methods.—M. Gautier set himself to determine the character and amount of combustible gases in the atmosphere by aspirating a large volume of air through a train of absorbents. Nothing could be more obvious and simple in principle than such a method; the difficulty of making it available for determining with any degree of certainty the character and quantity of very small amounts of combustible gases will, however, be thoroughly appreciated by chemists.

The first part of M. Gautier's memoir is devoted to a description of the preliminary work which was necessary for the selection and proper use of the absorbents. Beginning with carbon dioxide, he confirmed the previous observation of Boussingault and Eliot and Storer that carbon dioxide is very difficult to absorb from a large admixture of other gases. After circulating 90 litres of ordinary air during forty-eight hours through a tube 80 centimetres long and containing glass beads moistened with caustic potash solution of density 1·3, it was found that 10·7 c.c. per million of CO_2 remained unabsorbed. A satisfactory absorbent in respect both to rapidity and completeness was found in barium hydrate, either dissolved or simply moistened with water. This substance would, of course, also absorb other acid gases, such as H_2S, SO_2 and NO_2.

The desiccation of air by sulphuric acid was also shown to be incomplete; a satisfactory agent was found in phosphoric oxide previously heated with oxygen at 260° C. to get rid of lower oxides.

For the absorption of minute quantities of carbon monoxide the ordinary reagents are ineffective and a new one was found in iodine pentoxide. Air containing 1/100,000th of the gas loses it completely and at once when passed over the pentoxide heated to 70° C. Carbon dioxide, oxygen, nitrogen, hydrogen, marsh gas have no action on the oxide at that temperature, and other more strongly reducing gases, such as alcohol vapour and benzene when much diluted are also without action. When carbon monoxide acts upon iodine pentoxide, iodine and carbon dioxide are produced; the iodine is absorbed by a tube containing finely divided copper and the carbon dioxide by barium hydrate. The estimation of hydrogen and hydrocarbons is next dealt with. When a mixture of 50 c.c. of hydrogen with 235 litres of pure air was passed over heated oxide of copper the hydrogen was entirely burnt provided that a tube of 70 centimetres was employed. With a tube of 30 centimetres, only 70 per cent. of the hydrogen was burnt. When using shorter tubes in subsequent experiments the weight of water obtained had to be multiplied by a factor in order to give the effect of an "infinite" tube of copper oxide.

When diluted marsh gas is passed over heated copper oxide there is neither complete combustion nor equivalent combustion of the carbon and hydrogen, and here also the use of factors is necessary. The hydrogen burns in greater proportion than the carbon. With a diluted mixture of marsh gas and hydrogen it was found that the presence of the hydrogen facilitated the combustion of the hydrogen of the marsh gas but retarded that of the carbon. Admixture of the copper oxide with spongy platinum or with other metallic oxides did not improve the efficiency. It was found that the copper oxide, after continued heating to redness, gradually lost its power of oxidising, and after 1500 hours it was without effect upon hydrocarbons, and it only partially oxidised free hydrogen.

For a detailed description and drawing of the apparatus the original memoir must be consulted. The air was filtered from suspended impurities by filtration through glass wool, its carbon dioxide was then absorbed—and in this connection the author devised a special form of absorption tube which he strongly recommends—water was then absorbed and the air entered the combustion tube. The combustion tube was heated in a furnace of special construction, in which great uniformity of temperature could be maintained from end to end. Water and carbon dioxide formed by combustion were then absorbed, and the apparatus terminated in an aspirator, a "decanteur" and a meter. There were in all twenty-eight pieces in the train; they were connected together by clamped india-rubber joints made from purified tubing, which experiment showed to be proof against diffusion.

The Air of Paris.—Beginning first with towns, M. Gautier examined the air in the region of the École de Médicine. The average ratio of carbon and hydrogen found corresponded pretty nearly to CH_4, but there was evidence at times of some more highly carburetted hydrocarbon being present, at others of free hydrogen.

There was no evidence of hydrocarbons of the ethylene or acetylene series being present.

The quantity of carbon monoxide found was extremely small, it averaged 2·11 volumes per million, but this included one very abnormally high instance. Neglecting this one instance the average of ·56 volume per million was obtained. The quantity of carbon monoxide varied in different places; it increased in densely populated places. In a small room at the laboratory heated by an old-fashioned faïence stove and illuminated for several hours by three gas jets 12·3 volumes were found. On the whole the quantity of CO and unsaturated hydrocarbons in town air may be said to be insignificant.

The Air of Forests.—The next experiments related to the air of forests, and the station fixed upon was a clearance in the middle of a wood at Lainville, 70 kilometres from Paris.

Here the proportion of carbon to hydrogen pointed distinctly to the presence of free hydrogen along with marsh gas. It did not seem probable that the hydrogen came directly from living vegetation, but it was possible that it might arise from decomposition going on in the soil, and it was therefore decided to make analyses in localities where this possible source would be removed to a large extent.

Mountain Air.—With the object just referred to, the next station selected was in the Pyrenees on the Pic Canigou, a barren mountain 2785 metres in height. The transport of the apparatus to this remote station required six porters and mules, and M. Gautier with his *préparateur* and one guide were left to make the best of a rock cabin amidst the snow, fires being suppressed in order to avoid contamination of the atmosphere.

Under these cheerless conditions a series of determinations was made which amply realised the anticipation that in the absence of vegetation and soil the proportion of marsh gas would diminish. The quantity found was 2·19 volumes per 100,000 as against 11·3 for the air of woods and 22·6 for the air of Paris.

The quantity of free hydrogen reached 17 parts per 100,000.

Sea Air.—M. Gautier now decided to get rid of vegetation altogether by going out to sea, and took up his station during the autumn equinox at the iron lighthouse of the Roches-Douvres, 40 kilometres from the coast of Brittany. He arrived after a series of north-west gales, and was, he says, altogether *très favorisé par les circonstances.* Analysis showed a fall in the proportion of carbon to 1/33 of what it was in mountain air, that is, to an almost negligible quantity. There was an increase in the amount of free hydrogen to 19·5 vols. per 100,000. It appears, therefore, that the air over the sea and at very high altitudes is nearly free from hydrocarbons, and that it contains two vols. in 10,000 of free hydrogen, a proportion, it will be observed, about two-thirds of that of the atmospheric carbonic acid.

Source of the Gases.—In the concluding section of his memoir, M. Gautier discusses in more detail the nature of the accessory combustible gases in the air and the origin of atmospheric hydrogen. He concludes that, subject to variations, the combustible gases of Paris air may be set down as follows, in volumes per 100,000:—Free hydrogen 19·4, methane 12·1, benzene vapour or analogous compounds 1·7, carbon monoxide and traces of olefines and acetylenes ·2.

It remains now only to show that the presence of hydrocarbons in air is in accordance with established geological facts, and that it is connected with the occurrence of the larger quantities of free hydrogen. M. Gautier points out that methane is exhaled from many soils, that it is the chief constituent of fire-damp, that it occurs with petroleum and is emitted by volcanoes, especially by mud volcanoes. Hydrogen often accompanies methane in these cases, and has been found in the fumerolles of Iceland and Tuscany. These outbursts are only extreme manifestations of actions which have been silently in continual progress for ages. The occurrence of hydrogen occluded in rocks has been pointed out by Fouqué and by Tilden. M. Gautier has himself greatly extended earlier researches. He finds that many specimens of granite treated with water at 280° C. or with dilute acids at 100°, yield a considerable volume of gas. Thus, in one case, a kilogramme of granite heated with diluted phosphoric acid gave the following volumes in c.c.:—H_2S 1·2, CO_2 272·6, C_2H_2 12·3, CH_4 trace, N_2 (rich in argon) 230·5, H_2 53.

It seems probable that when the igneous rocks were solidifying and their components crystallising, they included small quantities of the primitive earth materials which now form the subjacent zone, that is to say, sulphides, nitrides, argonides, heliides, hydrocarbons, carbides, fluorides, iodides, phosphides, arsenides, &c. These substances, by the action of water, aided or not by acids, gave rise to the observed gases. As to the hydrogen, M. Gautier is assured by experiments, which he does not now detail, that it comes from (*a*) the action of water at a red heat on ferrous compounds, (*b*) the destruction by heat of hydrocarbons formed previously by the action of water on metallic carbides, (*c*) in a less degree by the action of water at a red heat on certain nitrides.

Hydrocarbons come from the action of water on small quantities of metallic carbides, especially those of aluminium and iron, included in the rocks.

Many more details of geological and chemical interest are given by M. Gautier. He insists that it is not necessary to imagine that water penetrates to the molten material lying below the solid crust of the earth. It is sufficient for the water to reach the low layers of rock containing these small quantities of included raw materials. On the other hand, it is not to be supposed that the gaseous products of the action of water on the raw materials will all escape from the surface. Some of the gases will combine with the rocks, and some on reaching the region of oxygen will be oxidised; but others, including methane, the petroleum hydrocarbons, nitrogen and hydrogen, not readily oxidised except at high temperatures, will escape into the air.

M. Gautier deals briefly with the question as to whether the hydrogen will tend to accumulate in the upper regions of the atmosphere. Without committing himself to a definite opinion, he quotes the views of Dr. Johnstone Stoney as to the impossibility of the earth's gravitational attraction being sufficient to retain helium or hydrogen. If the view is accepted that some of the hydrogen molecules at the fringe of the atmosphere have a velocity outwards of 11,000 metres per second, their escape would be possible, and we should have to picture a continual flux of hydrogen from the earth's surface through the atmosphere into interstellar space.

It is interesting to note that Profs. Liveing and Dewar incline perhaps to a different view. They say "if the earth cannot retain hydrogen or originate it, then there must be a continued accession of hydrogen to the atmosphere (from interplanetary space), and we can hardly resist the conclusion that a similar transfer of other gases must also take place."

Whatever view be correct as to the source and retention of atmospheric hydrogen, there can be no longer any doubt not only of its presence but of its abundance, and the establishment of this fact marks an advance in knowledge highly important from many points of view.

A. S.

SCIENTIFIC AGRICULTURE IN THE UNITED STATES.[1]

AGRICULTURAL experiment stations are now in operation under the act of Congress of March 2, 1887, in all the States and Territories of the United States. Agricultural experiments have been begun in Alaska with the aid of national funds, and an experiment station is in operation in Hawaii under private auspices. In each of the States of Alabama, Connecticut, New Jersey and New York a separate station is maintained wholly or in part by State funds, and in Louisiana a station for sugar experiments is maintained partly by funds contributed by sugar planters. Excluding the branch stations established in the several States, the total number of stations in the United States is 54. Of these 52 received the appropriation provided for in the act of Congress above mentioned. The total income of the stations is about 1,143,334 dollars, of which 720,000 dollars was received from the National Government, the remainder, 423,334.93 dollars, coming from the following sources: State Governments, 240,300.20 dollars; individuals and communities, 12,100 dollars; fees for analyses of fertilisers, 75,294.42 dollars; sales of farm products, 69,312.60 dollars; miscellaneous, 26,327.71 dollars. In addition to this the Office of Experiment Stations has an appropriation of 40,000 dollars for the past fiscal year, including 10,000 dollars for the Alaskan investigation.

The stations employ 678 persons in the work of administration and inquiry. The number of officers engaged in the different lines of work is as follows:—Directors, 71; chemists, 148; agriculturists, 68; experts in animal husbandry, 9; horticulturists, 77; farm foremen, 21; dairymen, 23; botanists, 52; entomologists, 48; veterinarians, 26; meteorologists, 17; biologists, 7; physicists, 7; geologists, 5; mycologists and bacteriologists, 20; irrigation engineers, 5; in charge of substations, 16; secretaries and treasurers, 24; librarians, 9; and clerks, 43. There are also 48 persons classified under the head of "miscellaneous," including superintendents of gardens, grounds and buildings, apiarists, herdsmen, &c. Three hundred and eight station officers do more or less teaching in the colleges with which the stations are connected.

During 1899 the stations published 445 annual reports and bulletins, containing 16,924 pages. Besides regular reports and bulletins, a number of the stations issued Press bulletins, which were widely reproduced in the agricultural and county papers.

In a recent report on the work and expenditures of the stations, Mr. A. C. True, the Director of the Experiment Station Office, makes the following general statements:—

The work of the stations during the past year has for the most part been along the same lines as heretofore, and in the

[1] Abridged from the *Experiment Station Record* (vol. xi. No. 9), published by the U. S. Department of Agriculture.

aggregate a large amount of useful work has been accomplished. By their own efforts and with the aid of the colleges of agriculture and the State boards or commissioners of agriculture, the stations are bringing their work home more closely to the farmers through publications, farmers' institutes, agricultural associations, home reading courses, and the Press. It is becoming evident that farm practice in the United States is being materially affected by the work of the stations, and they are more and more relied upon by our progressive farmers for advice and assistance.

The wisdom of Congress in making the Hatch fund a research fund is every year becoming more apparent. This Department is therefore disposed to more strongly insist on a strict interpretation of this act in this direction, and to hold that it is not only in accordance with the obligation, but also to the interest of the States, to devote the Hatch fund to investigations in agriculture and to supplement this fund as far as may be necessary to promote the interests of agriculture in other lines.

The movement for the improvement of courses of agriculture in the colleges with which the stations are connected is steadily growing. The past year has witnessed many changes for the better as regards specialisation of the work of instruction and the development of courses suited to the varied needs of students. More than ever before, the colleges are reaching out beyond their class rooms and are carrying useful instruction to the farmers through farmers' institutes, correspondence courses, and other forms of so-called university extension. As this outside work becomes better organised it is more apparent that it belongs to the college rather than the station.

As the work of both college and station grows in extent and complexity, it becomes more apparent that in order to perform the most efficient service the station should be organised strictly as a separate department of the institution with which it is connected, and that it should have an organisation so compact that its work may proceed in accordance with a schedule carefully planned and energetically administered. To secure this end, experience shows that it is quite desirable that the station should have a competent executive officer, who can devote his time very largely to planning and directing its operations, managing its general business, and representing its interests before the public. It is encouraging to observe that in several States during the past year these considerations have led to the more complete separation of the business of the station from the general business of the college, and to the appointment of a director of the station as a separate officer.

From the very first the stations in the United States have been largely engaged in the inspection of commercial fertilisers, and this work has been so efficiently and usefully conducted that from time to time additional inspection duties have been laid upon the stations. The movement for the establishment of different kinds of inspection service under authority of the National and State Governments is growing apace, and it is very important that the relations of this work to the other functions of the stations should be clearly understood. Soon after the establishment of the stations under the Hatch Act this Department ruled that the funds appropriated under this Act could not be legitimately applied to pay the expenses of the inspection and control of fertilisers. The same principle holds good with reference to other forms of inspection service demanded of the stations. While the methods and usefulness of inspection in any particular line are still problematical, it may be justifiable for a station to take up this work to a limited extent, but as soon as it becomes a matter of routine business the State should provide funds for its maintenance. If it seems expedient that any part of the inspection service should be performed by the station under State laws and at State expense, the matter should be so arranged as not in any way to interfere with the investigations of the station. It is a great mistake to divert the time and energy of a competent investigator to the toilsome routine work of inspection service.

The number and importance of the experiments which the stations are conducting in cooperation with practical farmers and horticulturists have greatly increased of late. Thousands of such experiments are now annually conducted in the United States. These range all the way from simple tests of varieties of plants to special experiments in the management of farm or horticultural crops, live stock, or particular operations, such as tobacco curing. It is coming to be more clearly recognised that the field operations in agriculture or horticulture conducted on the station farm need to be supplemented by similar work in a considerable number of localities in order to be of general usefulness to the State. By going into different localities, as the needs of its work demand, the station can make itself more useful to the State as a whole. Without doubt cooperative experiments need to be very carefully planned and thoroughly supervised to be successfully conducted, and their success depends on their quality rather than their number. It is encouraging to observe that more careful attention is being given to this important matter by station officers, and it is believed that this work may be made much more economical and useful than the permanent substations as ordinarily managed.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—In consequence of the death of Sir John Conroy, a tutorial fellowship in chemistry and physics, to be held in conjunction with the Bedford Lectureship, is announced at Balliol College. The fellow elected will be expected to supervise the whole science teaching of the College and to give instruction in chemistry and elementary physics. Applications, with the names of three persons to whom reference may be made, must be sent to the Master on or before April 18.

Profs. E. A. Minchin and A. Sedgwick have been appointed public examiners in zoology.

Scholarships in natural science are announced for June 18 at Merton College, New College, and non-collegiate students.

CAMBRIDGE.—The Smith's Prizes are awarded to Mr. G. H. Hardy and Mr. J. H. Jeans, of Trinity College. Mr. P. V. Bevan, of the same College, receives honourable mention. The prizemen were second and fourth wranglers respectively in 1898. Mr. Bevan was fourth wrangler in 1899.

Mr. L. Doncaster, of King's College, is nominated to the University table at the Naples Zoological Station.

Miss Meyer has presented to the Geological Museum the valuable collections made by her brother, the late Mr. C. J. A. Meyer.

THE senate of Glasgow University has resolved to confer the honorary degree of LL.D. upon Prof. A. W. Rücker, Sec. R.S., at the graduation ceremony on April 23.

THE council and senate of University College, Liverpool, has passed a resolution "that any measure dealing with the organisation and control of secondary education should provide for the direct representation of Universities and University colleges in the local authorities which such Bill may establish."

THE chair of natural philosophy in the University of Edinburgh will become vacant on April 29, in consequence of Prof. Tait's resignation. The patronage of the chair is vested in the curators. Applications, with relative testimonials, should be lodged with Mr. R. Herbert Johnston, secretary to the curators, at 4, Albyn Place, Edinburgh, on or before June 1.

THE annual general meeting of the Association of Technical Institutions, adjourned in consequence of the death of the Queen, will be held at the Fishmongers' Hall, London, on Tuesday, April 16, when the president, Sir Swire Smith, will take the chair and the president-elect, the Right Hon. Sir William Hart Dyke, M.P., will deliver an address.

FROM the ninth annual report of the Technical Instruction Committee of the City of Liverpool we derive the following facts as to valuable scientific instruction and work assisted by the committee. A course of four lectures was given on "Electric Vibrations," by Prof. O. J. Lodge, F.R.S., and a course of five lectures on "Oceanography," by Prof. Herdman, F.R.S. Both courses proved very successful in achieving the main object for which they were designed, viz., to bring before teachers of schools and classes some of the results of the progress of modern science, and to illustrate the methods and lines upon which this progress is proceeding. Admission to the courses was free to teachers of schools and classes in Liverpool. In 1900 the committee again renewed their grant (of 100*l.*) in aid of the scientific work carried on by the Lancashire Sea Fisheries Joint Committee. A permanent Sea Fisheries Laboratory in the Zoological Department of the University College, under the direction of Prof. Herdman, is partly supported by this grant; and trained assistants are constantly at work in this laboratory investigating fisheries' questions that may arise in

connection with the local industries. One of the rooms of the Zoological Museum at the University College of Liverpool is devoted to a permanent fisheries collection, illustrating the local fishing industries. The committee has thus proved that success attends the co-operation of the work of men of science in University Colleges with that of technical instruction, and their action should lead to the development of a similar policy in other cities.

SCIENTIFIC SERIALS.

Symons's Meteorological Magazine, February.—The pressure of the wind, by R. H. Curtis. In this paper the author deals with the wind-pressure from the point of view of the engineer and its effect upon structures, rather than from a purely meteorological standpoint. After the time of the collapse of the Tay Bridge, in December 1879, a good deal of attention was paid to this subject, and a committee was appointed to consider the question of wind force on railway structures. It estimated that the greatest pressure likely to be experienced over a large surface was 56 lbs. per square foot, but that, to ensure safety, bridges and similar structures ought to be built to withstand four times that pressure. This conclusion has probably led to an extravagant expenditure of money, as the records of improved and well-exposed anemometers have recently shown that this estimated pressure of 56 lbs. was greatly in excess of anything likely to be experienced. It is true that an Osler's pressure anemometer at Liverpool Observatory registered the extraordinary pressure of 90 lbs. on the square foot in March 1871. But this exaggerated record must have been due to a succession of impulses upon the pressure plate, as a wind force of less than 60 lbs. per square foot would, in all probability, have sufficed to carry away the anemometer itself. The author has paid much attention to this subject and will continue his interesting discussion.—Weather records at Slough, by Mr. R. Bentley. Instrumental observations were begun there by Sir William Herschel in the latter part of the eighteenth century. Mr. Bentley communicates classified rainfall values for 1874–1899, and has collected non-instrumental records of interesting phenomena in South Buckinghamshire from a very remote period.

American Journal of Science, February.—Apparent hysteresis in torsional magnetostriction and its relation to viscosity, by C. Barus. A differential method is employed, in which the two identical wires of iron or nickel to be compared are fastened coaxially one above the other, a mirror being attached between them. Accidental temperature effects are avoided by keeping the lower wire submerged in a tube of flowing water. A current can be sent either round or through the wire, so as to place the wire in either a longitudinal or circular field, the effect to be observed showing itself in a shifting of the fiducial zero. The phenomena are independent of the direction of the current and a larger angle of twist does not appear to magnify them. The results, which are somewhat complex, can be understood if magnetisation be regarded as a means of shaking up the molecular mechanism, and thus to produce temporary molecular instability or momentarily very low viscosity.—The dinosaurian genus Creosaurus, Marsh, by S. W. Williston. A description of a shoulder girdle and arm of a carnivorous dinosaur obtained from a deposit in the Freeze Out Mountains, Wyoming. The fossil is well differentiated from Allosaurus, although occurring with remains which may possibly belong to that genus.—The stereographic projection and its possibilities from a graphical standpoint, by S. L. Penfold. A continuation of a previous paper. The graphical methods are applied to some solutions of spherical triangles, in determining geographical distances, and to map projection.—On the melting point of gold, by L. Holborn and A. L. Day. These results have been already noted in the January number of *Wiedemann's Annalen*.—On some new mineral occurrences in Canada, by G. Chr. Hoffmann. The minerals described are lepidolite, newburyite, struvite, schorlomite, danalite, spodumene and uranophane.

Bulletin of the American Mathematical Society, February.—The seventh annual meeting of the Society was held in New York City, on December 28, 1900. Several important changes in the organisation of the Society were made, the membership of which has now reached the fine total of 357 names. Prof. F. N. Cole gives a brief recapitulation of advance since the foundation of the Society, and fully records the proceedings at the Christmas gathering. The titles of seventeen papers are given and abstracts of many of them are here printed. On some birational transformations of the Kummer surface into itself, by Dr. J. I. Hutchinson, is a paper read at the meeting. Another paper that was read is entitled "Theorems concerning positive definitions of finite assemblage and infinite assemblage," by C. J. Keyser. A third paper, by W. B. Ford, is entitled "Dini's method of showing the convergence of Fourier's series and of other allied developments." Short notice follows of Fehr's Application de la méthode vectorielle de Grassmann à la géométrie infinitésimale, by E. B. Wilson, and of the Annuaire pour l'An 1901, publié par le Bureau des Longitudes, by Prof. E. W. Brown. Notes and new publications as usual.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, February 21.—"An Investigation of the Spectra of Flames resulting from Operations in the Open-hearth and 'Basic' Bessemer Processes." By W. N. Hartley, F.R.S., Royal College of Science, Dublin, and Hugh Ramage, A.R.C.Sc.I., St. John's College, Cambridge.

Three papers on "Flame Spectra," by one of the authors, were published in the *Philosophical Transactions* for 1894. Parts I. and II., "Flame Spectra at High Temperatures," and Part III., "The Spectroscopic Phenomena and Thermochemistry of the Bessemer Process."

The spectroscopic results were quite different from those previously obtained by observing the "acid" process, as the continuous spectrum was much stronger. Many lines and bands new to the Bessemer flame spectra were observed.

Twenty-six plates of spectra were photographed. The spectra increase in intensity as the blow proceeds in the first stage, and this can only result from a corresponding increase in the temperature of the bath of metal and of the flame.

Considerable difficulty was experienced in the identification of some of the lines and bands; some were due to uncommon elements, and others were relatively much stronger than a study of the oxyhydrogen flame and other spectra of the same metals had hitherto shown.

Conclusions.

(1) Line spectra are not observed in the open-hearth furnace. This is attributed mainly to the fact that the atmosphere of the furnace is oxidising, and under these conditions, as Gouy has shown (*Phil. Mag.*, vol. ii., 1877, p. 156), only sodium gives a spectrum approaching in intensity that which it gives in a reducing flame.

(2) The phenomena of the "basic" Bessemer blow differ considerably from those of the "acid" process.

First, a flame is visible from the commencement of blowing. The immediate production of this flame is caused by carbonaceous matter in the lining of the vessel, its luminosity is due partly to the volatilisation of the alkalies, and to the incandescence of lime dust carried out by the blast.

Secondly, volatilisation of metal occurs largely at an early period in the blow, and is due chiefly to the smaller quantity of silicon present.

Thirdly, a very large amount of fume is formed towards the close of the second period. The flame is comparatively short, and the metallic vapours carried up are burnt by the blast.

Fourthly, the "over blow" is characterised by a very powerful illumination from what appears to be a brilliant yellow flame: a dense fume is produced at this time composed of oxidised metallic vapours, chiefly iron. The spectrum is continuous, but does not extend beyond wave-length 4000. The light emanates from a torrent of very small particles, liquid or solid, at a yellowish-white heat.

Fifthly, the spectra of flames from the first stage of the "basic" process differ from those of the "acid" process in several particulars. The manganese bands are relatively feeble, and lines of elements, not usually associated with Bessemer metal, are present. Lithium, sodium, potassium, rubidium and cæsium have been traced mainly to the lime used; manganese, copper, silver and gallium to the metal.

(3) Differences in the intensity of metallic lines. The intensity of the lines of any metal varies with the amount of the metal in the charge, but they are also to be traced to changes in temperature; as the temperature of the flame rises, some lines

fade almost away, others become stronger. The changes are more marked in the arc spectrum and still more in the spark spectrum of iron.

A new line of potassium with variable intensity. This line, wave-length approximately 4642, varies in intensity within somewhat wide limits. In a given flame its brilliancy is increased by diminishing the quantity of metallic vapour in the flame: this does not appear to depend altogether on the weakening of the continuous spectrum; it is probably due, in part at least, to the increased freedom of motion permitted to the molecules of the metal.

February 21.—"Notes on the Spark Spectrum of Silicon as rendered by Silicates." By W. N. Hartley, F.R.S.

March 7.—"On the Composition and Variations of the Pelvic Plexus in *Acanthias vulgaris*." By Mr. R. C. Punnett, B.A., Gonville and Caius College, Cambridge. Communicated by Dr. H. Gadow, F.R.S.

"Preliminary Communication on the Œstrous Cycle and the Formation of the Corpus Luteum in the Sheep." By F. H. A. Marshall, B A. Communicated by Prof. J. C. Ewart, F.R.S.

Physical Society, March 8.—Dr. R. T. Glazebrook, foreign secretary, in the chair.—A paper on a theory of colloidal solutions was read by Dr. F. G. Donnan. Assuming that a colloidal solution is not a true molecular intermixture, but a two-phase system consisting of exceedingly minute aggregates of the colloid distributed throughout the solvent, the object of the paper was to examine how such a state of affairs might be imagined to come about. By applying the fundamental notions of Laplace's theory of capillary forces to the statical (mechanical) equilibrium at the interface, it was shown that under certain conditions matter in bulk might disintegrate into a homogeneous liquid medium and yet not attain a state of molecular division, remaining distributed in the form of very thin filaments or sheets whose thickness is comparable with the sphere of molecular attraction. True solution, or molecular intermixture, is regarded, on the other hand, as arising from the kinetic flux of molecules across the interface. Dr. Gladstone said that the study of colloids was one which had been too much neglected. It involves both a knowledge of physics and of chemistry. A colloid is an unstable body and is always altering its composition. Water of combination is given off on heating, even if the surrounding atmosphere is saturated, and the colloid cannot take up the water again. It is impossible to separate colloids and crystalloids—they merge into one another. The transition forms are not uncommon. Dr. Lehfeldt asked if it had been proved that colloids have osmotic pressure. Prof. Threlfall said that in colloidal solutions some of the substance was not in suspension. Dr. Martin had filled a filter with silicic acid under pressure, and found that it allowed sugar solution to pass through but stopped colloidal solutions. The author had used opacity as a test for colloids, but silicic acid could be got transparent. There are two kinds of opalescence—one cannot be removed and exists because the substance is a two-phase system; the other can be removed with difficulty by filtering, and leaves a transparent substance. The want of transparency should be used cautiously as an argument. Dr. Donnan, in reply to Dr. Gladstone's remarks on the transition from crystalloids to colloids, said that a substance might be a crystalloid with one medium and a colloid with another. In reply to Dr. Lehfeldt, he said that the only evidence in favour of osmotic pressure of colloids is that colloidal solutions diffuse. He agreed with Prof. Threlfall that opacity should be used carefully as an argument, but stated that his theory referred to a two-phase system. —Mr. Appleyard then exhibited three pieces of apparatus. The first was a slide wire bridge for measuring conductivities of wires. The slide wire instead of forming two arms of the bridge forms only one, and the length used is proportional to the conductivity to be measured. If the arm which contains the standard wire used is altered, it becomes necessary to alter the divisions of the scale on the slide wire. This is done by a mechanical arrangement. The second piece of apparatus was a mechanical gauge for measuring the diameters of spheres. The sphere to be measured is placed between a metal face plate and a piece of glass at the end of the short arm of a pivoted lever. The end of the long arm of the lever moves over a graduated scale which is calibrated to show directly the diameter of the sphere. The third piece of apparatus was a galvanometer fitted up for lamp and scale work. The illumination was produced by a 4 volt ½-candle power lamp, and it was shown that very good results could be obtained from this by using a large condensing lens. Prof. Threlfall said he had usually used a straight piece of the lamp filament itself, instead of using the lamp in conjunction with a cross wire.—A paper, by Prof. R. W. Wood, on the production of a bright line spectrum by anomalous dispersion and its application to the flash spectrum, was postponed until the next meeting at Burlington House, when the subject will be experimentally illustrated by Mr. Watson.—The Society then adjourned until March 22, when the meeting will be held in the chemical laboratories of University College, London.

Geological Society, February 15.—Annual General Meeting.—J. J. H. Teall, F.R.S., president, in the chair.—It was stated that, the Council having undertaken to supply to the Regional Bureau of the International Catalogue of Scientific Literature the material referring to geology published in the British Islands, Mr. C. Davies Sherborn had been appointed to prepare and edit the catalogue-slips necessary for that purpose. The reports having been adopted, the medals and funds of the Society were awarded as already announced (p. 402).—The president then proceeded to read his anniversary address, in which he first gave obituary notices of several Fellows and Foreign Members deceased since the last annual meeting. He then dealt with the evolution of petrological ideas during the nineteenth century, especially as regards the igneous rocks. The discussions as to the origin of basalt and granite were referred to, and it was shown that the controversy regarding the latter rock had contributed largely to the clearing up of our ideas as to the nature of plutonic phenomena. The solution-theory propounded by Bunsen was especially emphasised, and its modern developments were briefly sketched. It was suggested that the next great advance will, in all probability, be the result of experiment, controlled by the modern theory of solutions, and carried out for the purpose of testing the consequences of that theory and discovering the modifications which may be necessary to adapt it to igneous magmas. The bearing which recent work on alloys had on petrographical problems was also referred to. The problem of the origin of petrographical species was next considered, and the growth of ideas on the subject briefly sketched. It was pointed out that although magmatic differentiation is accepted by many as an important factor in producing different kinds of igneous rocks, it does not rest on any assured experimental basis. Differentiation dependent on, or connected with, the crystallisation of definite minerals was reviewed more favourably; but it was pointed out that all theories of differentiation which are based on unaided molecular flow are subject to the criticism that the time required to effect any important differentiation appears to be too great. Reference was also made to recent work on the modification of igneous magmas by the inclusion and assimilation of rocks through which they pass; and the conclusion was reached that the origin of species, so far as igneous rocks are concerned, is a problem the final solution of which has been handed on by the nineteenth century to its successor.

Royal Astronomical Society, March 8.—Dr. J. W. L. Glaisher, F.R.S., president, in the chair.—Lantern slides were exhibited of photographs of the region of the new star in Perseus, taken by Mr. Stanley Williams. One, taken on February 20, only twenty-eight hours before its discovery, showed no trace of the Nova, though containing stars to about the twelfth magnitude.—Dr. Lockyer showed photographs of the spectrum of the new star, taken at South Kensington. The spectrum showed dark lines of hydrogen, and also broad, bright hydrogen bands displaced towards the red, apparently indicating two sources of light and enormous relative velocities. The spectrum showed the existence in the star of hydrogen, calcium, iron, &c.—Mr. McClean exhibited an enlargement from his photograph of the spectrum, in which he could find no trace of helium. The spectrum of the Nova resembled that of Sirius, but with bright bands of hydrogen; it was also much like that of Nova Aurigæ.—A photograph of the spectrum taken at Stonyhurst was also shown.—Mr. Newall exhibited and explained his photographs of details of the spectrum, taken at Cambridge.—Dr. Rambaut gave results of observations made at Oxford. The colour of the Nova was first of a bluish-white, becoming redder as it diminished in light.—The Astronomer Royal showed photographs taken at the Royal Observatory, where observations were made of the magnitude, which showed a gradual but not perfectly regular, diminution of brightness from 0·5 magnitude on February 25 to 3·1 magnitude on March 6.—Mr. Bellamy brought forward a series of measures

of the position of the Nova, from a photograph taken at the University Observatory, Oxford.—Mr. Bryan Cookson gave a description, illustrated with lantern slides, of a new photographic zenith telescope, constructed with a view to the determination of the constant of aberration. The essential feature of the ordinary zenith telescope is the *level*, but in this new form of the instrument there is no level, verticality of the axis being obtained by floating the supports of the telescope in a bath of mercury. Mr. Cookson also gave some preliminary results obtained with the new instrument.—Nine other communications were taken as read.

Linnean Society, February 21.—Dr. A. Günther, F.R.S., vice-president, in the chair.—Mr. R. Morton Middleton exhibited and made remarks on a series of Virginian oysters of certified ages.—Mr. H. E. Smedley exhibited with the aid of the lantern a series of photomicrographs illustrating the histology of various types of plants. Mr. Smedley also showed some fossil remains of *Balaena* from the Crag, with other undetermined bones.—A paper by Prof. E. Ray Lankester, F.R.S., and Mr. R. Lydekker, F.R.S., on the affinities of *Ælluropus melanoleucus*, was read by Mr. Lydekker. The authors based their views on an examination of a cast of the skull presented by the late Prof. Milne-Edwards to the Oxford University Museum, and certain limb-bones and a fine skull in the Natural History Museum, South Kensington, all of which were described. The conclusions arrived at were that in important and distinctive points *Ælluropus* agrees with *Ælurus* and *Procyon* (more closely with the former) and differs widely from *Ursus*, notwithstanding its external resemblance to the last named. The salient points in the anatomy of each were discussed, and the resemblances and differences made clear by a series of photographs which were exhibited.—A paper by Monsieur A. Gruvel, entitled "Étude d'une espèce nouvelle de Lepadides," was communicated by Prof. Howes, who gave an abstract of the same, and exhibited drawings of the new species (*Scalpellum maximum*) described by the author. The paper also dealt with examples of *Poecilasma carinatum* which were found attached to a specimen of the *Scalpellum*.

Anthropological Institute, February 25.—Prof. Haddon, F.R.S., president, in the chair.—Mr. H. Ling Roth read a paper on Maori tatu and moko. The paper, which was fully illustrated by lantern slides, opened with an explanation of the difference between tatu and moko; by the former is understood production of a pattern by puncturing the skin and depositing colouring matter under it; in the final state the skin is perfectly smooth. In moko, on the other hand, the instrument is a chisel and leaves slight grooves in the skin after the wound is healed. The Maoris made use of spirals and coils in their patterns, differing in this respect from other Polynesians. The instrument, which is really a miniature hoe, is placed on the skin and tapped with a mallet. The operation is extremely painful, involving great loss of blood, so that only a small portion of the pattern can be done at once. The portions of the body operated on are the face and thighs, and in the case of the latter the effect is that of an ornamental pair of drawers. The operation was begun at puberty and small additions were continually made, especially after a successful fight or on similar important occasions. The most elaborately tatued was most favoured by the fair sex. In some cases post mortem moko was employed to increase the value of a specimen.—Major-General Robley presented a drawing of a Maori war dance.

EDINBURGH

Mathematical Society, March 8.—Some elementary theorems regarding surds, by Prof. Chrystal.—Note on the application of complex integration to the equation of conduction of heat, by Mr. John Dougall.

PARIS.

Academy of Sciences, March 4.—M. Fouqué in the chair.—On the new star which recently appeared in the constellation of Perseus, by M. J. Janssen. In stars such as the sun, in which the temperature is too high for water to exist, as the temperature falls there must come a point at which combination of the hydrogen and oxygen will suddenly take place. This would be accompanied with an enormous and sudden increase of temperature and hence of light production, and this is put forward as a possible explanation of the appearance of a new star. At the moment of combination, on account of the pressures and temperatures developed, the rays of the spectrum ought to be considerably enlarged, and this is precisely what appears in the spectra obtained at Meudon.—Meridional sight with cylindrical mirror, by M. G. Lippmann. A description of an apparatus for measuring right ascensions, in which the meridian is shown as a luminous line projected upon the sky. With this apparatus a cross wire in the eyepiece is rendered unnecessary.—On the preparation and properties of sulphammonium, by M. Henri Moissan. The three varieties of sulphur were submitted to the action of liquefied ammonia at $-80°$ C.; no reaction takes place, but on allowing the temperature to rise slowly solution occurs with sulphur insoluble in carbon bisulphide at $-38°$, with prismatic sulphur at $-15°.5$, and with the octahedral variety at $-11°.5$. From this solution a new compound, sulphammonium, can be obtained, of a dark red colour, and having at $-23°$ the composition $(NH_3)_2S$, at $20°$, $(NH_3)_2S.2NH_3$, which is completely dissociable at the ordinary temperature and pressure, and which possesses the property of being able to add sulphur in the cold to a large number of simple and compound bodies.—A method of estimating sulphides, sulphydrates, polysulphides and hyposulphites coexisting in solution, in particular in certain mineral waters, by M. Armand Gautier. The method proposed is based upon the facts that sulphhydrates, distilled in a vacuum, give up all their sulphuretted hydrogen in excess of that required to form the monosulphide, and this, again, yields the whole of its sulphur on distilling in a current of carbon dioxide. Test analyses are given of a water prepared synthetically and of the mineral water of Labassère.—On germination in distilled water, by MM. P. P. Dehérain and Demoussy. Seeds can form their roots and commence their development in distilled water absolutely deprived of lime, although this development is arrested when the distilled water contains unweighable traces of copper.—A phototherapic apparatus without a condenser, by MM. Lortet and Genoud. The size of the active zone in the apparatus described may be varied from 1 to 6 cm. in diameter, the zone from an apparatus using a condenser being much smaller. The time necessary for the exposure is also reduced to one-fourth of that required in the older form of apparatus.—Observations on the brightness of the planet Eros made at the Observatory of Lyons, by MM. Guillaume, Le Cadet and Luizet. The results are shown in the form of a curve having a period of about 2h. 50m., the total variation of light being about two magnitudes.—On the variation of brightness of the planet Eros, by M. M. Luizet. A mathematical discussion of the results of the previous paper.—Variations of brightness of the planet Eros, by M. Baillaud. From observations made at the Observatory of Toulouse, the period between the times of maximum brightness is found to be the same as between the minima, 2h. 23m.—The elements of the system formed by the double planet Eros, by M. Ch. Andre. The time of revolution of the satellite of Eros is nearly that of Phobos, the eccentricity is nearly equal to that of the lunar orbit, and the mean density of the system is of the order of that of Mars.—On the period of the variability of brightness of the planet Eros, from determinations made at the Observatory of Toulouse, by M. L. Montangerand. The period deduced is 2h. 22m.—On the new star in Perseus, by M. M. Luizet. A comparison of the magnitude of the new star with α-Taurus, β-Gemini, α-Perseus, and γ-Cassiopeia.—Observations on the new star in Perseus, by M. H. Deslandres. A detailed study of the spectrum of the new star (see p. 477).—On a certain surface of the third order, by M. D. Th. Egorov.—On complete systems of partial differential equations, by M. Edmond Maillet.—On the propagation of the Hertzian oscillations in water, by M. C. Gutton. It is shown that the wave-length remains the same when the resonator and the transmitting wires are immersed in water.—The law of transparency of matter for the X-rays, by M. L. Benoist.—On the induced radio-activity provoked by radium salts, by MM. P. Curie and A. Debierne. The experiments cited show that the induced radio-activity is transmitted by the air, and this is in agreement with the hypothesis of Rutherford.—On a new method for determining the atomic weight of uranium, by M. J. Aloy. The nitrate is decomposed, and the ratio of nitrogen to uranium nitrate determined.—Thermal study of the ammoniacal aluminium chlorides, by M. L. Baud.—On a new silicide of cobalt, by M. Paul Lebeau. The new silicide, which has the composition CoSi, is obtained by heating metallic cobalt and copper silicide in the electric furnace.—On the mixed organo-magnesium compounds, by M. V. Grignard (see p. 477).—On an isomeride of anethol and on the constitution of the latter, by MM. Behal and Tiffeneau. Anisol, treated

with magnesium-methyl iodide, gives a propenyl anisol and a polymer. The composition of the ketone formed from this on hydrolysis leads to the conclusion that anethol possesses a propylenic chain.—On the phenylhydrazones of glucose and their multirotation, by MM. L. J. Simon and H. Bénard.—A general method for the synthesis of the naphthenes, by MM. Paul Sabatier and J. H. Senderens. At 170° to 200° all the hydrocarbons tried were readily hydrogenised by reduced nickel. Details are given of the preparation of the hexahydro-compounds of toleune, orthoxylene and its meta- and para-isomers, ethyl benzene, mesitylene, pseudocumene and propylbenzene.—The specific and latent heat of fusion of ethylene glycol, by M. de Forcrand.—On the constitution of gentianose, by MM. Ed. Bourquelot and H. Hérissey.—The treatment by oxygen at atmospheric pressure of persons poisoned by carbon monoxide, by M. N. Gréhaut. The elimination and disappearance of the poison is considerably accelerated by the use of oxygen, which thus becomes essential in the treatment of cases of carbon monoxide poisoning.—The analogies between the diastatic actions of colloidal platinum and those of organic diastases, by M. G. Bredig.—The coagulating properties of mucus and its origin and consequences, by MM. Charrin and Moussu.—On a differential histochemical reaction of leucocytes and on the experimental production and the nature of the chromatophile granulations of its cells, by M. Henri Stassano.—New observations on the organisation of the Gasteropods, *Pl. Quoyana* and *Pl. Beyrichi*, by MM. E. L. Bouvier and H. Fischer.—On the different cells of the ovary which intervene in the formation of the egg in insects, by M. A. Lécaillon.—On the mechanism of the propulsion of the tongue in amphibians, by M. Marcus Hartog.—On the geotropism of the roots of the vine, by M. J. M. Guillon.—On the discovery of a glossopterian flora and of the reptiles *Pareiasaurus* and *Dicynodon* in the upper Permian deposits of the north of Russia, by M. V. Amalitzky.—The tertiary and quaternary deposits of the valley of Bellegarde, by M. H. Douxami.

DIARY OF SOCIETIES.

THURSDAY, MARCH 14.

ROYAL SOCIETY, at 4.30.—The Action of Magnetised Electrodes upon Electrical Discharge Phenomena in Rarefied Gases: C. E. S. Phillips.—The Chemistry of Nerve-degeneration: Dr. Mott, F.R.S., and Prof. Halliburton, F.R.S.—On the Ionisation of Atmospheric Air: C. T. R. Wilson, F.R.S.—On the Preparation of Large Quantities of Tellurium: E. Matthey.

ROYAL INSTITUTION, at 3.—Greek and Roman Portrait Sculpture: Prof. Percy Gardner.

MATHEMATICAL SOCIETY, at 5.30.—On the Composition of Group-Characteristics: Prof. Burnside, F.R.S.—On the Use of Cauchy's Principal Values in the Double Limit Problems of the Integral Calculus: G. H. Hardy.—Some Algebraical Identities of Simple Arithmetical Application: Prof. Elliott, F.R.S.

SOCIETY OF ARTS (Indian Section), at 4.30.—The Growth and Trend of Indian Trade—a Forty Years' Survey: H. J. Tozer.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Some Notes on Polyphase Substation Machinery: A. C. Eborall.

FRIDAY, MARCH 15.

ROYAL INSTITUTION, at 9.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—Combined Trolley and Conduit Tramway Systems: A. N. Connett.

EPIDEMIOLOGICAL SOCIETY, at 8.30.—The Enteric Fever Mortality in Copenhagen from 1828–1898: Dr. N. P. Schierbeck.—The Effect of Sewerage and Water Supply upon the Behaviour of Enteric Fever in Buenos Ayres: Dr. J. T. R. Davison.

SATURDAY, MARCH 16.

ROYAL INSTITUTION, at 3.—Sound and Vibrations: Lord Rayleigh, F.R.S.

MONDAY, MARCH 18.

SOCIETY OF ARTS, at 8.—Electric Railways: Major P. Cardew.

ROYAL GEOGRAPHICAL SOCIETY, at 4.30.—The Topography of South Victoria Land: L. C. Bernacchi.

VICTORIA INSTITUTE, at 4.30.—Religion and Art: Rev. T. Hunter Boyd.

CAMERA CLUB, at 8.15.—Discussion on Panoramic Photography.

TUESDAY, MARCH 19.

ROYAL INSTITUTION, at 3.—The Cell as the Unit of Life: Dr. A. Macfadyen.

ZOOLOGICAL SOCIETY, at 8.30.—On New or Imperfectly-known Ostracoda, chiefly from a Collection in the Zoological Museum, Copenhagen: Dr. G. S. Brady, F.R.S.—On *Lemur mongoz* and *L. rubriventer*: Dr. C. I. Forsyth Major.—On the Hymenoptera collected in New Britain by Dr. Arthur Willey: P. Cameron.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Æsthetic Treatment of Bridge Structures: J. Husband.

MINERALOGICAL SOCIETY, at 8.—Notes on an Occurrence of Minerals at Haddam Neck, Connecticut, U.S.A.: H. L. Bowman.—On Calaverite from the Cripple Creek District, Colorado, U.S.A.: G. F. Herbert Smith.—On the Arrangement of the Chemical Atoms in Boracite and Cassiterite: W. Barlow.

ROYAL STATISTICAL SOCIETY, at 5.—Results of State, Municipal, and Organised Private Action on the Housing of the Working Classes in London and in other Large Cities in the United Kingdom: Dr. John F. J. Sykes.

ROYAL PHOTOGRAPHIC SOCIETY, at 8.—Photographing Stained Glass by the Three-colour Process: Chas. B. Howdill.

WEDNESDAY, MARCH 20.

SOCIETY OF ARTS, at 8.—Evolution of Form in English Silver Plate: Percy T. Macquoid.

GEOLOGICAL SOCIETY, at 8.—On a Remarkable Volcanic Vent of Tertiary Age in the Island of Arran, enclosing Mesozoic Fossiliferous Rocks: B. N. Peach, F.R.S., W. Gunn, and E. T. Newton, F.R.S.—On the Character of the Upper Coal Measures of North Staffordshire; their Comparison with those of Denbighshire, South Staffordshire, and Nottinghamshire; and their Relation to the Productive Series: Walcot Gibson.

ANTHROPOLOGICAL INSTITUTE (Albemarle Street), at 8.—Joint Meeting with the Folklore Society.—Sand Ropes and other Futile Tasks: G. M. Godden.

ROYAL METEOROLOGICAL SOCIETY, at 7.30.—Climate, and the Effects of Climate: Dr. Hugh Robert Mill.

ROYAL MICROSCOPICAL SOCIETY, at 8.—The Metallography of Iron and Steel: Wm. H. Merrett.

INSTITUTION OF MINING AND METALLURGY, at 8.—Annual General Meeting.—Followed by: The Electric Power Station at the Pierrefitte Mine: E. Henry Davies.—(1) Note on Smelting Lead-Copper Ore; (2) Note on Lead Assaying: P. R. Robert.

THURSDAY, MARCH 21.

ROYAL SOCIETY, at 4.30.—Studies in Visual Sensation (Croonian Lecture): Prof. C. Lloyd Morgan, F.R.S.

LINNEAN SOCIETY, at 8.—On the Intestinal Tract of Birds, and the Valuation and Nomenclature of Zoological Characters: P. Chalmers Mitchell.

CHEMICAL SOCIETY, at 8.—Researches on Morphine, Part II: S. B. Schryver and F. H. Lees.—The Constitution of Pilocarpine, Part II.: H. A. D. Jowett.—Note on the Latent Heats of Evaporation of Liquids: Holland Crompton.—(1) Action of Dry Silver Oxide and Ethyl Iodide on Benzoylacetic Ester, Desoxybenzoin, and Benzyl Cyanide; (2) Alkylation of Acylarylamines: G. D. Lander.

CAMERA CLUB, at 8.15.—Yorkshire Caves and Waterfalls: T. C. Hepworth.

FRIDAY, MARCH 22.

ROYAL INSTITUTION, at 9.—Some Recent Work on Diffusion: Dr. Horace Brown, F.R.S.

PHYSICAL SOCIETY (University College, Gower Street), at 5.—On the Expansion of Silica: Prof. Callendar, F.R.S.—The Spectroscopic Apparatus at University College: Dr. E. C. C. Baly.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Hunslet Railway and Bridge over the River Aire: O. L. McDermott.

SATURDAY, MARCH 23.

ROYAL INSTITUTION, at 3.—Sound and Vibrations: Lord Rayleigh, F.R.S

CELTIC TRADITIONS AND ANTHROPOLOGY.

Celtic Folk-lore, Welsh and Manx. By John Rhys, M.A., D.Litt., Hon. LL.D. of the University of Edinburgh, Professor of Celtic, Principal of Jesus College, Oxford. 2 vols., paged consecutively. Pp. xlviii+718. (Oxford: Clarendon Press, 1901.) Price 21*s*.

PROF. RHYS has done well to republish, in these two handsome volumes, the collections of Celtic Folk-lore contributed by him to the pages of *Y Cymmrodor* and the *Transactions* of the Folk-lore Society. For not only are they thus rendered accessible to a larger number of readers, but he has enriched them with considerable additions, and a valuable commentary. Had he seen his way to recast the original articles, with a view to a more complete classification of their contents, it would have avoided some repetition, and would have set the relations of the various tales in a clearer light. But we must be grateful for the work in its present form. To recast the articles would have been a troublesome process, and perhaps no classification would have been entirely satisfactory. Moreover, we should certainly have missed in any such rearrangement much of the genial charm of the collections as they first came from his pen, derived from the personal narrative of the collector. To a large number of his readers this would have been a sacrifice they might not be willing to make, even for the sake of theoretical order. When, however, the severely virtuous student, who, intent only on what he is to learn, would have preferred to make this or any other sacrifice, has calmed his ruffled feelings and settled down to his task of learning, he will speedily realise how important a contribution to anthropology, and in particular to Celtic archæology, he has before him.

The chief intent which runs through the commentary is to determine so far as possible the race-elements that have gone to fashion the composite people of Wales, now so thoroughly welded together in historical memories and in political, religious and artistic aspirations. To this Prof. Rhys makes the whole of his collection subservient. Though he modestly disclaims the title of "folk-lorist," no living man has probably so wide a knowledge of the folk-lore of his native country, and certainly none has brought to its elucidation a scholarship so profound. His open-mindedness and candour are as remarkable as his scholarship. Consequently the present work is greatly in advance of his Hibbert Lectures as an exposition of the origin and real meaning of Celtic traditions. His theory, as summed up in the final chapter, is that in these traditions we have traces of at least two pre-Celtic races: first, a dwarf population inhabiting underground dwellings, and at a level of civilisation no higher than that of the present-day inhabitants of Central Australia; and secondly, the enigmatical people over whom Monkbarns and his guest fought with so much vigour, the Picts, "whose affinities appear to be Libyan, possibly Iberian." That a dwarf race was widely spread over this island cannot be questioned. Whether the bee-hive huts of Scotland and Ireland belonged to them is not quite so certain. In Roman times, and in the south of what is now England, they occupied ordinary wattle-and-daub huts. Prof. Rhys attributes wholly or partially to them birth-stories like those of Cuchulainn and Etain, of which the chief characteristics are virgin-birth and re-incarnation. He acutely points out that in the Cuchulainn story we have "two social systems face to face in Ulster," one of which recognised fatherhood, while the other did not. But alike the story-incidents and the corresponding superstitions are known practically all over the world. It is therefore impossible to fix the dwarf-race with responsibility for them. Besides, upon his own showing, the social organisation of the Picts was founded upon mother-right, and it is to the Picts that Scottish tradition assigns the mounds as dwellings.

In my opinion folk-lore seldom yields trustworthy evidence of race. What it does yield is evidence, often of the most decisive weight, of social states, of belief and practice. That the Welsh are descended from a people who were organised on the basis of mother-right, and believed in transformation, Prof. Rhys has rendered fairly certain from the traditions embodied in their literature, or found by himself in the mouths of the peasantry. Whence the organisation and belief in question were derived must be discovered, if at all, from evidence of another kind, that is to say, from philology and archæology. With the aid of his rare philological learning the author has illuminated many a dark place in the *Mabinogion* and in the folk-tales, though he has failed to solve the riddle which would, perhaps, tell us more of the origin of the fairies and of the descent of the Cymric people than any other incident in the stories, namely, the riddle of the non-Welsh names Penelope, Belene and others attributed to the fairy heroines of so many Welsh tales.

If, however, the folk-tales of the present day fail to yield sure evidence of race, some of those embodied in the *Mabinogion* do. But it is to be obtained rather in the names than in the incidents. It is common ground, for example, between Welsh and Irish Celticists, that there is a Goidelic element in the *Mabinogion*. The question is whether the stories were imported ready-made from Ireland, or grew on the soil of Wales and were adopted and adapted by the Cymric-speaking Celts from the Goidelic and Goidelised peoples they found in occupation of the country when they invaded it. The chapter on place-name stories (and in particular Prof. Rhys' analysis of the Hunting of the Twrch Trwyth) has gone far to settle this question. It must now be held, as the better opinion, that the *Mabinogion* stories which point most strongly to Irish influence, or indeed Irish origin, were taken over from the Goidelic substratum of the nation.

It would be easy to linger on many a delightful page of these fascinating volumes. Prof. Rhys always writes with humour. His gravest discourses are tempered with a smile. But, for all that, they are none the less grave in purpose. He has done more than any other man to rouse in his fellow-countrymen an intelligent interest in their history, language and literature. In conjunction with Mr. Brynmor Jones he has placed the study of Welsh history and institutions at last on something like a sound basis. So here he begins by laying down the maxim that—

"the history of no people can be said to have been written so long as its superstitions and beliefs in past times have not been studied; and those who think that the legends here recorded are childish and frivolous, may rest assured that they bear on questions which could not themselves be called either childish or frivolous."

Further on he returns to the subject:

"With regard to him," he says, "who looks at the collecting and the studying of folk-lore as trivial work and a waste of time, I should gather that he regards it so on account, first perhaps, of his forgetting the reality their superstitions were to those who believed in them; and secondly, on account of his ignorance of their meaning. As a reality to those who believed in them, the superstitions of our ancestors form an integral part of their history. However, I need not follow that topic further by trying to show how 'the proper study of mankind is man,' and how it is a mark of an uncultured people not to know or care about the history of the race. So the Roman historian, Tacitus, evidently thought; for, when complaining how little was known as to the original peopling of Britain, he adds the suggestive words *ut inter barbaros* 'as usual among barbarians.' Conversely, I take it for granted that no liberally educated man or woman of the present day requires to be instructed as to the value of the study of history in all its aspects, or to be told that folk-lore cannot be justly called trivial, seeing that it has to do with the history of the race—in a wider sense, I may say, with the history of the human mind and the record of its development."

There are many scientific men who need to lay to heart this protest.

A full index is given, and a most useful bibliographical list of references. E. Sidney Hartland.

ALKALOIDS.

Die Pflanzen-Alkaloide. By Jul. Wilh. Brühl, Professor in the University of Heidelberg, and Eduard Hjelt and Ossian Aschan, Professors in the University of Helsingfors. Pp. xxii+586. (Brunswick: Friedrich Vieweg und Sohn, 1900.) Price Mk. 14.

THE progress that has been made in the rapidly developing fields of organic chemistry can be best estimated when recognised authorities, such as the authors of the present volume, furnish chemists with special monographs dealing with those groups of compounds in which the writers can lay claim to an expert knowledge. As a class the vegetable alkaloids, which are dealt with in this volume, are of exceptional interest, not only on account of their wide distribution as natural products, but also because of their remarkable physiological actions. It is interesting to note, in reading through this admirable summary of the existing state of knowledge in this branch of chemistry, what great strides have been made towards a more definite conception of the structure or "constitution" of the molecules of these compounds within the last few years. At the present time, the synthetical achievements in this field are not numerous. The first complete synthesis of an alkaloid was that of coniine by Ladenburg in 1886, followed soon after by the synthesis of trigonelline by Hantzsch and Jahns. The latter chemist succeeded in synthesising arecoline in 1891, and the synthesis of piperine from piperidine and piperic acid by Ladenburg and Scholtz in 1894 may be said to complete the list of total syntheses thus far accomplished. But several partial syntheses have to be recorded, viz. aconitine from aconine and methyl benzoate, cocaine from ecgonine and benzoic anhydride; and one step towards the synthesis of hydrastine was made in 1895 by Fritsch.

The effect of this more intimate knowledge of the chemical constitution of the alkaloids is evident in the classification adopted in the present work. It is, in fact, now possible to refer large numbers of these compounds to different groups, each group having a well-known organic base as its parent form. Every one of the four parent compounds, viz. pyrrolidine, pyridine, quinoline and isoquinoline, are, it may be of interest to point out, capable of being completely synthesised. A brief sketch of the mode of treatment will enable our readers to form an idea of the value of this monograph by Prof. Brühl and his colleagues.

The introductory chapter deals with the history, distribution, preparation and properties, modes of decomposition, synthesis, physiological action, detection and estimation, and other general considerations relating to the group as a whole. This is followed by the chapter on the alkaloids of the pyrrolidine group, which comprises the hygrines and cuskhygrine. The second chapter contains an account of the alkaloids of the pyridine group, the latter comprising twelve subdivisions trigonelline, the jaborandi alkaloids, areca alkaloids, conium alkaloids, piperine, chrysanthemine, nicotine, solanum bases such as atropine, hyoscyamine, tropacocaine, madragorine, &c.; the alkaloids of coca, the alkaloids of pomegranate root-bark, sparteine and cytisine. The third chapter comprises the quinoline group, and, although divided into only two subdivisions, is very rich in individual compounds, since it includes the very numerous cinchona alkaloids and those of the plants belonging to the genus *Strychnos.* In the fourth chapter, the authors treat of the alkaloids of the isoquinoline group, comprising more than twenty opium alkaloids, hydrastine and canadine, and the alkaloids of *Berberis* and *Corydalis.*

The four chapters, the contents of which have been briefly referred to, deal with those alkaloids which are susceptible of chemical classification by virtue of our knowledge of their constitution. Whether with the progress of chemical science any or all of these formulæ may not require modification—and many of them are confessedly but tentative—does not affect the main question as to the atomic complexes from which the various alkaloids are derivable, and the reference of a particular alkaloid to any one of the four groups may be looked upon as a definite allocation of the compound with reference to its parent complex, whether the latter is genetically connected with its derivative by actual laboratory processes or whether the connection has only been inferred by indirect methods. The remaining alkaloids, which are distributed through the sixteen subdivisions constituting the fifth and last chapter, are, however, classified botanically rather than chemically, since their chemical constitution is unknown and only empirical formulæ can at present be assigned. Thus we

have alkaloids from cryptogamic plants such as ergotinine, lycopodine and pillijanine, and then following these the alkaloids from twelve families of flowering plants, viz. Coniferæ and Gretaceæ, Liliaceæ, Apocynaceæ, Aristolochiaceæ, Buxaceæ, Lauraceæ, Papilionaceæ, Loganiaceæ, Papaveraceæ, Ranunculaceæ, Rubiaceæ and Rutaceæ. A number of odd alkaloids and a few glyco-alkaloids conclude the work. In some of the numerous alkaloids considered as of unknown constitution, a certain amount of knowledge may be said to have been acquired in the direction of structural formulation. To illustrate this point, consider, for example, colchicine from *Colchicum autumnale*, which is empirically written $C_{22}H_{25}NO_6$. It is known, chiefly through the researches of Zeisel, that this alkaloid is a methyl ester containing four methoxy-groups and one acetamino-group. Its formula thus becomes :—

$$C_{15}H_9(OCH_3)_3\left\langle\begin{array}{l}COOCH_3\\ NH\ .\ COCH_3\end{array}\right.$$

and it is obviously a derivative of a phenolic amino-acid. But the constitution of the hydrocarbon complex $C_{15}H_9$, is still unknown, and the placing of the compound among the alkaloids of unknown constitution is thus justified. It is of interest to note in passing, as an illustration of the richness of this field of plant chemistry, that in this fifth chapter alone more than one hundred alkaloids of unknown constitution, but which are nevertheless definite chemical "individuals," are treated of. It may be further mentioned that under the term glyco-alkaloids the authors comprise compounds such as achilleine, solanine, moschatine and vicine, which split up on hydrolysis into glucose and a base.

A work such as that which forms the subject of the present notice cannot be criticised as a literary production. It belongs to that class of books which, being of the nature of monographs, are absolutely indispensable to all who are interested in the progress of organic chemistry, whether as students, investigators, teachers, pharmacologists or manufacturers. It sums up and presents in a systematised form the achievements of research in this particular field, and as a special work it may be said to have no competitor since, as the authors point out in the preface, the standard works on this subject by Pictet (1891) and Guareschi (1896) are already behind the actual state of knowledge in this domain, the boundaries of which are being extended with such astonishing rapidity. In writings of this class, where chemical compounds are dealt with from the historical point of view as well as from the most recent standpoint, there is often a tendency to spin out the history in wearisome detail. No fault can be found on this score with the authors' treatment; their general histories, as well as their histories of the individual alkaloids, are marvels of succinctness. We have long been in the habit of looking to continental writers for such monographs, and if our own specialists have hitherto failed in contributing such standard works to chemical literature, there is some compensating satisfaction in the present case, since the volume under notice is a special contribution to the German edition of an English work, viz. Roscoe and Schorlemmer's well-known "Treatise on Chemistry." R. MELDOLA.

SOUNDINGS IN THE NORTH ATLANTIC.

On the Results of a Deep-Sea Sounding Expedition in the North Atlantic during the Summer of 1899. By R. E. Peake, M.Inst.C.E. With Notes on the Temperature Observations and Depths, and a Description of the Deep-Sea Deposits in this Area. By Sir John Murray, K.C.B., F.R.S. Pp. 44. (London: John Murray, 1901.) Price 5*s*.

THIS little book, the latest of the "Extra Publications" of the Royal Geographical Society, ought effectually to attain at least one of its main objects, which is "to call attention to the assistance that Telegraph Cable Companies render towards improving our knowledge of the character and condition of the ocean's bed." The immense amount of valuable work done at sea every day by the commanders and officers of all kinds of ships deserves far more cordial recognition than it usually receives, especially in this country. The ordinary navigation of a ship involves daily observations of quite as great difficulty and complexity as any in the routine scientific work of a deep-sea expedition, and sailors not only have done, and do, much in the way of special observations of all kinds, but they are able and willing to do more. All they need is to be told what is wanted, and to be encouraged occasionally by satisfactory evidence that their labour is not thrown away. It may be hoped that the inauguration of the British Pilot Chart of the North Atlantic, and the publication of a paper like the present by the Royal Geographical Society, will lead to still fuller recognition of what must probably remain the only available methods of systematic and continuous investigation in ocean meteorology and oceanography.

The expedition here described was sent out to survey routes of cables which the Deutsch-Atlantisch Telegraphengesellschaft and the Commercial Cable Company had decided to lay; the former between Germany, the Azores and New York, and the latter between Ireland, the Azores and Nova Scotia. The preliminary survey was undertaken on the advice of Messrs. Clarke, Forde and Taylor, engineers to the companies. Mr. Peake was responsible for the plan of the survey and the supervision of the operations, and the work was carried out by the Telegraph Construction and Maintenance Company's s.s. *Britannia*, Captain H. Woodcock. The *Britannia* left England on May 4, 1899, and returned on August 3, having made 477 soundings, from most of which samples of the bottom were obtained, and 150 observations of bottom temperature. A large number of current observations were also recorded. The route is described as follows:—A large number of soundings were first taken between Fayal and Flores, on the Azores bank; next a line from south of Flores to New York; then a line from Cape Canso, Nova Scotia, towards the north of Flores. Different parts of the Azores bank were then surveyed in detail, and a line run to the coast of Ireland; and finally the ship returned to the Azores bank and sounded north-eastward to the mouth of the English Channel.

The results of the expedition are dealt with under four heads—depths, bottom temperatures, currents, and

nature of the bottom. A new map shows the distribution of deposits in the North Atlantic according to recent information, and an inset, based principally on the soundings of the *Britannia*, shows the outline of the Azores bank.

The lines of soundings fall naturally into three groups; those between the Azores and the British Islands, those between the Azores and North America, and those on the Azores bank. In each case new discoveries of interest have been made. On the first line a new depression, with soundings over 3000 fathoms, the "Peake deep," has been found; but the chief feature is the discovery of numbers of shoals rising steeply from over 2000 fathoms to within 1200 and 1400 fathoms of the surface, evidently the summits of submarine cones. The more southerly of the two lines between the Azores and North America revealed the important fact that the "tail" of the great Newfoundland bank extends much farther south than has hitherto been supposed. The *Britannia* has added largely to Thoulet's chart of the Azores bank, but the ground is so irregular that much sounding still remains to be done; the bank is described as being probably "a series of small hills, no doubt due to volcanic action."

The observations of bottom temperature, which were made with thermometers of Six's pattern, consist of two series of parallel lines, one double line between the Azores and the British Islands, and another between the Azores and America. It is pointed out that, on the whole, these observations give temperatures above the mean assumed in the *Challenger* report for this region of the ocean; but as that value is merely the average of the observations existing at the time, the volume of water at different temperatures not being taken into account, the difference may not be due to actual change. On the other hand, the *Britannia* observations show that in each of the double lines the temperatures are different; of the Azores-America line, the more northerly gave the higher readings at depths below 2000 fathoms; of the Azores-Europe line, the more southerly. It is suggested that these differences are due to actual change occurring between the dates of observation, and this view is supported by reference to the different temperatures observed in the south-west Pacific by H.M.S. *Egeria* in 1889 and H.M.S. *Penguin* in 1897. From the observations of H.M.S. *Jackal* in 1893, the writer showed that in the Færoe-Shetland Channel temperature was not constant at depths of at least 400 fathoms, and it was further shown that the variations were due to differences of level in the movements of water. The results of more recent work go to show that the active circulation of the eastern and western Atlantic consists chiefly of stream currents comparatively near the land, developed by the drift movements of the central areas and altogether separated by them. The currents on the eastern side are chiefly caused by the banking up of water from the west-wind drifts, and while most of this water escapes laterally to north and south, there is also a descending movement—hence the high temperatures in the depths. It is known that the horizontal streams are liable to great variations, partly seasonal, partly irregular, and the observations of the *Britannia* seem to prove that the vertical movements undergo corresponding changes. The variations of temperature may be regarded as directly due to movements of water, and therefore as seasonal in only a secondary sense, if at all.

The samples of deposits collected by the *Britannia*, numbering 432, are very fully described by Sir John Murray. The map shows two considerable alterations when compared with that of the *Challenger* report. First, the red clay area is extended northward from the deep water round Bermuda and passes directly into the blue mud south of Newfoundland. This abrupt transition to a terrigenous deposit is accounted for by the great distance to which continental detritus is carried by icebergs. Second, the pteropod ooze region round the Azores is restricted to a smaller area than before, although it is noted that the characters of this deposit are not well marked, and that it is difficult to classify some samples as pteropod or globigerina with certainty. Many samples from moderate depths near the Azores contain fewer pteropods than those obtained from deeper water farther north.

H. N. D.

OUR BOOK SHELF.

Modern Astronomy. Being some Account of the Astronomical Revolution of the last Quarter of a Century. By H. H. Turner, F.R.S. Pp. xvi+286. (Westminster: Archibald Constable and Co., Ltd., 1901.) Price 6*s*. net.

THE Savilian professor is so strongly impressed with the magnitude of the changes which have taken place in astronomical methods during the last quarter of a century that he does not hesitate to describe them as revolutionary. The task which he has set himself in this book is to give a brief review of the present situation, pointing out the nature of the changes rather than giving a complete account of them or of the discoveries to which they have led. The book can thus in no sense be regarded as a reference or text-book, but it may be remarked that elementary explanations have usually been introduced to make the matter generally intelligible.

Several quotations are given as an indication that about 1875 there was a feeling that novelties in astronomical methods or results were no longer to be expected. Such a feeling, if it existed, was certainly premature. New instruments of precision have been invented or erected; telescopes of increased size and novel construction have been made; photography has come to aid the astronomer in numberless ways; astrophysics has become an important branch of the subject, with almost boundless possibilities; and even in mathematical astronomy new methods of treating the lunar and planetary theories have been introduced.

This progress is treated under the four heads, "Modern Instruments," "Modern Methods," "Modern Results" and "Modern Mathematical Astronomy." Occasional overlapping and repetition is the natural outcome of this classification, but the book provides an interesting and fairly connected account of several departments of astronomical work. The treatment of astrophysics, however, leaves much to be desired. There is practically nothing in the book relating to the great advances in our knowledge of the sun as a result of recent eclipse work, and it is especially to be regretted that the evidences of stellar evolution are not more fully set forth. There are other indications of the author's unfamiliarity with the progress of astrophysics; on p. 239, for instance, he states that no supposition allied to that of a revolving companion will explain the variability of stars in clusters, whereas the collisions of revolving swarms of meteorites at periastron explain the light curves completely. For the sake of historical accuracy,

it should have been stated on p. 91 that the original idea of the spectroheliograph was due to Dr. Janssen, who first suggested it at the Exeter meeting of the British Association in 1869. Again, with reference to the first observation of the spectrum of a nebula, it is stated (p. 242) that "it was seen at a glance that the spectrum consisted of a few bright lines," though the observer at first attributed what he saw to some possible derangement of his instrument.

Looking forward, Prof. Turner believes that, among other changes, the transit circle will be gradually superseded by the almucantar for star observations, and by the heliometer for observations of the positions of planets, and in celestial photography he predicts a great future for the portrait lens.

The illustrations, some thirty in number, are of indifferent quality, and that of Eros, on p. 109, is almost unintelligible.

Chemistry an Exact Mechanical Philosophy. By Fred. G. Edwards, Inventor of Atomic Models. Pp. xii + 100. (London: J. and A. Churchill, 1900.)

"THE object of this work is to determine the exact shape of the atoms, to find their relative position in space, and to show that chemical force is purely a function of matter and motion." Further, "the shapes obtained for the different atoms is the subject-matter of a British patent (atomic models) dated 1897." Again, "the conclusions herein deduced (when accepted as true) will form a fitting climax to the discoveries of a century which has produced the atomic theory of Dalton, the theory of heat as a mode of motion, and the discoveries of the correlation of physical forces, and that force, like matter, is indestructible."

For the scientific reader there is little need to add any comments to these quotations. There is, however, always the possibility that an author may have a good idea but an unfortunate way of presenting it, and one does not forget that "the law of octaves" was received with something like ridicule. It is necessary to add, therefore, that a careful examination of the present work, made with every desire to find precious metal in it, has failed to reveal anything that seems likely to aid the advancement of science.

In dealing with the *exact shape* of atoms, the author starts with the assumption that the lightest known element, hydrogen, consists of two tetrahedra placed base to base, and that the atoms of the whole of the remaining elements may be similarly formed by tetrahedra built up symmetrically, every two tetrahedra representing one unit of atomic weight. It is practically impossible, without the models before one, to judge whether there is any outcome from this view of things that compensates in any degree for its arbitrariness and complexity. There can be little question, however, that as a whole the book and its doctrines will not command the serious attention of men of science whose leisure and patience are limited.

A. S.

The Chemists' Pocket Manual. By R. K. Meade, B.S. Pp. vii + 204. (Easton, Pennsylvania: The Chemical Publishing Co., 1900.)

A LARGE amount of information of use to professional chemists is brought together in this pocket book. The tables include almost everything to which occasional reference has to be made in chemical laboratories; and with the formulæ, calculations, physical and analytical methods, should be of service not only to chemists, but also to assayers, metallurgists, manufacturers and students. Among the points worthy of special mention are the applications of graphic methods to conversion tables; and the descriptions of select methods of technical analysis.

The Use of the Method of Least Squares in Physics.

THE application of the method of least squares to physical measurements is described in several standard text-books—to wit, Kohlrausch's "Introduction to Physical Measurements" (third edition, 1894), Stewart and Gee's "Elementary Practical Physics" (1885), and others. In none of these is it pointed out that the method *as set forth* offers in certain cases a choice of results, and that the solution is practically unique only if a sufficient number of observations be taken. Nor is any indication given how the method is to be applied when none but a small number of observations is available. Since the method is intended for use only when a high degree of refinement is aimed at, these points are of practical importance.

As illustrating the necessity for examining the matter, we may take the example given by Kohlrausch on p. 13 of the book referred to above. The object is to determine the law connecting the length L and temperature θ of a standard metre bar from the following four observations:—

θ . . . . =	20°,	40°,	50°,	60°
l (the excess over 1 metre) =	·22mm.,	·65mm.,	·90mm.,	1·05mm.

The law deduced is

$$L = 999{\cdot}804 + 0{\cdot}0212\theta.$$

It is not, however, pointed out that the law would be different if the equation connecting x and y, in this case θ and l, were written to begin with in a slightly different form. On the contrary, the above solution is presented as if it were altogether beyond doubt.

In the working of the example as given by Kohlrausch, the equation is written

$$y - ax - b = 0;$$

but if it be written

$$cy - x - d = 0,$$

and exactly the same procedure as that adopted in evaluating a and b be followed in determining c and d, the law thence deduced from the observations becomes

$$L = 999{\cdot}800 + 0{\cdot}0213\theta.$$

It will be seen that the constants in these two laws differ by one in two hundred, or 0·5 per cent., as regards the significant figures; and that from the precisely similar way in which they are obtained, they are each equally entitled to recognition.

In fact, corresponding to the values for a and b usually given, viz.:—

$$a = \frac{\Sigma x\Sigma y - n\Sigma xy}{(\Sigma x)^2 - n\Sigma x^2};\ b = \frac{\Sigma x\Sigma xy - \Sigma x^2\Sigma y}{(\Sigma x)^2 - n\Sigma x^2},$$

there are always another pair of values, giving the second form of the law, viz.:—

$$a' = \frac{(\Sigma y)^2 - n\Sigma y^2}{\Sigma x\Sigma y - n\Sigma xy};\ b' = -\frac{\Sigma y\Sigma xy - \Sigma y^2\Sigma x}{\Sigma x\Sigma y - n\Sigma xy}.$$

The first pair of values corresponds to the supposition that the x measurements are guaranteed correct, and the experimental errors are all confined to the y measurements; and the second pair corresponds to the supposition that the y measurements are correct and the errors are all in the x measurements. The two lines

$$y = ax + b$$
$$y = a'x + b'$$

intersect at the centre of mass of the system of points obtained by plotting the observations.

The question naturally arises: How shall a relatively small number of observations, or a series of observations which are relatively discordant, be made to furnish the best mean result obtainable when no other observations are available?

In order to answer this question, we may recur to the remark above that differences in the result are obtained by writing the equation in different forms. The various forms of the equation correspond to the several directions in which the divergencies of

the plotted observations from the graph of the law are to be considered. For instance, when the equation is written

$$y_1 - ax_1 - b = \delta',$$

the divergence δ' is measured along the ordinate; but when it is written

$$cy_1 - x_1 - d = \delta'',$$

the divergence δ'' is measured in the direction of the abscissa. Now if the divergencies were measured at right angles to the graph, and the sum of the squares were made a minimum, the graph would be the principal axis of inertia of the system of points. This line passes through the intersection of the other pair of lines, and gives a smaller sum of squares than any other line. When the number of points is very great, all three lines become sensibly coincident.

We may conclude, then, that when the observations are numerous and fairly concordant, the method of least squares, applied in the manner commonly taught, will give a practically unique result. But if in any particular case there be any doubt on this point, by reason of the number of observations being small, or the discrepancies between the observations being very great, it would appear to be desirable to find both the lines corresponding to the values of a, b and a', b', given above, in order to test the question. In the event of the difference between the pairs of constants obtained not being negligeable, the proper line to be made use of, in preference to either of the two others found as above, would seem to be the principal axis of inertia.

The Collection of Material for the Study of "Species."

STRANGELY enough, while the publication of "The Origin of Species" and the research which has been carried on since Darwin wrote his epoch-making work have completely revolutionised the morphologist's conception of what is a "species," nearly all the "systematic" work which is published even at the present day, especially in those branches of biological science where the amateur collector exerts most influence, is based upon the principles founded by Linnæus. These principles, while they were perfectly logical in pre-Darwinian days, are now, however, quite obsolete and out of harmony with the current state of biological knowledge. With a view to bringing scientific practice more into accord with scientific theory, a paper to which I listened at a recent meeting of the Linnæan Society suggested a reform in the present system of species nomenclature. Since, however, the great majority of those who describe "species" are unfortunately not in a position to realise how great indeed is the necessity of some such reform, it will probably not obtain immediate support from the systematists. The average "systematist" still holds the pre-Darwinian view of "species"; and, as the great bulk of the material at his disposal in public and private collections is of little value for the proper study of taxonomy, he quite fails to see how absolutely untenable his position really is. He does not realise how utterly impossible it is in certain groups to assign limits to the variability of "species," and it will never occur to him that two specimens superficially alike in all respects may quite possibly have been evolved along entirely different paths.

It is not my intention here to enter into a discussion as to whether a system of provisional names, such as is suggested by Mr. Bernard, might not be of distinct advantage in at least some branches of zoological inquiry; what I do wish to call attention to now is the necessity, if any decided advance is to be made in the study of taxonomy, for a sweeping change in the present system of collecting material, and in its representation in collections. The following remarks bear particularly upon the case of the mollusca, of which group I have personally most knowledge, but they are, of course, more or less applicable to other branches.

The taxonomist requires as a basis for his investigations to know as exactly as may be the range of variation which those forms in which he is interested experience at the different stations over which they occur. This knowledge is obviously most satisfactorily acquired by personal observation on the spot; but, as this is seldom practicable, the student is in general forced to rely upon material collected by others. Unless this material has been properly collected, the conclusions based upon it are likely to be erroneous; and most of the material available to the student of such groups as the Mollusca is eminently unsatisfactory. Apparently the aim of many conchologists is to represent (?) in their collections the greatest possible quantity of "species," each by a certain definite number—usually three—of "fine specimens." These may be as unlike the ordinary examples of the form as can be; and, whether they are localised or not is of little account, so long as they be fine. If a larger or more brilliantly coloured specimen is obtainable it replaces one of the mystic three.

Large Series necessary.—Little can be known about a species until large series have been examined; yet a collector or museum curator almost invariably prefers a "new species" to a specimen which might lead to a clearer understanding of others already in the collection. Again, in most museums two or three shells, for instance, are considered to amply represent a species. When one has only a few examples under examination it is a fairly simple matter to assign these to so-called species; but the task becomes very different when one comes to deal with a large series, particularly if the specimens are from different localities. In all groups the range of specific variability is very much greater than will be admitted by those who confine their attention solely to museum specimens: in the case of the marine Mollusca, it is often quite easy to select from a large gathering of a single species two or more series which will readily pass as distinct species if the intermediate forms are suppressed. In the past, many "species" have been thus formed; and, if rumour speaks truly, this has sometimes been done quite knowingly, the connecting forms having been carefully destroyed; though more generally it has arisen inadvertently through the study of insufficient material. Again, a museum series, in addition to demonstrating the range of variation of a form, should also illustrate its life-history; but only too frequently an immature individual is regarded by the collector as a "bad specimen" and thrown away as valueless.

Exact Localities.—The most important consideration in a collection is that every specimen shall be accurately localised, and the more minutely the exact locality has been recorded the more valuable will the specimen be for study. At the present day, perhaps, few collectors are satisfied with such records as "Australia" or "America," but such scarcely less vague ones as "S. Africa," "W. Indies," &c., are to be commonly met with; and specimens with inexact localities, or without any record at all, abound in our museums. One unsatisfactory feature about specimens purchased from dealers is that there is a temptation for the dealer to suppress the true origin of his specimens.

Those whose knowledge of species has been derived mainly from museum specimens seldom realise how greatly these species often vary in relation to their environment. Thus, in the case of the marine Mollusca, specimens obtained from the sandy portions of a shore will frequently differ perceptibly from others of the same species collected on the neighbouring rocks or mud. By keeping the series from different stations distinct, the collector will often be surprised at the considerable local variation which his specimens will manifest.

Fossil and Recent Forms.—The treatment of palæontology as a distinct science is one of the greatest obstacles in the way of a proper appreciation of the problems of taxonomy. In most museums, as in our own National collection, the fossil forms of a group are widely removed from their recent allies; and the not unnatural result is that writers on existing species of, say, the Mollusca, seldom make even the slightest reference to fossil members of the group. A true knowledge of the relationships of the living members of any group *can* only be attainable by the study of those forms which have preceded them in the process of evolution; and this research will be greatly simplified when recent and fossil forms can be examined side by side. The comparison of recent specimens with the closely related subfossil ones from the same locality and elsewhere is of most particular importance, but is as yet seldom possible.

The Condition of Specimens.—Among conchologists, and in this respect they are almost the only sinners, insufficient attention is generally paid to the condition of the specimens. The collector of shells too often prefers to gather up the miscellaneous débris of a "shell beach" rather than search for living examples, and unfortunately he is in the habit of founding "species" upon material so obtained. A very large percentage of Molluscan species has been based upon single, dead and unlocalised specimens: what wonder that so many of their names are absolutely worthless?

"*Faking*" *Specimens.*—Any interference with the natural

appearance of a specimen is to be most strongly deprecated, unless, indeed, this has been deliberately undertaken for the express purpose of demonstrating some particular structural feature; yet many collectors are in the habit of making their specimens "look pretty." The conchologist removes the periostracum from his shells, treats them with acid or oil, and conceals any imperfection by aid of a file; the entomologist is said to be not above patching a damaged insect with parts taken from another specimen (not necessarily of the same species); and corals are occasionally provided with artificial bases of plaster of Paris.

The practice in vogue in many museums of mounting small specimens upon tablets is an exceedingly bad one, since it greatly restricts any critical examination; moreover, the specimens are liable to be injured by the cement used.

Collecting a Representative Series of Specimens.—As has been pointed out, scientific research necessitates the examination of large series of specimens exactly representing the form as it occurs at the particular station where the specimens were collected. The field naturalist will most readily ensure that a series shall conform to this condition by collecting every specimen of the form in question which is observed during a certain period of work—five minutes, an hour, a month, according to its abundance and variability. And, in order that small local variations may be rendered evident, the area over which the series is collected must be a small one. If now the whole gathering thus obtained is kept *intact* and unmixed with specimens collected on other occasions or at different stations, it may safely be regarded as fairly representing the species as it occurred at that particular time and place; and it will form a satisfactory basis for comparison with similar series gathered elsewhere and at other seasons. It will probably be urged that this system of collecting is impracticable, as it will entail greater cabinet space. Granted that it may necessitate the provision of more storage room, but is not the usefulness of a collection the only excuse for its formation? And if more space is required it must be provided. However, this objection is not nearly so serious as might be imagined; it is by no means necessary or even desirable that enormous series of specimens should be displayed for exhibition in museum cases or cabinets; all that is required is that they should be stored in such a way as to be easily accessible when wanted for study. Thus in most cabinets much space is occupied by cotton-wool which could readily be filled with specimens without in the least adding to the bulk of the collection. In any case, whatever difficulties may be encountered they will have to be overcome, as only when large series of carefully localised specimens from numerous stations are gathered together in our museums and private collections will it be possible for any really scientific taxonomic work to be accomplished. Until this material is available it is useless to argue over rules of nomenclature and such like, as no satisfactory answer can yet be given to the fundamental question, "What is a species?" S. PACE.

Variations of Atmospheric Electricity.

I ENCLOSE a photograph of the tracings, recording the atmospheric electricity disturbances from January 4 to February 15 inclusive. The records are obtained in the following manner: Two antennæ are used, one vertical 20 metres in length, its lower extremity connected to coherer. The other, 47 metres long, consisting of an ascending vertical portion of 20 metres, also connected below with same pole of coherer, a horizontal portion of 7 metres, and a descending vertical portion of 20 metres, the whole being the shape of an inverted U, going up one side of house, across the top and down the other side. These two antennæ are carefully insulated. The other pole of coherer is connected to earth, in this case to the bottom of a deep well. The coherer closes the circuit of a relay, which in its turn closes the circuit of two electro-magnets, one of which draws up the style and so records a stroke on the revolving drum; the other sets a clockwork apparatus in movement which strikes coherer and so decoheres. The receiver is situated on a hill, overlooking the neighbouring country.

The disturbances seem at times to recur about the same time on successive days, or sometimes after an interval of a day or two. For instance, the first two on the 4th and the first two on the 9th seem to have some connection. Again, the second pair on the 9th seem identical with the first pair on the 10th.

Taking the central group on the 9th, 10th, 12th, 14th, it might be subdivided into two groups, commencing on the 9th with two in each group, reaching its maximum on the 10th, five and seven, and on the 12th reduced to one in each group, finally, on the 14th, only one remaining in the stronger group, that is the one with a maximum of seven.

On February 13 there was one disturbance, on February 14 two, the first of which was at identically the same time as the one of the previous day. It would be interesting to compare the records of several receivers and see how far-reaching these disturbances are, or whether they are purely local phenomena. For this purpose two more receiving stations are shortly to be fitted up in this department. During the period covered by these records there have been no visible or audible signs of thunderstorms, and on many occasions the sky was cloudless, barometer high, thermometer low—28° F. to 36° F.—during the last eight days of February, when there could have been no storms within several hundred miles. E. PELLEW.

The Selborne Yew-tree.

GILBERT WHITE, in his "Antiquities of Selborne," Chap. v. (Chandos Classics Edition) mentions a male yew growing in the churchyard. He believed it to be some centuries old and states its girth as 23 ft. This afternoon I have, with Mr. Lewis Eynon, remeasured the trunk and find it to be 25 ft. 6 in. The stem of this magnificent tree is squat and rather bulging, and as White mentions its girth as something extraordinary, it is to be presumed that his measurement was made at the point of maximum diameter—about four feet from the ground. This is the height at which our figure was obtained, and we used a steel tape taken right round without regarding irregularities of surface. The increase in girth will be seen to correspond to a radial growth of 4·7 in. in the 120 years or so since White's time. I know not whether recent measurements of this tree have been published, but the fact seems worthy of record.

INJURIOUS CONSTITUENTS IN POTABLE SPIRITS.

AN interesting communication is just to hand, by Sir Lauder Brunton and Dr. Tunnicliffe, upon "Certain apparently injurious constituents of potable spirits." Its appearance now is certainly opportune, since, whatever else we may be interested in, alcoholic beverages are certainly attracting a deal of public attention at the present time. It is further, if not a relief, certainly a change, to learn that something else in alcoholic drinks besides arsenic and selenium may be the cause of mischief, and their removal advantageous. Our mentation just now is rather apt to be over-arsenicated; moreover, from the point of the consumer, the impurities discussed by these workers certainly seem to have one important advantage over arsenic, in that they can be completely removed—that is, removed to the satisfaction of the chemist as well as to that of the pharmacologist.

The subject of whiskey, with which the above monograph is concerned almost entirely, has not received very much attention at the hands of chemists, pharmacologists or dietetic experts, since the publication, in 1891, of the report of the select Committee on British and Foreign Spirits. This Committee directed itself mainly to the question whether compulsory bonding, as practised in Canada, should be adopted in this country, and also whether any restrictions should be placed upon blending, as by, for instance, limiting the name whiskey to the product made from malt, or malt and grain, in a so-called pot-still. The result of the Committee, so far as legislation was concerned, was nil. In the course of the inquiry, however, many interesting pharmacological facts came out, and the present work must be looked upon as a continuation of what may be termed the pharmacology of whiskey. Readers who are interested in the subject are strongly recommended to consult the Blue Book, which contains a mass of most interesting and important information.

Certainly until the appearance of this report, and by many even to-day, fusel oil is regarded as par excellence the injurious constituent of whiskey. This substance, which is a mixture of varying proportions, according to the spirit, of butylic, propylic and amylic alcohols, has apparently been maligned, and is not, at any rate in the proportion in which it occurs in ordinary potable spirits, a source of much danger to the public health. The chief other impurities touched upon at this inquiry were furfural and aldehydes other than furfural. At that time very little was known concerning the action of furfural or the aldehydes, and it is especially in this connection that the monograph before us is of interest.

Although there can be no doubt that it is the ethyl alcohol that causes alcoholic intoxication, it appears that the actual way in which one gets drunk, or gets sober after being drunk, depends largely upon the quality of the liquor partaken of. One of the most important factors in determining the quality is the content of the beverage in question in aldehydes, including furfural, another its content in certain volatile bases.

The source of furfural in the manufacture of whiskey is a class of substances known as pentosans; these are derived from the cellulose of the grain husks, and under the influence of heat, in the presence of acids, are in the wash still converted into furfural. Furfural is present in all pot-still whiskeys, and also obviously to a less extent in those patent still whiskeys which are blended with the real pot-still products to give them the taste of whiskey. Any one can apparently demonstrate for himself quite simply the presence of furfural in whiskey. It is simply necessary to dilute the whiskey and to add to it a few drops of an aniline acetate solution; almost immediately the whiskey becomes rose-coloured and later deep rose, changing to light purple according to the quantity of furfural present.

In addition to furfural there are also present in whiskey other aldehydes. Speaking generally, these bodies are poisonous, or at least irritating; they are for the most part converted in the body into the corresponding acid, and thus tend to diminish the alkalinity of the blood. This individual point is not without interest in that, according to most physicians, any cause tending to render the blood less alkaline favours the occurrence of gouty deposits in the joints.

The experimental inquiry concerns itself more especially with the action of furfural upon animals and man. This substance, according to Sir Lauder Brunton and Dr. Tunnicliffe, gives rise to paralysis of the voluntary muscles, and later to clonic and tonic convulsions. An odd point about these symptoms is their transient nature; immediately after the injection of the drug the animal would fall down completely paralysed, its tongue and lips would become bluish and its breathing slow and convulsive, at other times irregular and rapid; convulsions would then appear, vomiting would occur, and then the animal would begin to recover, being at first dazed but becoming rapidly normal. Two human subjects who were bold enough to take this apparently active poison in the same dose got bad throbbing headache after it which lasted the rest of the day. This latter result brings us to what, from the practical standpoint, is the most interesting part of the research.

We believe it will be generally admitted that one of the commonest results of too free potations in the human subject is a bad throbbing headache, and it appears that the alcohol itself is only partly to blame for this disagreeable sequela. The aldehydes generally, and furfural particularly, play a very active part in the production of these headaches. This appears to be one reason why one is less liable to get a headache after old whiskey, for instance, than after new, or, speaking more correctly, relatively new. One of the effects of maturation upon whiskey is to diminish the amount of furfural and aldehydes which it contains. This effect of maturation can apparently be effected by another means, viz., by distillation of the fresh spirit or of the low wines with phenylhydrazine-sulphonate. By this means the authors were able to obtain an aldehyde-free whiskey, and to watch the effect of it upon animals, comparing it with that of the same spirit before distillation. Their results are certainly interesting. They found that recovery from profound alcoholic, or rather whiskey, poisoning was distinctly different in the two cases. In the case of the original spirit, the animal, during the transition stage from drunkenness to sobriety, was restless, wandering from one part of the laboratory to another, and seemed, generally speaking, remarkably uncomfortable. Even when the gross symptoms of alcoholic poisoning had passed off the animal did not behave normally for some time; it refused food offered to it, and showed marked signs of bad temper. These secondary symptoms were entirely absent in the case of the aldehyde free spirit. When the animal was sober it appeared perfectly normal, and if offered food took it apparently with relish.

These symptoms, which cannot fail to remind one of the so-called "Katzen-jammer" of the German student, are, oddly enough, most markedly relieved by precisely those substances which contain chemical groups capable of combining with and rendering innocuous these same aldehydes. The most general substance used in this connection is either ammonia itself or some compound containing amido (NH_2) groups. The action of all morning "pick-me-ups," from the student's red-herring to the viveur's effervescing citrate of caffeine, is apparently explainable upon this hypothesis, viz., that they neutralise the alhedyde constituents of the potable spirits.

THE ORIENTATION OF GREEK TEMPLES.

A PAPER, "Some Additional Notes on the Orientation of Greek Temples," an abstract of which was read before the Royal Society on February 14, gave an account of six Grecian temples of which the orientation had been examined or re-examined during the spring of 1900. The chief observations and results described in the paper may be stated as follows:—

(1) The grotto sacred to Apollo on Mt. Cynthus, in the isle of Delos, was interesting as being not improbably the very earliest existing structure of a religious character on Greek soil. The orientation seems, as usual, to have been connected with a zodiacal star, α Libræ, and the date of the formation of the grotto derived from this is about 1530 B.C. The original foundation of temples in Greece on some other sites are, indeed, more ancient than this; but it is presumed, and in a good many cases can be clearly established, that in those cases what can be now seen and measured is that which remains of reconstructions following the same lines as the earlier works. But this grotto at Delos, the sides of which are formed by the natural rock, and the roof and doorway only are artificial, is probably the very shrine alluded to by Virgil as already ancient at the time of the Trojan war (*Templa dei saxo venerabar structa vetusto*, Æn. iii. 84).

(2) At Delphi, where the clearance of the site by the French archæologists gave a better opportunity of examining the celebrated temple of Apollo, there is evidence of a change of orientation, one, evidently the more ancient, having the angle 231° 18′, the other 227° 8′. These are the angles of the axis when looking east, measured from the south point round by west. The site is very peculiar, being surrounded by mountains. The sun must have illuminated the sanctuary through an opening on the flank, as was the case at Bassæ, also dedicated to Apollo;

and there are only two dips between the mountains where the sunrise could have properly represented the early dawn. One of these has for amplitude $-7° 42'$ E., the other $-23° 16'$ E. The latter, taken with the earlier orientation, and the bright star ϵ Canis Majoris setting near the western axis, where the local horizon is favourable, suggests 950 B.C. as the date of the foundation. The sunrise at the $7° 42'$ point, and the sufficiently bright star β Lupi, setting also near the western axis of the more recent temple, offers the date of 580 B.C., but this would have been the predecessor of the structure which now occupies the site. It is known that the temple must have been several times rebuilt, and many stones of a previous temple, or temples, are found in the existing foundations.

At Syracuse it was found necessary to reconsider the orientation date (given in a former paper published in 1897) of the temple which has been attributed to Diana, but which is now known from an inscription to have been dedicated to Apollo. Of this temple, both the style of the architecture and the shape of the letters of the inscription above mentioned show that the date 450 B.C. given in the paper referred to, the orientation having been derived from the axis, is too late; and that the alternative date, derived from the northern limit of the eastern opening, which in this case can be obtained with accuracy, should be taken instead. The date, so altered, becomes 700 B.C., which is thirty-four years subsequent to the Hellenic foundation of the city.

N.B.—In Greek temples the question whether the sunrise entered upon the line of the axis or on the northern limit of the eastern opening has generally to be taken into consideration and decided upon archæological grounds. This results, in the majority of cases, in favour of the axis; but in an important minority—notably at Athens—the other has to be chosen.

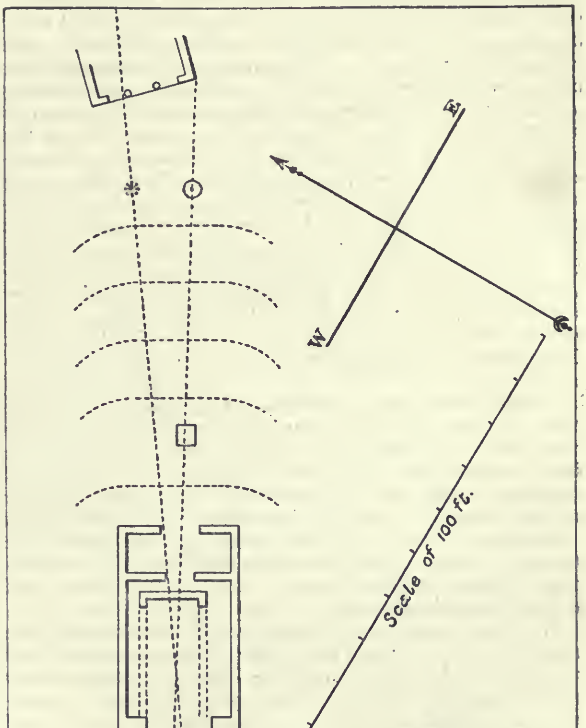
(3) In the paper an argument is drawn from the orientation of the foundations of a small temple lately discovered, adjoining the famous theatre at Taormina, that the theatre itself was that of the early and populous city of Naxos, which occupied the sea-coast at about 800 feet immediately below it; and not the work of the much later town of Taurominium, from which Taormina derives its name. Naxos was utterly destroyed by the Syracusans about 400 B.C.

(4) The most interesting example, however, is from another Sicilian temple lately unearthed at Selinus. Of this temple I found the orientation of the eastern axis to be $30° 22'$ north amplitude, which at once suggests a solar temple arranged for the summer solstice, which for a level site and for the date in question should be $30° 35'$. But the temple's site is near the bottom of a valley; and the sun would have to gain an altitude of rather more than two and a half degrees before it could shine into the temple, and then the amplitude required would be $28° 17'$. Thus, apart from what may be derived from the plan of the temple itself, the orientation theory would seem to show to a disadvantage.

The plan of the temple, however, appears to give the solution of the difficulty. It will be seen on examination of the accompanying figure that about 130 feet distant from the sanctuary there was a portico, *i.e.* the propylæa of entrance to the temple enclosure. One of two dotted straight lines drawn from this portico, namely, that which proceeds from its S.W. corner, indicates the direction of the first beam of sunrise as it rose at the summer solstice over the local horizon, about the middle of the sixth century B.C.; but it will be seen that whilst it passes centrally through the doorway it falls obliquely and excentrically upon the western internal wall of the temple, the amplitude of this line being $+28° 17'$ E.; but it will be also observed that it *does* fall centrally upon the western internal wall of a *naos* constructed within the flank walls of the temple. The square object which the line intersects before it reaches the temple is an altar, itself of no great height, and on lower ground, and which therefore interposed no obstruction to the solar rays reaching the sanctuary. The difference of level between the floor of the temple and that of the propylæa is about 18 feet. The warning star β Geminorum, which would have been heliacal—that is, just visible before extinction—about an hour before sunrise, and the direction of which is represented by the other straight dotted line, would have been well seen over the roof of the propylæa, the height of which, as known from architectural fragments, would not have exceeded 23 feet, and the star would have overtopped this by about 2°.

The explanation, by help of the plan, of the apparent misfit of the orientation is as follows:—

Presumably the angle upon which the lines of the



SELINUS

Newly discovered Temple

temple were set out was taken from data obtained on some platform which had a level horizon, and the building was considerably advanced before the actual solstice came round and showed the error that had been made.

To meet the difficulty, a *naos* was constructed within the flank walls, but hugging the northern one; so that the first beam of sunrise coming through the centre of the eastern aperture, at the local amplitude of $+28° 17'$ E., might shine in centrally upon the statue of the deity; and for this a pedestal was provided a little northwards of the centre of the niche which had been previously formed for it. We may notice also that the south-west angle of the propylæa is so placed as to keep exactly clear of the point of sunrise. F. C. PENROSE.

PILOT CHARTS.

FROM the popular and astrological point of view, meteorology is as old as the oldest of the canonical writings; but as a scientific study it may truly be said to belong wholly to the great Victorian era of scientific development. It was only in the 'thirties of last century that Redfield and Reid—the former in America, the latter in the West Indies—set about the patient study of the vagaries of storms, and discovered that these meteors were, like everything else in Nature, subject to natural laws. By the middle of the nineteenth century the progress made by the early pioneers was such that Maury felt justified in utilising the results in the preparation of his pilot charts for mariners all the world over. Maury's charts were certainly not perfect; fifty years afterwards many would, no doubt, regard them as a confused mass of information which would weary the most persistent student in an endeavour to unravel them; but useless as they seemed to be at first sight, they have proved to be the pioneers of the most useful works published in the interest of navigators. It has long been recognised that the sailor wants, in addition to ponderous tomes dealing minutely with every phase of navigation, handy summaries of the more essential features of everyday life on the ocean, arranged in a simple manner for immediate reference. The Board of Trade published charts containing varied information forty-five years ago, and the Hydrographic Department issued its well-known quarterly pilot charts more than thirty years ago. Other nations, France, Holland, Denmark, &c., have devoted much attention to the necessity of keeping mariners acquainted with all the latest information relating to the meteorology of the various oceans. For many years past the Hydrographic Department at Washington has left no stone unturned to popularise its Pilot Chart of the North Atlantic, and of late years it has been perfecting a similar work for the North Pacific. In the meantime, Germany has not only been increasing her naval strength, but her mercantile fleet is daily becoming more and more important, and the latest evidence of this is found in the January number of the *Annalen der Hydrographie und Maritimen Meteorologie*, in which Dr. Neumayer announces the issue, by the Deutsche Seewarte at Hamburg, of a monthly chart for the Atlantic, mainly for the steamships engaged in the Transatlantic trade.

But the importance of the question of keeping the mariner in touch with the progress of meteorology has not escaped the attention of the English authorities, for the Meteorological Council has just distributed a specimen monthly pilot chart of the North Atlantic and Mediterranean for the month of January, it having been decided to commence a series of such publications in April. In the compilation of the charts, advantage is to be taken not only of information in the possession of our own Hydrographic and Meteorological Offices, but also of any suitable facts published by similar establishments in other countries. Just as we are certain that the atmospheric conditions during winter are different in various ways from those which obtain in summer, so we may conclude that between the extremes there are, on the average, more or less gradual changes in the controlling features, and, therefore, we must expect that every month in the year has its own individualities, which are not exactly in agreement with even those of neighbouring months. To be of real use to the navigator, then, information should, as far as possible, be sorted out into its principal monthly features, and this is to be the aim of the Marine Department of the Meteorological Office under Commander Hepworth, R.N.R., the superintendent. Each ocean area of 5° of latitude by 5° of longitude contains a wind-rose showing the prevailing winds, some of the less frequent winds, and the frequency of calms, a simple method being adopted to indicate the mean strength of the wind, whether light, moderate, or gale. The normal limits of the Trades; the sailing routes recommended to and from the Equator; the steamship routes to and from America; the mean paths followed by cyclonic areas; the region in which gales exceed 10 per cent. of the wind observations; the localities affected by fog; and the ice limits about Newfoundland are laid down. A feature of as great interest to the theoretical physicist as to the practical sailor will be the ocean currents for each separate month, based upon observations covering a period of sixty-five years. Until the Admiralty and Meteorological Office recently published a selection of the currents in representative months, the scientific world had to be content with studying the circulation of the waters from a chart representing the annual results only. There will now be an opportunity for a much closer study, as the monthly winds and currents are given together in the same sea-room, while the distribution of atmospheric pressure for the same month is given, with that of the air and of the sea temperature, in an inset chart, and all three subjects must be considered as inseparable when investigating ocean currents. Two other inset charts represent south-westerly and westerly types of weather over Western Europe. In addition to the foregoing pictorial method of displaying the facts, a considerable amount of valuable information is conveyed in descriptive letterpress on all available spaces, directing the navigator's attention to the dangers associated with making the Spanish coast, to the Harmattan winds of West Africa, the Northers of the Gulf of Mexico, the Mediterranean sirocco and other winds; to treacherous inshore currents; to the difficulties arising from the low-lying haze and the great refraction along the west coast of Africa; to the rollers breaking on the South American coast, from Trinidad to Guiana; and advice is given as to the best routes for crossing the Equator. An interesting article is devoted to Atlantic storm systems, showing how the mariner must combine his wind and barometer observations when he wants to ascertain the behaviour of the disturbance which may be affecting his ship, the problem being much more complicated than is generally supposed, and more particularly in this age of swift steamships, which may be travelling faster than a cyclone, so that the experiences on a liner travelling eastward through a storm would be largely different from those on another meeting it going westward. Everything depends upon the particular circumstances, and with the aid of these notes and an intelligent interpretation of them, officers should be able to have a much better knowledge of the cyclonic areas through which they so frequently have to steer. For many reasons, the new pilot charts deserve to have a long and successful career.

MALARIA AND ITS PREVENTION.

SINCE the work of Laveran (1880) proved malaria to be a fever caused by the invasion of the blood by minute animal organisms, steady progress has been made in the work of probing and elucidating the etiology and pathology of this dreadful scourge.

The extent of its ravages was—and, unfortunately, still is—appalling, and the recognition of this fact has impelled many eminent scientific men to direct their best efforts towards solving the problems which have been facing us for the last twenty years, and which were the natural offspring of Laveran's discoveries.

English, Italian and German workers have competed with each other in the race and shown unprecedented keenness and enthusiasm; of their work an immense bibliography remains as a monument to-day. In America, too, has been done some of the very best work.

At the present time, however, though our knowledge of the Hæmamœbidæ has so much increased and though their pathological significance is now more clearly defined, yet we cannot say certainly that all the species which invade man have been identified.

In England we group all malaria parasites under three heads :—

(1) *Haemamoeba malariae*, the parasite of Quartan fever.

(2) *Haemamoeba vivax*, that of Tertian fever.

(3) *Haemamoeba precox*, that of Quotidian or æstivo-autumnal fever.

But in Italy Grassi states positively that he has observed a fourth species, which he names *Haemamoeba immaculata*. This species is without pigment and has been accepted by Marchiafava and Bignami, but our knowledge of the facts is still somewhat limited. In West Africa the first expedition which went out to investigate malaria was inclined to divide *H. vivax* into two distinct species differing in the colour of their pigment, one with fine brown and the other with fine black granules. Furthermore, it has been suggested that *H. precox* may be also split into two or more distinct species.

On these points we must await the results of patient investigations now pending.

For many years after the inseparable association of the Hæmamœbidæ with malaria had been demonstrated, the means whereby they could enter the blood and attack the corpuscles was unknown. But at last the work of Ross in India (with which Manson must ever be associated) enabled us to see light. King (1841) had suspected that mosquitoes were a factor in malarial infection, as also had Laveran ; but Ross led us, by his researches in the life-history of *H. relicta* (the parasite of birds), from mere hypothesis to fact. Confirmation was soon forthcoming in Italy, a country where the prevention of malaria is of great economic importance ; and later expeditions were dispatched by the Liverpool School of Tropical Medicine, the Royal Society and the German Government to various malarial districts, to thresh out the whole question and to evolve, if possible, some practical method or methods of prophylaxis.

Valuable experiments, too, were made in the Roman Campagna last year by the London School of Tropical Medicine, which afforded valuable confirmation of the views advanced by previous expeditions. More recently, too, an expedition from Liverpool has returned after making a complete survey of the lower reaches of the Niger, with the result that previous observations have been confirmed and further additions to our knowledge made.

Now we know, with a certainty rarely attained in medical matters, that malaria, instead of being inhaled with the night air as a noxious miasm from marshy countries or ingested with water, as was at one time suggested, is caused by the direct injection of animal parasites into the blood by mosquitoes previously infected by some human being suffering from the fever.

Careful microscopic work has shown that the Hæmamœbidæ of human malaria are parasitic not only in man but also in certain mosquitoes.

The parasites have two phases in their cycle of development, and need a different host for the completion of each phase, that is to say, that like many other well-known parasitic organisms, they exhibit "alternation of generation," in which man is the "intermediary" and mosquito the "definitive" host.

But it has been proved that all mosquitoes are not hospitable to the hæmamœbidæ of malaria. One genus only—Anopheles—has so far been convicted, though Culex has been subjected to an equally searching cross-examination.

Although Anopheles, as compared with Culex, is a small genus with a comparatively limited distribution, yet all its species have not been proved hospitable.

In West Africa *A. Costalis* and *A. funestus*, in British Central Africa *A. funestus*, in the West Indies *A. Costalis* (?), in Italy *A. Maculipennis*, are the species chiefly concerned as agents of transmission.

With the information at present obtainable it must, therefore, not be too hastily concluded that the whole genus Anopheles is hospitable to the parasites, but I venture to say that it may now fairly be assumed, on the other hand, that no species of Culex ever conveys the human parasites, though this genus is chiefly concerned as definitive host of the avian hæmamœbidæ.

White men who have travelled in the tropics say, assuming what you teach about the parasitic nature of malaria and the part played by mosquitoes to be the truth, there remains the question as to where the mosquitoes originally became infected. This was for a time a mystery, but the recent work of Koch in Java and Stephens and Christophers in West Africa has afforded an explanation. These observers independently discovered that though adult natives suffered little or nothing from malaria, yet their children from earliest infancy exhibited great numbers of parasites in their blood, though, like their parents, they rarely showed marked symptoms of infection. The blood of 80 to 90 per cent. of native children in some districts has been shown to contain parasites, and it has been noticed that these varied in number inversely as the number of years of life ; that is to say, evidence of parasitic invasion decreased as the children grew to manhood, and gradually a condition of partial immunity was attained.

Similar instances of acquired immunity are occasionally seen among white men who have lived many years in malarious countries. The mechanism of this immunity is as yet unknown.

It appears, therefore, certain that the prime source of mosquito infection is the native children, who, though not indifferent to mosquito bites, appear to view their ravages with equanimity. It follows, then, that the proximity of native habitations is a constant menace to the health of white men provided that the necessary connecting link—Anopheles—is also present. In considering the best means of prophylaxis, it will be seen that important deductions have been drawn from these facts.

The prime cause of malaria being known, its method of invasion having been satisfactorily demonstrated and the official seal of scientific approval to these facts having been obtained in Lord Lister's recent address to the Royal Society, it remains now to apply our knowledge in a practical way, so as to evolve some method or methods of prophylaxis and thereby crown a piece of scientific work as far reaching in its power to benefit the whole human race as any of those brilliant discoveries which have made the Victorian age conspicuous above all others.

And that this is not the language of exaggeration is readily seen when one considers the enormous tale of deaths caused annually throughout the world by malaria, and when one realises how much the control and development of new territory are arrested by the constant invalidism of Government officials, medical officers and traders in tropical climates, where it is constantly necessary to employ two men to do the work of one.

This latter point will appeal specially to those who recognise that the British Empire is now world-wide and tending to still further extend its borders.

During the last two years various authorities on paludism abroad, and members of the various expeditions from England, have made suggestions and recommendations as to the prophylactic measures which should be taken in consequence of the recent additions to our knowledge.

Some have advocated wholesale destruction of

mosquitoes by surface drainage and by the treatment of their breeding puddles with substances fatal to their development; others have suggested the careful and more extensive use of mosquito-proof curtains and blinds, &c.; while one distinguished authority holds that the continuous administration of quinine is likely to give the best results.

This apparent difference of opinion has afforded an opportunity for unbelievers to scoff; but there exists, notwithstanding differences of opinion as to detail, an entire unanimity as to the principles on which we should work.

With our present knowledge we are not justified in saying that any one alone of the measures mentioned above is of preeminent value, for all are not applicable to the same district, nor is the application of one method alone likely to prove sufficient.

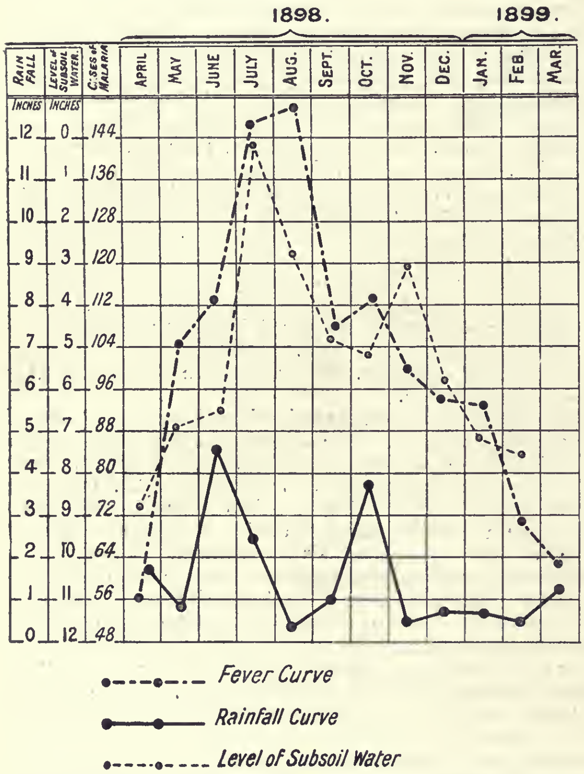


FIG. 1.—Chart showing relation of incidence of fever to rainfall and to level of subsoil water. (From figures supplied by Dr. Strachan, P.M.O. Lagos.)

It is in a due application of all these methods, in so far as each is practicable and suited to the district under consideration, that the truest salvation will be found.

In support of this view I would mention the conditions of rainfall and geological formation which obtain at Sierra Leone, Accra (Gold Coast) and Lagos (Fig. 1). In the first, surface drainage is possible and could not fail to somewhat reduce the ravages of malaria, but in the last-named colony any system of drainage is impossible; the town is built on a sandy island which has the general form of a saucer; here some other method must be considered. At Accra, on the other hand, the rainfall is so small and the soil so absorbent that there are no puddles or marshy lands which need draining. Here, again, some method other than drainage must be sought for.

Since the days of Empedocles of Agrigento (B.C. 500) the efficacy of surface drainage has been known and, where practicable, is doubtless one of the surest methods. But in districts unsuitable from any cause, the application of larvicidal substances (petroleum, tar, lime, &c.) has been suggested; but, so far as experiments go, the effect of such applications has proved too transient to be of much value. The essential point is to avoid being bitten by infected mosquitoes by night and also by day, for, notwithstanding statements to the contrary, I have repeatedly noticed Anopheles gorging themselves in full daylight, though no doubt their habits are chiefly nocturnal.

For this purpose the constant use of mosquito curtains of a proper kind is essential. Unfortunately, since familiarity breeds contempt, it is only too frequently that one finds in the tropics curtains of an utterly useless kind being used; either they are torn or the mesh is too large, or by their arrangement the free ingress of mosquitoes is possible.

They are best fixed on four posts at the four corners of the bed, and as the netting descends around the bed it should be tucked in under the mattress. The enclosed space should be of sufficient size to allow a certain freedom of movement during sleep, so that the danger of coming into contact with the netting is impossible.

More effectual, however, is the employment of wire gauze blinds to windows and doors, so that bedrooms and houses generally are kept entirely free from mosquitoes.

Celli recommends that windows should be protected by wire netting the meshes of which measure from 1 to 1·5 mm. square, and that all doors opening exteriorly should be protected by a cage of similar netting, so as to oppose two screens to the ingress of mosquitoes (see Fig. 2). He further suggests that to facilitate the capture of any stray mosquitoes all walls should be bare and painted white, and that trees should not be allowed to grow near dwellings, as they afford a retreat in which mosquitoes may hide. Experiments carried out in the Roman Campagna have proved that these and similar devices have been sufficient to protect from fever for considerable periods; but it is to be feared that unless unceasing vigilance be exercised all such precautions may prove ineffective, and one mistake may render them entirely abortive.

We need yet, however, further information as to the habits of mosquitoes. We do not yet know certainly how far they are able to travel, or at what height can they raise themselves from the earth. On these and many other points in the bionomics of Anopheles our information is very scanty. Giles' recent work on the Culicidæ has brought together practically all we know; but workers in many distant fields find that the habits of mosquitoes are liable to vary according as local conditions are suitable or the reverse; they are, it would seem, capable of a certain measure of adaptability to their environment.

All patients suffering from fever should be specially protected, for now we know that where malaria and Anopheles co-exist the fever is infectious; in consequence of the transmission power of the mosquitoes a fever patient is a source of danger to all his neighbours.

In the matter of clothing some precautions can be taken, such as the wearing of proper mosquito-proof boots and stockings. Mosquitoes are specially fond of the shades under a dining-table, where they may pursue their depredations unchecked.

The continuous use of quinine, though backed by such great names as Koch and Manson, is open to many objections, and is a method of prophylaxis unlikely, alone, to attain such great results as the former evidently expects.

Preeminent above all other methods of prevention stands *segregation*, advocated first by the first expedition to West Africa, and since supported so strongly by the researches of Koch and in the published work of the Royal Society Commission.

Native habitations have already been referred to as the source from which Anopheles obtains its parasites; native huts, ill-ventilated and overcrowded, are the hotbed in which the Hæmamœbidæ luxuriate.

In tropical countries Europeans pitch their temporary camps, and often live permanently, within a few yards of such native hovels; given, then, a full supply of Anopheles and a swarm of native children, 80 per cent. of whom are infected with Hæmamœbidæ, it is not surprising, with our present knowledge, that an epidemic of malaria soon starts among the white men.

The pitching of camps near native villages, or living in close proximity to native huts, is flying in the face of all recent scientific research, and suicidal in its results. This cannot be too often nor too emphatically reiterated.

R. FIELDING-OULD.

THE NEW STAR IN PERSEUS.

THE HARVARD OBSERVATIONS.

PROF. PICKERING, the Director of the Harvard College Observatory, in a *Circular* No. 56, has detailed the observations of the new star made there soon after its discovery by Dr. Anderson. This *Circular* we print *in extenso*:—

The cable message announcing the discovery of a new star in the constellation Perseus, by the Rev. T. D. Anderson, was received at the Observatory early in the evening of February 22, 1901. Owing to clouds, the new star was only occasionally visible, and twice it was necessary to cover the instruments on account of falling snow. During the intervals, however, various observations were made, which have a value owing to their early date. Numerous comparisons by Miss Cannon, with α Aurigæ, magnitude 0·21, α Orionis, magnitude 0·92, and α Tauri, magnitude 1·06, showed that the magnitude of the star was about 0·9. Photometric comparisons, by Prof. Wendell with the 15-inch telescope, of the Nova with the star +43°·732, magnitude 7·25, at 14h. 0m. and at 17h. 25m., Greenwich Mean Time, gave the magnitudes 0·35 and 0·39 respectively.

Meanwhile, an examination was being made, by Mrs. Fleming, of the photographs of the region obtained here earlier in the month, with the various instruments. Although photographs are taken with the transit photometer throughout every clear night, yet owing to twilight they cannot be taken as early in the evening as this star culminates. Fortunately, for some weeks the work of the transit photometer, which only photographs objects near the meridian, has been supplemented by photographs with Cooke and Ross-Zeiss Anastigmat lenses. With these instruments an attempt is made to cover the entire sky, both east and west of the meridian, at short intervals. The completeness with which this has been done is shown by the fact that we have photographs of the region of the Nova with the Cooke lens on February 8, 18 and 19, and with the Ross-Zeiss lens on February 2, 6, 18 and 19. The photograph taken with the Cooke lens on February 19 had an exposure of 66m., beginning at 11h. 18m. Greenwich Mean Time. While this photograph showed not only the faintest stars contained in the Durchmusterung, but also stars as faint as the eleventh magnitude, no trace of the Nova was seen. This result was confirmed by the other plates mentioned above. A general examination of the large number of earlier plates of this region did not seem to be necessary. Plates taken with the 8-inch Bache telescope as early as November 6, November 8 and December 12, 1887, fail to show the Nova, although the spectra of stars as faint as the eighth magnitude are clearly visible on all, and those of the ninth magnitude on the plate taken on November 6. A photograph taken with the 24-inch Bruce telescope on October 18, 1894, with an exposure of 15m., shows no trace of this object, although stars as faint as the magnitude 12·5 are well seen.

On this same evening, February 22, eighteen photographs were taken with various instruments, under the direction of Mr. Edward S. King. They showed that, photographically, the Nova was 0·3 fainter than α Aurigæ. The general appearance of the photographic spectrum resembled that of the Orion type and was very unlike that of other new stars, in which the bright lines are the most conspicuous feature. This star had a strong continuous spectrum traversed by thirty-three dark lines. The approximate wave-lengths, as derived by Hartmann's formula from the measures of Hε, Hγ and Hβ, are given below. Each is followed by its relative intensity, and by the difference found by subtracting it from the wave-length of the corresponding line, if any, in the spectrum of β Orionis. As the lines having greater wave-length than 5000 have thus been determined by extrapolation, they may be subject to large systematic errors.

3894, 10, Hζ, −5; 3970, 20, Hε, 0; 4026, 3, 0; 4077, 2, −1; 4102, 30, Hδ, 0; 4126, 5, +2; 4151, 1, −4; 4266, 2, +1; 4341, 40, Hγ, 0; 4366, 1, +1; 4388, 2, 0; 4415, 1; 4435, 1, +3; 4470, 2, +2; 4481, 20, 0; 4510, 2, −2; 4530, 2; 4552, 2; 4572, 1; 4616, 1; 4643, 1; 4665, 3; 4714, 3, −1; 4862, 40, Hβ, 0; 4885, 2; 4922, 2, 0; 5325, 1; 5399, 1; 5431, 1; 5677, 2; 5695, 7; 5719, 5; and 5761, 1. On careful examination the lines 3970, 4102, 4341, 4481 and 4862 were seen to be bright on the edge of greater wave-length. The line 4665 was bright on the edge of shorter wave-length, or there was a bright line whose approximate wave-length was 4660. The line 4026 was not measured, but identified from its position.

FIG. 2.—Hut with mosquito cage round door, which is itself mosquito proof (as suggested by Celli). Reproduced from a photograph lent by the Sanitary Institute.

On February 23 the clouds were so dense that few observations could be made. The star appeared to be brighter and bluer than α Aurigæ and to have the approximate magnitude 0·0. The spectrum was photographed faintly and showed no marked change except that the line K, which was absent on the previous evening, was present and nearly as intense as Hε.

On February 24 it became clear soon after noon, and at 1 o'clock the Nova was seen with the 6-inch Equatorial, and also with the 2-inch finder, in strong sunlight. In the evening the magnitude, according to visual comparisons, was 0·54, from measures with the 15-inch Equatorial, 0·59, and with the meridian photometer, in strong daylight, 0·28. Photographically it was 0·4 or 0·5 fainter than α Aurigæ. The spectrum showed a remarkable change. It was traversed by numerous bright and dark bands, and closely resembled that of Nova Aurigæ. The principal lines were dark with accompanying bright

lines of somewhat greater wave-length. The bright lines accompanying K and Hϵ were reversed, and traversed by narrow, well-defined dark lines. These last lines, and one of somewhat shorter wave-length than Hβ, are the only sharply defined lines in the spectrum, all of the others being broad and hazy, and difficult to measure with accuracy.

Clouds interfered with observations on February 25, but the Nova was evidently much fainter than on the previous evening. Its magnitude from visual comparisons was 1·4, from photometric measures, 1·07. The spectrum differed slightly from that on February 24. The lines Hδ, Hγ and Hβ were also reversed and replaced by one or more narrow dark lines.

On February 26 the magnitude from visual comparisons was 1·3, from photometric measures 1·49. The changes in the spectrum were slight.

Observations of the position of the Nova were made by Mr. J. A. Dunne, with the 8-inch meridian circle, on February 23, 24 and 25, with the result for 1900·0, R.A. 3h. 24m. 24s·02, Decl. + 43° 33′ 42″·4.

It therefore appears that on and before February 19, 1901, the star was invisible, or at least fainter than the eleventh magnitude. On February 21 its magnitude was 2·7, according to Mr. Anderson. On February 22 its magnitude was 0·5, perhaps becoming a little brighter on February 23, and then diminishing, so that on February 25 its magnitude was 1·1. Its spectrum on February 22 and 23 was of the Orion type, nearly continuous, traversed by narrow dark lines. During the next twenty-four hours an extraordinary change took place, so that on February 24 the spectrum resembled that of the other Novæ. It was traversed by bright and dark bands, and the principal dark lines had accompanying bright lines of slightly greater wave-length.

During the last fourteen years, and since the general application of photography to astronomy, eight new stars are known to have appeared—Nova Persei, in 1887; Nova Aurigæ, in 1891; Nova Normæ, in 1893; Nova Carinæ, in 1895; Nova Centauri, in 1895; Nova Sagittarii, in 1898; Nova Aquilæ, in 1899; and Nova Persei, in 1901. The second and last of these, which were much brighter than the others, were found visually by Dr. Anderson. All of the others were found by Mrs. Fleming, from an examination of the Draper Memorial Photographs. Nova Aquilæ was announced by telegraph, but has not been described in these circulars. Its position for 1900 is R.A. 19h. 15m.·3, Decl. − 0° 19′. It was not seen on plates taken on November 1, 1898, and earlier, although stars of the thirteenth magnitude appeared on some of them. On April 21, 1899, it was seventh magnitude. It appears on eighteen photographs taken during that summer, and on October 27, 1899, it was tenth magnitude. In July, 1900, when it was discovered, it was about twelfth magnitude. Seven bright lines—Hζ, Hϵ, Hδ, Hγ, 4693, Hβ and the nebular line 5007—were seen in the spectrum photographed on July 3, 1899. On September 7, 1899, Hγ and a somewhat fainter line, which is probably 4959, were the only bright lines visible. On October 27, 1899, Hγ and 5007 were alone visible and bright, so that the spectrum had then become that of a gaseous nebula.

EDWARD C. PICKERING.

NOTES.

AMONG other noteworthy remarks made by speakers at the jubilee dinner of the Royal School of Mines, on March 13, was one in which Sir George Kekewich, secretary of the Board of Education, acknowledged that science must occupy a place in any wise system of education. He said, "I should like to see the day when no education can be regarded as a liberal education which excludes a knowledge of science. In addition, I should like to see no one matriculating at any University in this kingdom who does not possess some knowledge of science. Indeed, I should like to see it recognised as part of the general education of every man who has any claims to possess a liberal education." The dinner was largely attended by past and present professors and students at the College. The chair was occupied by Sir George Gabriel Stokes, and toasts were proposed and acknowledged by the chairman, Sir Kenelm Digby, Prof. J. W. Judd, Sir William Roberts-Austen, Sir George Kekewich, Sir William Huggins, Prof. Le Neve Foster, Mr. Bennett Brough, Prof. W. A. Tilden, Prof. Milne, Mr. F. W. Rudler, Prof. Bauerman, Prof. J. Perry and Mr. Hugh McNeill, the secretary. The chairman described the gradual development of the School of Mines, and referred to the humble way in which it was established. "Even still," he remarked, "it bears indications of the tentative mode of proceeding to which I have already alluded, for Sir Norman Lockyer's elaborate work in astronomical spectroscopy, so far as taking observations on the heavenly bodies is concerned, is carried on in buildings of the nature of sheds." Sir William Roberts-Austen made mention of Stokes, Playfair, Hofmann, Huxley, Tyndall, Warington Smyth, and other brilliant men of science who had been connected with the College; and other speakers showed how professors and students have played important parts in various fields of scientific and industrial activity.

THE death is announced of M. Theodore Moutard, distinguished by his contributions to geometry.

M. A. NORMAND has been elected a correspondant of the Paris Academy of Sciences, in succession to the late General Alexis de Tillo.

THE ninth triennial conference of the German Meteorological Society will be held at Stuttgart on April 1, 2 and 3, the first half of Passion week, as Easter week, the usual time of the meeting, has been set apart for the Seismological Conference at Strassburg. Hail will form one of the principal subjects for discussion.

IT has been decided to hold the seventy-third meeting of the German Association of Naturalists and Physicians at Hamburg from September 22 to 28 next. In response to many representations there has been a rearrangement of the sections, which have hitherto numbered thirty-eight, but will in future be reduced to twenty-seven, and of these sixteen will be medical sections.

IT is reported that the grave of Hippocrates has just been discovered during excavations at Larissa, in Thessaly. A Royal Commission has been sent to the place by the Greek Government to take what measures may seem advisable.

THE *British Medical Journal* announces that Dr. C. W. Daniels has been appointed superintendent and medical tutor of the London School of Tropical Medicine, in succession to Dr. D. C. Rees. Dr. Daniels served on the Royal Society's Malaria Commission in 1898 for two years, and is now seconded for a further period whilst filling his present appointment at the London School of Tropical Medicine.

THE zoological lectures of the Zoological Society of London will be delivered in the Society's meeting room this year on Thursdays April 18, May 16, June 20 and July 18 at 4.30. The first lecture will be given by Prof. C. Stewart, F.R.S., conservator at the Royal College of Surgeons, and will relate to the various devices of nature for the protection and nourishment of young fishes. The lectures are free to Fellows of the Society.

THE latest number of the *Zeitschrift für wissenschaftliche Zoologie* (vol. lxix. part 2) contains three articles dealing with invertebrates. The first, by Herr J. Grofs, treats of the ovary of hemipterous insects; in the second, Herr C. Dawydoff treats of the process of regeneration among the brittle stars; while in the third, Herr O. Bütschli gives the results of his investigations into the nature of siliceous and calcareous sponge-spicules. In the latter it is shown that sponge-spicules, under the influence of heat, display minute cavities, which it is inferred exist under normal conditions, although too small to be detected. The

composition of both the organic and inorganic constituents of the calcareous spicules is worked out, the mineral matter being a double salt of $CaCO_3$ and K_2CO_3.

SERIOUS students of the science of meteorology will welcome Dr. J. Hann's "Lehrbuch der Meteorologie," the publication of which has just been commenced by the firm of Tauchnitz, Leipzig. The work will be completed in eight parts, and it is to be hoped that they will follow one another in quick succession. The first part contains a general introduction on the physics and chemistry of the atmosphere, and sections on radiation and daily and annual ranges of temperature. There are also charts showing the isotherms of the world in January, July, and of the year, and also representing the paths of hurricanes in the North Atlantic Ocean. The work will be reviewed when all the parts have been received.

WE have already referred on two or three occasions to the dispute between the authorities of Kew Observatory and the West London Tramways. The subject of the dispute—whether the currents leaking from the tramway rails would affect the readings of the magnetometers at Kew—was put to the test of experiment on Friday last, when the Board of Trade inspection of the electrical equipment of the Tramways was carried out by Mr. Trotter. For an hour or two the ordinary horse-car trams were replaced by electrically-driven cars, thirty of which were run on the line between Hammersmith and Kew. During this trial observations were made on the measuring instruments in the generating station by Mr. R. T. Glazebrook on behalf of Kew Observatory. It will be possible, by comparing the records thus obtained with the readings of the instruments at Kew during the time of the trial, to determine how far the leakage currents are likely to interfere with the value of the Kew records. Should an appreciable effect be observed, an arrangement will have to be made between Kew and the Tramways as to the amount of compensation to be paid by the latter for the cost of removing the instruments.

THE prospects of agricultural developments in South Africa were described by Prof. R. Wallace at a meeting of the Colonial Institute on March 12. After referring in detail to the crops produced in Cape Colony, the scanty herbage, the rearing of sheep and goats, the production of wool, ostrich-farming, the breeding of cattle, forest areas, and the products of Natal, he alluded to the Transvaal and the Orange River Colony. The south-eastern parts of the Transvaal, including New Scotland, he said, were specially suitable for sheep-breeding as well as for agriculture, the high central area for cattle and corn, the northern and lower elevations for coffee and sugar plantations and for tropical fruit culture. Good tobacco was largely grown in the Transvaal for export to other districts of South Africa. A great deal had been written about irrigation being the probable salvation of the country. Many small local ventures had been marvellously successful in transforming what was desert into gardens of Eden, and a good many promising irrigation schemes had been examined in various districts of Cape Colony, but most of them involved the expenditure of a large amount of capital and would require to be worked with much skill and care to make them pay. Without irrigation, the extent of South Africa that was capable of cultivation with satisfactory results was an infinitesimal fraction of the whole, and even that was subjected to periodical droughts which at times destroyed a whole season's crop; to destructive hailstorms, which were specially prevalent on the central plateau; and to fungoid parasitic pests on the common grain crops, which made the growth of European cereals practically impossible during the wet season of summer. It was highly probable that among the new disease-resisting breeds of cross-fertilised grains which had been produced at Newton-le-Willows by the brothers Garton, species of both oats and wheat might be found on experiment to overcome this difficulty; but still sufficient reasons remained why South Africa would never be a great agricultural country capable of exporting grain. With the development of the local irrigation schemes that were possible and better systems of management, it might more nearly produce the amount of food requisite for internal consumption.

THE *Newcastle Daily Journal* announces the death of Mr. Richard Howse, one of the old school of naturalists, who had been for half a century actively identified with the Natural History Society in Newcastle, and since the new museum was opened at Barras Bridge sixteen years ago he discharged the duties of curator. For a considerable period he acted as one of the secretaries to the Tyneside Naturalists' Field Club, and was also editor of its transactions. Mr. Howse was one of the first geologists to study the Permian rocks of the north-east coast, and he made a number of important observations of the carboniferous fossils of the north of England, many interesting specimens of which have been named after him. He was a prolific writer, and in addition to many papers which were published in the transactions of the local societies, he prepared an interesting "Guide to the Natural History Museum." He compiled other volumes dealing with the exhibits in the Barras Bridge Museum, amongst the number being a "Guide to the Collections of Local Fossils," and a "Catalogue of the Fishes of the Rivers and Coast of Northumberland and Durham." Prior to this publication, no systematic list of the fishes found on the coast and in the rivers of Northumberland and Durham had been issued. Mr. Howse also published an index catalogue of birds in the Hancock collection and a catalogue of Permian fossils, and was joint editor with Mr. J. W. Kirby of a "Synopsis of Geology of Northumberland and Durham."

A METHOD of distinguishing human blood from that of animals has been discovered independently by Dr. Uhlen-Luth, of Greifswald, and Drs. Wassermann and Schutze, of Berlin, and is described in the *Medical Press and Circular* of March 13. From this account of the investigations it appears that it is now possible to obtain a definite reaction from blood-stains, however old, which indicates with something approximating absolute certainty the source of the blood under examination. This result is based on the fact that the blood serum of animals which have been injected with the blood of an animal of a different species, when added to a dilution of blood from the latter, produces therein a well-marked precipitate. Thus, if a rabbit be injected with human blood, the serum of the rabbit blood, when added to a dilution of human blood, causes immediate turbidity, a phenomenon which is conspicuous by its absence when it is added to dilutions of any other kind of blood. The only element of uncertainty is that the blood of monkeys reacts, to some extent, in the same way as human blood; but apart from the fact that the medico legist is seldom likely to be called upon to differentiate between these two varieties, there is a notable difference in the length of time required for a dilution of monkey's blood to become cloudy as compared with that of man. Full details of the procedure will be found in our contemporary.

THE Meteorological Council have just published a series of charts illustrating the weather of the North Atlantic Ocean in the winter 1898–9. This period was marked by a succession of severe gales, and it will be remembered that public interest was especially aroused by the anxiety as the safety of the liners *Pavonia* and *Bulgaria*. The charts illustrate the state of the weather from December 18, 1898, to February 15, 1899, com piled from observations from the log-books of some 200 vessels,

and show that during the month of January and the first half of February the weather was exceedingly boisterous, and the period was also noteworthy by the great difference of temperature between the eastern and western shores of the Atlantic. For instance, between Fort Logan, in Montana (latitude 47° N.), with its terribly severe frost of − 61° in the night of February 10, and Liège in Belgium (latitude 48° N.), with its temperature of 70°·5 on the afternoon of the 10th, there was a difference of 131°·5, while over extensive regions of America and western Europe there was a difference of more than 100°. This combination of circumstances seemed to indicate the occurrence of some peculiar atmospheric conditions of which the Meteorological Council considered a permanent record was desirable.

THE *Proceedings* of the American Academy of Arts and Sciences for January contain a description of an ingenious apparatus devised by Mr. F. A. Laws for recording alternating current waves. The system is a modification of the "point-to-point" or "contact" method; by a mechanical arrangement which automatically shifts the position of the contact brushes, the galvanometer deflection instead of being changed intermittently is made to alter gradually, thus slowly following the wave-form. The reflected spot of light is received on a moving photographic plate on which it imprints a record of the wave-form. The method only gives the average wave-form, but inasmuch as this is obtained in a few minutes, it is a considerable improvement on the older "point-to-point" systems. But now that oscillographs have been developed into thoroughly practical instruments by Blondel, Duddell and others, the "point-to-point" method must be regarded, we think, as having had its day.

SOME experiments on the heat evolved when powders are wetted are described by Signor Manfredo Bellati in a recent pamphlet (printed by Carlo Ferrari, of Venice, 1900). It has been suggested as an explanation of the phenomena that the heating is due to the compression produced in the stratum of liquid immediately surrounding the solid, and this explanation has been confirmed by the experiments of Jungk, according to which, when the water is below 4° C., cooling, instead of heating, takes place, such as would occur in water below the temperature of maximum density when subjected to an increase of pressure. This result has been negatived by the experiments of Meissner. The present writer points out, however, that since the effect of pressure is to lower the point of maximum density, it does not necessarily follow that cooling must always occur at temperatures below 4° C., and hence the above hypothesis is not necessarily inconsistent with Meissner's results. In Signor Bellati's experiments dry sand was found to become heated when wetted with water even at a temperature of 0° C. When the sand had been previously moistened, however, the author found that at 0° C. heating occurred when the sand contained more than 2·1 or less than 1·4 per cent. of water, but that with percentages between these limits cooling sometimes took place instead. The author describes some further experiments conducted with the object of testing Canton's and Martini's theory.

IN addition to other communications, the second part of the Bergens Museum *Aarbog* contains two papers, one by Mr. O. Nordgaard and the second by Mr. E. Jorgensen, dealing with the "plankton" of the North Sea, as well as one by Emily Arnesen, treating of the sponges of the Norwegian coasts. In the *fjords* of western Norway it is ascertained that the deep plankton fauna is of an Arctic character; copepods existing in the deep layers, where Atlantic conditions prevail, which attain their maximum development, both as regards size and number, in the Arctic Ocean. We have likewise received the *Aarsberetning* of the Bergen Museum, in which we notice an excellent reproduction of a photograph of a portion of the zoological gallery.

THE first fasciculus of an important work on the Hydroids, or Hydromedusæ, of the North American seas, now in course of publication by the Smithsonian Institution as *Special Bulletin* No. 4, has been received. The rich material for the history of this group of zoophytes accumulated in the U.S. National Museum, as one of the results obtained by numerous dredging expeditions of late years, has never hitherto been worked out, and the detailed investigation now being undertaken promises very important additions to our knowledge of the group. The present fasciculus, by Prof. C. C. Nutting, of Iowa University, deals with the Plumulariidæ, of which it is doubtful if more than fifty North American species were previously known. The result of the investigation is to show that, in place of Australia, the West Indian area is the richest in plumularian life of any region of the equal size in the world.

WE have received the *Sitzungsberichte* of the Royal Bohemian Society for 1900, which forms a thick volume containing, among other matter, nine articles on zoological and the same number on botanical subjects. Of the former perhaps the most interesting is one by Dr. A. Mrázek, describing the discovery of a small freshwater nemertine worm in a tank in one of the hothouses in the Botanical Garden at Prague. So little is at present known of the freshwater representatives of this group that every new fact is of importance; but since specimens have been found in regions so far apart as Nicaragua and Turkestan, there can be little doubt that some forms are indigenous to freshwater. The specimen described by Dr. Mrázek is identical with *Stichostoma* or *Tetrastemma*, *graecense*, of which the other known example was taken in a warm-water tank in the Botanical Garden at Gratz; the species is, therefore, probably introduced. The author adds some general remarks with regard to freshwater faunas.

THE issue of the *Revue Scientifique* (*Revue Rose*) of March 9 contains a long and interesting article by M. Louis-Adrien Levat on the destruction of birds, especially by means of traps and snares, which he declares to be illicit. After a brief survey of the persecution to which birds were exposed in ancient times, and reference to the fact that taking the hen sitting on her nest is expressly forbidden by the Mosaic code, the author goes on to say that during a single spring a few years ago no less than 1500 nests were taken in one French province. This represents a prospective loss of about 6000 birds, which might be expected to consume some 6,000,000 insects among them. He adds the significant observation that in the year 1860 one hundred cages filled with insectivorous birds of various kinds were exported from Baden to New South Wales; and that at the present day it would be almost impossible to send such another cargo, owing to the scarcity of these birds on the continent. And it is not alone the disappearance of bird-life and bird-song from the country districts that is to be deplored. The effects on agriculture, horticulture and the grape industry are simply disastrous. Some birds, it is computed, will consume 200,000 insects per season, and others as many as 600 per day. A single insect-eating species may be the means of saving 3200 grains of wheat and 1150 grapes daily! In Hérault alone the destruction of insectivorous birds is calculated to cost the department 100,000 hectolitres of wine annually. And in some districts of France the country is practically desolated by insect ravages owing to bird-slaughter. From the fact that in France so-called sportsmen are in the habit of shooting small birds, the situation is much worse than in England. Remedial measures are urgently needed, but the author says he is preaching to deaf ears.

THE Trinidad *Bulletin of Miscellaneous Information* states that a recent analysis made by Prof. Carmody, Government Analyst, confirms the previous work of Francis as to the presence of prussic acid in sweet cassava, the proportion found

varying from 0·005 to 0·019 per cent. The skin was found to yield from 0·014 to 0·042 per cent., while the inner part gave only 0·003 to 0·015 per cent. The interior part of bitter cassava yielded 0·013 to 0·037 per cent., while the skin and outer layer yielded from 0·012 to 0·035 per cent. Peeling sweet cassava before cooking is therefore a wise precaution. Prof. Carmody also suggests that the acid may in part be formed by fermentative change.

MR. C. THOM (*Trans.* Acad. Sci. St. Louis, ix. No. 8) gives an account of the details of fertilisation as observed in ferns belonging to the genera Aspidium and Adiantum. In describing the development of the spermatozoa he states that a blepharoplast is present in the cytoplasmic part, and that the nuclear portion really consists of a hollow tube, chiefly composed of chromatin, enclosing a core of a substance probably representing a transformation of nucleolar matter. When the sperm reaches the archegonium, the cytoplasmic envelope becomes more or less functionless, and the nuclear part wriggles to the egg by an autonomous movement. The cytoplasmic portion containing the blepharoplast either is thrown off before the egg is entered or it is detached and disintegrates in the egg cytoplasm. Hence the importance which has been ascribed to this body, as the result of a comparison with animal centrosomes would seem to have been exaggerated. The coiled nuclear part of the sperm enters the nucleus of the egg, in which it can be recognised for some time. Ultimately, however, the mixing of the egg and sperm nuclear constituents becomes so complete that finally no difference between the sexual elements can be detected.

THE report of the work of the Division of Forestry of the U.S. Department of Agriculture during the year 1900 has been issued. The year witnessed a conspicuously wider and more effective and intelligent interest in forest matters in the United States than any previous year. To give an idea of the extent of the work it may be mentioned that during the year applications were received for working plans for 48,078,449 acres, personal examinations on the ground were made of 2,103,670 acres, working plans were begun upon 1,325,000 acres; plans were completed for 179,000 acres, and 54,000 acres were put under management. In accordance with the request of the Secretary of the Interior, the preparation of a working plan for the Black Hills Forest Reserve was begun as the first step toward conservative lumbering on the national forest reserves. A unique and most promising study of the effect of forest cover on the flow of streams has been commenced in southern California upon the lands of the Arrowhead Reservoir Company, whose observations of precipitation, run-off, evaporation and temperature for eight years have been placed at the disposal of the Division of Forestry. A careful study of the subordinate watersheds, which differ completely among themselves in the character of their forest covering, has been undertaken, and strong hopes are entertained of valuable results from the comparison of the run-off from various types of cover. An investigation of the value of the widespread views regarding the effect of denudation upon the once forested lands bordering the Mediterranean Sea has been begun, and the conditions in Tunis, Algeria and Tripoli have been studied.

WE have received a reprint from the Twelfth Annual Report of the Missouri Botanic Garden, a monograph of the Crotons of the United States, by Mr. A. M. Ferguson. It includes about twenty-four species, and is illustrated by thirty-one plates.

A DAINTY and cheap edition—the price is only eighteenpence net—of Izaak Walton's "Complete Angler," has been published by Messrs. Gay and Bird. This matchless idyl of angling and its associations, first appeared in 1653, and the present volume is a reprint of the text of the fifth edition (1676), as revised by Sir John Hawkins. The book is just the kind of volume to slip into the coat pocket, to be read at quiet moments by contemplative naturalists, whether anglers or ramblers, who find pleasure in observing nature.

SEVERAL interesting articles upon scientific subjects appear in the March magazines which have come under our notice. The *Idler* contains an instructive description of the Jena glass works and of Prof. Abbe's researches. Mr. Walter Wellman describes some experiences of his Polar expedition of 1898–1899. A fine series of instantaneous photographs showing the forms assumed by water thrown out of a bucket is reproduced in *Pearson's Magazine*. Dr. Louis Robinson describes popularly how adaptation to environment may lead to the survival of such animals as the giraffe, camel and zebra; and a description is given of a trip in an immersible boat, the *Argonaut*. In *Scribner's Magazine* some of the geographical discoveries made between 1825 and 1900 are shown by comparative maps. *Good Words* contains articles on Mr. Edison, insect pests, and the building of the locomotive.

THE current number of the *Berichte* contains a paper by W. Ipatieff upon the action of a high temperature upon alcohols. Since the researches of Berthelot upon the substances produced when various substances are passed through red-hot tubes, very little work has been done in this direction. It is now found that in the case of alcohols the reaction is a much simpler one than would be expected, the corresponding aldehyde being the chief product. In many cases the yields are so good that it forms an advantageous method for the preparation of certain aldehydes. The hot tube may be of glass or iron, preferably the latter, the temperature giving the best yields being about 700°. Methyl alcohol treated in this way gave 25 per cent. of the theoretical quantity of formaldehyde, isobutyl alcohol about 40 per cent. and isoamyl alcohol 30 to 40 per cent. of the corresponding aldehydes.

OWING to the fact that the values obtained for the atomic weights of iodine and tellurium are inconsistent with their relative positions in Mendeléeff's table, numerous determinations of the atomic weight of the latter element have been made in recent years, the results obtained varying between 127·5 (Staudenmayer) and 128 (Wills), all being above that of iodine (126·8) instead of below it as required by the periodic law. As is pointed out, however, by Herr O. Steiner in the current number of the *Berichte*, all these determinations of the atomic weight of tellurium are based upon the analysis of inorganic preparations, the methods of purification adopted giving no complete guarantee that small quantities of substances of similar properties but different atomic weights may not be present. The fact that tellurium forms a stable and well-defined diphenyltelluride, $Te(C_6H_5)_2$, distilling without decomposition in a vacuum, was therefore utilised for a fresh determination. Although these preliminary results have not the high degree of precision necessary for the complete resolution of the problem, Herr Steiner points out that the accuracy obtainable by an ordinary combustion is sufficient to fix the atomic weight of tellurium to within 0·5, and several results obtained by combustion of the carefully fractionated product gave a mean value of 126·4, a figure much lower than those mentioned above and agreeing with the prediction of the periodic table. As a confirmation of the method, a similar set of experiments upon diphenylselenide gave the values 78·8 and 79·3, the number usually adopted being 79·1. The results of more exact determinations carried out upon material purified by this method will be awaited with interest.

THE additions to the Zoological Society's Gardens during the past week include a Dingo (*Canis dingo*) from Australia,

presented by Mr. W. R. Temple; a Pinche Monkey (*Midas aedipus*) from Colombia, presented by Lady Moor; a West African Python (*Python sebae-natalensis*) from Natal, presented by Mr. Alex. Buchanan; a Spotted Ichneumon (*Herpestes auropunctatus*), four Hamilton's Terrapins (*Damonia hamiltoni*), seven Bungoma River Turtles (*Emyda granosa*), eight Roofed Terrapins (*Kachuga tectum*) from India, a Common Boa (*Boa constrictor*) from South America, deposited; a Maguari Stork (*Dissura maguari*) from South America, four Gouldian Grass Finches (*Poëphila gouldiae*) from Australia, purchased.

OUR ASTRONOMICAL COLUMN.

Nova Persei.— Prof. H. C. Vogel describes, in the *Astronomische Nachrichten* (Bd. 154, No. 3693), the results of measures of photographs of the spectrum of Nova Persei, taken with the 80 cm. refractor and spectrograph of small dispersion. The spectra extend from λ 3740 to λ 5800. Wave-lengths have been determined by comparisons with the spectrum of β Orionis (Rigel). Tables of the wave-lengths of the deduced lines are given, the origins being traced to hydrogen, calcium, magnesium and silicon. The displacements of the lines is shown to indicate a velocity of some 700 kilometres per second relative to the earth; an exception to this occurs in the case of the two calcium lines at H and K, which are indicated as giving velocities of approach of only 45 kilometres per second.

Variability of Eros.—At the Lyons Observatory MM. Guillaume, Le Cadet and Luizet have recently obtained a series of estimations of the variations in the brightness of Eros, observing with an equatorial coudé of 0·32 metre aperture and a Brunner equatorial, 0·16 metre aperture. A diagram of the light curve is given. This is similar to that of β Lyræ, but the secondary minimum is almost equal to the principal one. The determinations gave

		h. m.
Principal minimum to secondary minimum	=	2 51
Secondary ,, principal ,,	=	2 24
Principal maximum to secondary maximum	=	2 50

Details of estimates on seven nights during February are given (*Comptes rendus*, cxxxii. pp. 530-531).

In the same issue M. Luizet gives the elements for computing future minima as follows:—

$$1901 \text{ Feb. } 20. \ldots \left.\begin{matrix} 7^{h}\,57^{m} \\ 10\;48 \end{matrix}\right\} + 5^{h}\,16^{m}{\cdot}15\ \text{E.}$$
$$\phantom{1901 \text{ Feb. }} 20. \ldots$$

The eccentricity of the orbit of the system would thus be about 0·0569, which is nearly equal to that of the moon's orbit (0·0549).

In the current issue of the *Comptes rendus*, M. L. Montangerand describes the photographic investigations which have been made with the astrographic refractor at the Toulouse Observatory. It is interesting to note that the measures so obtained agree very well with visual determinations. The planet was allowed to trail over the plate, and the points of equal brightness marked off at intervals. The period thus found is given as 2h. 38m. (2h. ·63) (*Comptes rendus*, cxxxii. pp. 616–618).

In close agreement with this result is the determination of Prof. Deichmüller at Bonn, who gives 2h. ·61 as the period of variation. This observer gives also, for the two evenings of February 21 and 22, a series of estimations of magnitude at intervals of ten minutes from 5·0 to 10·0 p.m. (*Astronomische Nachrichten*, Bd. 154, No. 3693).

New Variable, 2 1901 (Cygni).—Dr. T. D. Anderson announces, in the *Astronomische Nachrichten* (Bd. 154, No. 3692), the discovery of a new variable star. Its position is

$$\left.\begin{matrix} \text{R.A.} = & 19^{h}\; 12^{m}{\cdot}2 \\ \text{Decl.} = & +\,49^{\circ}\; 55' \end{matrix}\right\}(1855{\cdot}0).$$

And the variations recorded are

1900	Dec. 26	...	9·5
1901	Jan. 12	...	9·8
	Feb. 16	...	10·4

Observations of Circumpolar Variable Stars.—Vol. xxxvii. part 1 of the *Annals* of the Harvard College Observatory contains the results and discussion of the observations of 17 circumpolar variables made at the institution during the period 1889–1899. The estimates of magnitude were made by Argelander's method, but differ from similar observations of other workers in two respects—first, the stars have been observed throughout the whole period of their variation of light; and second, all the observations have been reduced to a uniform photometric scale, that of the meridian photometer. This latter peculiarity is of great importance, as by its means the stars can not only be systematically compared *inter se*, but collateral comparisons made with stars of constant brightness in any part of the sky. Both the 15 inch and 6-inch equatorials have been employed in the work.

Three of the stars, T Persei, S Persei and R Ursæ Minoris appear to be irregularly variable. With the exception of these, mean light curves have been deduced for the variables, and tables are given showing the phases obtained by this means. An examination of the curves shows that the principal maximum is in several cases preceded, and in a few cases followed, by a more or less marked *secondary* maximum.

Treating these variables as a class, it is noted that the

mean of all the periods ...	=	363·4 days
mean magnitude at maximum	=	7·81
,, ,, ,, minimum	=	12·64
So that the range is therefore	=	4·83 magnitudes.

Drawings are given of the mean light curves of 14 of the variables, and 16 small charts showing their positions with respect to the surrounding stars.

EROS AND THE SOLAR PARALLAX.

Few projects involving long continued observation and laborious calculations have received a more ready assent or commanded a wider co-operation than that which has for its aim the determination of the solar parallax from observations of the planet Eros. This readiness to adopt a general programme was materially assisted by the meeting of the International Astrophotographic Congress at Paris, in July 1900, whereby the directors of many of the best equipped observatories were able to rapidly mature their plans and to complete the necessary organisation. The representatives of some twenty observatories gave in their adhesion to the proposal, which contemplates the collection of measures, either photographic, micrometrical or heliometric, and the necessary meridian observation of a large number of comparison stars. The general scheme follows the well-known lines of utilising observations made at considerable hour angles east and west of the meridian at any one observatory, of combining the observations made in the north and south hemispheres, and adds the somewhat novel feature of making available simultaneous observations of the planet at stations in America and Europe, a suggestion which, among other advantages, has the effect of eliminating errors arising from an imperfect knowledge of the planet's motion.

Under date, Paris, January 31, M. Loewy gives an interim report of the progress of the observations up to the end of the year 1900. M. Loewy and those responsible for the inception of the scheme are to be congratulated on the energy exhibited and the hopeful results obtained. The report states that, notwithstanding the bad weather that has generally prevailed in the northern regions of our hemisphere, not one day has passed in which the planet has not been observed by one or other of the several methods adopted. The number of coincidences of observation between the three contributing American observatories and those in Europe is shown by the following figures:—

Number of Coincidences up to December 31, 1900.

	Madison.	Washington.	Williams Bay (Yerkes).	Total.
Micrometric ...	40 ...	49 ...	106 ...	195
Photographic ...	15 ...	30 ...	66 ...	111

The English observatories of Oxford and Cambridge (Greenwich is not reported) are in the least favourable position, since the arc of the Great Circle intercepted between them and the average American station is only about 55°; but seeing that the parallax of the sun can be determined quite independently of the motion of the planet, and that the stars of comparison will be the same in the two cases, a very small error can be anticipated under the least favourable conditions. Considerable attention has been given to the amount of this error, and one

can only hope that the favourable presage will be realised. The probable limit of error is based upon a preliminary inquiry due to M. Hermann Struve, of Königsberg, who has found that the probable error of a single complete micrometrical measurement is $\pm 0''.077$, and such an error would introduce no greater uncertainty into the parallax than $0''.03$, a most satisfactory result for one night's determination. Such a favourable result, however, implies (1) that we are in possession of the accurate diurnal motion of the planet; (2) that no error exists in the relative position of the stars of comparison, and (3) that every source of systematic error has been eliminated. It is not unimportant to observe in this connection that the motion of the planet itself in one second of time can amount to, and even exceed, $0''.03$ in the arc of a great circle, no inconsiderable fraction of the total error found by M. Struve. The actual epoch of exposure, with a rapidly moving shutter, would probably be known to much less than a second of time, but the proper moment to assign to the formation of the image seems to be open to more doubt. A question of very similar import has been discussed at Paris by M. Henry, and has been reported upon. This has reference to the formation of the trace of the planet on the sensitised film, when the equatorial is driven to sidereal time by means of a star. M. Henry photographed a region of the sky with an exposure of three minutes, in which an acceleration and retardation of three seconds was alternately given to the driving clock. Two other exposures were made on the same plate in the reversed order, and the differences of right ascension of the centres of the traces were measured. The mean of the differences of the measured distance with clock accelerating was compared with the mean of the distances clock retarding, in groups according to magnitude, with the following result:—

Number of stars.	Mean magnitude.	Mean diff. of distance.	Prob. error of the mean.	Prob. error of a distance.
		$''$	$''$	$''$
13	9·3	+0·10	±0·02	±0·06
20	11·3	−0·03	±0·02	±0·09
25	12+	−0·02	±0·03	±0·13

The large probable error in the third group is quite sufficiently explained by the faintness of the stars and the shortness of the exposure, but we seem to be in presence of errors of quite the same order of magnitude as those found by M. Struve. Certainly one of the most interesting of the results that will proceed from this elaborate programme will be the relative certainty and freedom from systematic errors of the various methods of observing.

This memoir or report also contains, besides an ephemeris of the planet supplied by M. Millosevich and a table of star constants applicable to the stars used in the discussion of the photographic plates, a memoir by Mr. Comstock on the computation of refraction in the direction of the diurnal motion of the planet. Other points which have been discussed are crowded out of the present number, but enough is given to assure us that the International Committee forms a centre of activity calculated to attract the energy and the enterprise of all the cooperating astronomers. But it is impossible to anticipate, as the result of so much labour, anything more than an academic interest. Based upon the constants employed in the reduction and an assumed figure of the earth, the resulting parallax will represent the best value procurable from an isolated inquiry; but in view of the solemn acceptance of the value $8''.80$ for the solar parallax at the Paris Congress in 1896, it seems extremely improbable that the various national ephemerides will make any alteration in a value which has been so recently introduced.

FORTHCOMING BOOKS OF SCIENCE.

Mr. Edward Arnold announces:—"The Physiological Action of Drugs, an Introduction to Practical Pharmacology," by Dr. M. S. Pembrey and Dr. C. D. F. Phillips; "The Morphology of the Brain: an Introduction to the Study of the Comparative Anatomy of the Brain in the Vertebrata," by G. Elliott Smith; "A Text-book of Biology," by G. P. Mudge; "Applied Embryology and Morphology," by Dr. A. Keith; "Anthropology and its Practical Value," by E. W. Brabrook; "A School Botany: being an Introductory Text-book on the Study of Flowering Plants," by David Houston, illustrated; "Wood: a Manual of the Natural History and Industrial Applications of the Timbers of Commerce," by Prof. G. S. Boulger; "A Handbook on Fermentation and the Fermentation Industries," by Charles G. Matthews; "The Dressing of Minerals," by Prof. Henry Louis; "Traverse Tables for Surveyors and Engineers," by Prof. Henry Louis and G. W. Caunt; "Physical Calculus," by Rev. P. E. Bateman.

The announcements of Messrs. Baillière, Tindall and Cox include:—"Cerebral Science: Studies in Comparative Psychology," by Dr. Wallace Wood, illustrated; "Gold and Diamonds: South African Facts and Inferences," with coloured maps and thirteen plates, by W. H. Penning; "Suggested Standards of Purity for Foods and Drugs," by C. G. Moor, Cecil H. Cribb, and Martin Priest.

Mr. B. T. Batsford promises:—"Sanitary Engineering," by Colonel E. C. S. Moore, illustrated; and a new edition of "New Tables for the Complete Solution of Ganguillet and Kutter's Formula," by Colonel E. C. S. Moore.

Messrs. A. and C. Black will publish:—"Encyclopædia Biblica," edited by Rev. Prof. Cheyne and Dr. J. Sutherland Black, vol. iii.; "Geography of South America," by L. W. Lyde; "World Pictures and Problems, an Elementary Pictorial Geography," by Joan B. Reynolds, illustrated; "New Descriptive Geography of Africa," edited by Dr. A. J. Herbertson and F. D. Herbertson; "Introduction to the Study of Physics," by A. F. Walden and J. J. Manley, vol. i., General Physical Measurements, illustrated; "A Treatise on Elementary Statics," by W. J. Dobbs.

The announcements of the Cambridge University Press include:—"Scientific Papers," by John William Strutt, Baron Rayleigh, F.R.S., vol. iii.; "Papers on Mechanical and Physical Subjects," by Prof. Osborne Reynolds, F.R.S., reprinted from various transactions and journals, vol. ii.; "Scientific Papers," by the late Dr. John Hopkinson, F.R.S., in 2 vols.; "A Treatise on Determinants," by R. F. Scott, a new edition by G. B. Mathews, F.R.S.; "A Treatise on Spherical Astronomy," by Prof. Sir Robert S. Ball, F.R.S.; "Zoological Results based on Material from New Britain, New Guinea, Loyalty Islands and Elsewhere, Collected during the Years 1895, 1896 and 1897," by Dr. Arthur Willey. Part v. An account of the Entozoa, by A. E. Shipley, with 3 plates; of the Nemertina, by R. C. Punnett, with 5 plates; the development of the Robber Crab (*Birgus*), by L. A. Borradaile, with 8 figures in the text; new genera and species of Entomostraca, by the Rev. T. R. R. Stebbing, F.R.S., with 5 or 6 plates; anatomy of *Neohelia porcellana* (Moseley), by Edith M. Pratt, with 2 plates. The entire work will be completed with the publication of part vi., which will be issued during 1901, and will contain Dr. Willey's monograph on *Nautilus* and other articles, including an account of the Ascidians, by Prof. W. A. Herdman, F.R.S.; "Reports of the Anthropological Expedition to Torres Straits by the Members of the Expedition," edited by Prof. A. C. Haddon, F.R.S., vol. ii., Physiology and Psychology; "Fauna Hawaiiensis, or the Zoology of the Sandwich Islands," being results of the explorations instituted by the Joint Committee appointed by the Royal Society of London for Promoting Natural Knowledge and the British Association for the Advancement of Science, and carried on with the assistance of those bodies and of the trustees of the Bernice Pauahi Bishop Museum, edited by Dr. David Sharp, F.R.S., Secretary of the Committee; "Zoology," by Prof. E. W. MacBride and A. E. Shipley; "Lectures on Great Physiologists," by Prof. Sir Michael Foster, Sec. R.S.; "Fossil Plants, a Manual for Students of Botany and Geology," by A. C. Seward, F.R.S., vol. ii.; "The Soluble Ferments and Fermentation," by Prof. J. Reynolds Green, F.R.S., new edition; "British Grasses," by Prof. H. Marshall Ward, F.R.S.; "Electricity and Magnetism," by R. T. Glazebrook, F.R.S.; "The Teacher's Manual of School Hygiene," by Dr. E. W. Hope and Edgar Browne; "An Introduction to Logic," by W. E. Johnson; "Euclid, Books I.-III., with Simple Exercises," by R. T. Wright; "An Introduction to Physiography," by W. N. Shaw, F.R.S.; "A Brief History of Geographical Discovery since 1400," by Dr. F. H. H. Guillemard; "A New Primer of Mechanics," by Prof. L. R. Wilberforce; "A New Primer of Physics," by the same author.

Messrs. Cassell and Co., Ltd., give notice of:—A cheap monthly re-issue of the Century Science Series, edited by Sir Henry Roscoe, F.R.S.; "The Herschels and Modern Astronomy," by Agnes M. Clerke; "Pasteur," by Prof. Percy Frankland, F.R.S., and Mrs. Percy Frankland; "James Clerk Maxwell and Modern Physics," by R. T. Glazebrook, F.R.S.;

"Humphry Davy, Poet and Philosopher," by Dr. T. E. Thorpe, F.R.S.; "Major Rennell, F.R.S., and the Rise of Modern English Geography," by Sir Clements R. Markham, F.R.S.; "Justus Von Liebig: His Life and Work," by W. A. Shenstone, F.R.S.; "Charles Lyell and Modern Geology," by Prof. T. G. Bonney, F.R.S.; "John Dalton and the Rise of Modern Chemistry," by Sir Henry E. Roscoe, F.R.S.; "A Practical Method of Teaching Geography" (England and Wales, part ii.), by J. H. Overton; "Pictorial Practical Fruit Growing," a concise manual giving instructions for the management of every important fruit in cultivation, by W. P. Wright, illustrated; and re-issues of "Familiar Wild Birds," by W. Swaysland, illustrated, and "Cassell's Natural History," illustrated.

Messrs. J. and A. Churchill's list includes:—"A Treatise on Physics," by Prof. A. Gray, F.R.S., in three parts, illustrated, part i., Dynamics and Properties of Matter; "Gynæcological Pathology," by Dr. Charles Hubert Roberts, illustrated; "Diseases of the Thyroid Gland, and their Surgical Treatment," by Dr. James Berry, illustrated; "Handbook of Clinical Medicine for Practitioners and Students," giving an account of the diagnosis, prognosis and treatment of disease, by Dr. Thomas D. Savill, illustrated; and a new edition of "Carpenter's Microscope and its Revelations," edited by Rev. Dr. W. H. Dallinger, F.R.S., illustrated.

In the announcements of the Clarendon Press we observe:—"Micro-Anatomy," by G. Mann; "A Text-Book of Arithmetic," by R. Hargreaves; "Geometrical Exercises," by Prof. A. Larmor; "The Works of George Berkeley," edited by A. C. Fraser, 4 vols.; "The Ethics of Spinoza," by H. H. Joachim.

Messrs. Dent and Co. announce:—"Bird Watching," by E. Selous, illustrated.

Mr. Gustav Fischer (Jena) announces:—"Studien über die Narkose," by Dr. Overton; "Weiteres über Malaria. Immunität und Latenzperiode," by Dr. A. Plehn, illustrated; "Die Parasiten im Krebs und Sarkom," by Dr. Max Schüller, illustrated; "Das Gesetz der Güterconcentration in der individualistischen Rechts- und Wirtschaftsordnung," Erster Halbband: Das Gesetz der Güterconcentration und seine Bedeutung für die Wirtschaftspolitik, by Dr. J. Worms; and a new edition of "Die moderne Weltanschauung und der Mensch," by Dr. B. Vetter.

The announcements of Messrs. C. Griffin and Co., Ltd., include:—"The Construction and Maintenance of Vessels Built of Steel," by Thomas Walton, illustrated; "The Metallurgy of Steel," by F. W. Harbord, illustrated; "Hints on Steam Engine Design and Construction," by Charles Hurst, illustrated; "A Text-Book of Physics," by Profs. J. H. Poynting, F.R.S., and J. J. Thomson, F.R.S.:—"Properties of Matter," illustrated; "Tables and Data for the Use of Analysts, Chemical Manufacturers, and Scientific Chemists," by Prof. J. Castell Evans; "A Dictionary of Dyestuffs: A Compendium of Dyes, Mordants, and other substances employed in Dyeing, Calico-Printing, and Bleaching," by C. Rawson, W. M. Gardner, and Dr. W. F. Laycock; "A Dictionary of Textile Fibres," by William J. Hannan, illustrated; "Sanitary Engineering: A Practical Manual of Town Drainage and Sewage and Refuse Disposal," by Francis Wood, illustrated.

Messrs. J. Hall and Co. give notice of:—"Army Science Papers, being papers in chemistry, physics, physiography and geology, set in the Woolwich, Sandhurst and Militia Literary Examinations, 1890-1896"; "Army Mathematical Papers, being papers in arithmetic, algebra, Euclid, trigonometry and mensuration, set in the Sandhurst and Militia Literary Examinations (Class I.), 1890-1896," with answers by T. A. E. Sanderson.

Mr. W. Heinemann announces:—"A Universal History of Mankind," edited by Dr. Helmolt, vol. i. Introductory Pre-history—America and the Pacific Ocean; "Britain and the North Atlantic," by H. J. Mackinder.

Messrs. Hy. Holt and Co. (New York) will publish "The Anatomy of the Cat," by Profs. Reighard and Jenning, illustrated.

Messrs. Isbister and Co., Ltd., will issue:—"Nature and the Child," by C. B. Scott, illustrated; "Differential and Integral Calculus," with applications, by Prof. E. W. Nichols; "Experimental Chemistry," by Dr. Lyman C. Newell, Teacher's Supplement; Heath's Mathematical Monographs, issued under the general editorship of Prof. Webster Wells: (1-4) "Famous Geometrical Theorems and Problems and their History," by W. W. Rupert; (5) "On Teaching Geometry," by Florence Milner.

Messrs. Jarrold and Sons announce:—"Letters and Notes on the Natural History of Norfolk, more especially on the Birds and Fishes," from the MSS. of Sir Thomas Browne, M.D. (1605-1682), in the Sloane Collection in the Library of the British Museum, with notes by Thomas Southwell.

Messrs. Crosby Lockwood and Son promise:—"The Engineer's Year-book of Formulæ, Rules, Tables, Data and Memoranda in Civil, Mechanical, Electrical, Marine and Mine Engineering," by H. R. Kempe, illustrated; and new editions of "The Art of Soap-making: a Practical Handbook of the Manufacture of Hard and Soft Soaps, Toilet Soaps," by Alexander Watt, illustrated; "Pumps and Pumping, a Handbook for Pump Users, being Notes on Selection, Construction and Management," by M. Powis Bale; "Gas-Engine Handbook, a Manual of Useful Information for the Designer and the Engineer," by E. W. Roberts; "The Construction of Roads and Streets," by the late Henry Law and D. K. Clark.

Messrs. Longmans and Co.'s list includes:—"My Autobiography," by Prof. F. MaxMüller; "Researches on Cellulose, 1895-1900," by Cross and Bevan; "Human Personality, and its Survival of Bodily Death," by Frederic W. H. Myers, two vols.; "Dissertations on Leading Philosophical Topics: being Articles Reprinted from *Mind*," by Dr. Alexander Bain; "A Practical Treatise on Mine Surveying," by Arnold Lupton, illustrated; "Pianoforte Tone Production," by Prof. T. Matthay; "Twentieth Century Inventions: a Forecast," by George Sutherland.

Messrs. Macmillan and Co.'s science list comprises:—"The Cambridge Natural History," vol. viii., Amphibia and Reptiles, by Dr. H. Gadow, F.R.S.; "The Scientific Memoirs of Thomas Henry Huxley," edited by Prof. Sir M. Foster, K.C.B., F.R.S., and Prof. E. Ray Lankester, F.R.S., in 4 vols., vol. iii.; "Diseases in Plants," by Prof. H. Marshall Ward, F.R.S.; "The Problem of Conduct, a Study in the Phenomenology of Ethics," by A. E. Taylor; Macmillan's "A Manual of Medicine," edited by Dr. W. H. Allchin, vol. iii.; and new editions of "The Scenery of Scotland viewed in connection with its Physical Geology," by Sir Archibald Geikie, F.R.S., illustrated; "The Methods of Ethics," by the late Prof. Henry Sidgwick, with portrait; "Introduction to Physical Chemistry," by Prof. James Walker; "Flowers and Ferns in their Haunts," by M. O. Wright, illustrated; "Dictionary of Philosophy and Psychology," 3 vols., edited by Prof. J. M. Baldwin; "The Limits of Evolution," by Prof. G. H. Howison; "School Hygiene," by Dr. E. R. Shaw; "The New Basis of Geography," by J. W. Redway; "Ethics, Descriptive and Explanatory," by Prof. S. E. Mezes; "Cyclopedia of American Horticulture," edited by Prof. L. H. Bailey, vol. iii., illustrated; "The Principles of Stock-Breeding," by Prof. W. H. Brewer; "Farm Poultry," by Prof. G. C. Watson, illustrated; "The Principles of Feeding Animals," by W. H. Jordan; "A Laboratory Manual in Physics," by Drs. Crew and Tatnall; "Elementary Electricity and Magnetism," by Profs. D. C. and J. P. Jackson; "Plane and Solid Geometry," by Prof. A. Schultze and F. L. Sevenoak; "Elementary Geometry," by Prof. T. F. Holgate; "The Röntgen Rays in Medicine and Surgery," by Dr. F. H. Williams, illustrated; "Surgical Technique," by Drs. von Esmarch and Kowalzig (translated), illustrated.

Messrs. Methuen and Co. give notice of:—"The Natural History of Selborne," by Gilbert White, edited by Prof. L. C. Miall, F.R.S., and W. Warde Fowler; "Diseases of the Heart," by Dr. E. H. Colbeck, illustrated.

Mr. John Murray's list includes:—"The Native Races of South Africa: their Economic and Social Condition," by the South African Native Races Committee, with maps; "The Life of Gilbert White, of Selborne, based on letters, journals, and other documents in the possession of the family, and not hitherto published," by his Great Grand-Nephew, Rashleigh Holt-White, 2 vols., illustrated; "The Natural History of Religion, based on the Gifford Lectures delivered in Aberdeen in 1889-90 and 1890-91," by Prof. Edward Burnett Tylor, F.R.S., illustrated; "The Book of Ser Marco Polo, the Venetian," translated and edited by the late Colonel Sir Henry Yule, revised throughout in the light of modern discoveries, with a memoir of Colonel Yule," by Prof. Henri Cordier, 2 vols., illustrated; "Heredity," by Prof. J. Arthur Thomson,

illustrated; "The Dawn of Modern Geography, a history of exploration and geographical science from the opening of the Tenth to the middle of the Thirteenth Century, A.D., 900–1250," by C. Raymond Beazley, illustrated; "Dangerous Trades, the historical, social and legal aspects of industrial occupations as affecting public health," by a number of experts, edited by Dr. T. Oliver, illustrated; "The Gypsies of Spain, their Manners, Customs, Religion and Language," by A. Wallis Mills, illustrated.

Mr. J. C. Nimmo promises:—A new edition of "A Handbook of British Birds, showing the distribution of the Resident and Migratory Species in the British Islands, with an Index to the Records of the Rarer Visitants," by J. E. Harting, illustrated.

Mr. David Nutt calls attention to translations of:—"The Realms of the Dead in Ancient Egypt," by Prof. Alfred Wiedemann; "The Tell-el-Amarna Tablets," by Dr. C. Niebuhr; "The Babylonian and Hebrew Genesis," by Prof. H. Zimmern; "The Babylonian Conception of Heaven and Hell," by Dr. Alfred Jeremias; "The Political Development of Babylonia and Assyria," by Prof. H. Winckler.

Messrs. Kegan Paul and Co., Ltd., announce:—"The Origin of Thought," by Rev. D. Nickerson; "Arsenic," by Prof. J. A. Wanklyn.

Messrs. G. P. Putnam's Sons' announcements include:—"The Method of Evolution," a review of the present attitude of science toward the question of the laws and forces which have brought about the origin of species, by H. W. Conn, illustrated; "Care of the Consumptive," a consideration of the scientific use of natural therapeutic agencies in the prevention and cure of consumption, together with a chapter on Colorado as a resort for invalids, by Dr. Charles Fox Gardiner; and a new edition of "Thinking, Feeling, Doing," by E. W. Scripture, illustrated.

In the announcements of Messrs. Lovell Reeve & Co., Ltd., we notice:—"Flora Capensis," the continuation edited by Sir W. T. Thiselton-Dyer, F.R.S., vol. vi., part 1; "Flora of Tropical Africa," the continuation edited by Sir W. T. Thiselton-Dyer, F.R.S, vol. viii., part 1; "Monograph of Membracidæ," by George Bowdler Buckton, F.R.S.; "The Hepaticæ of the British Isles," by W. H. Pearson, parts 1 to 17; "The Lepidoptera of the British Islands," by Charles G. Barrett, part 79; "Lepidoptera Indica," by F. Moore, part 49; "Teracolus, a Monograph of the Genus," by E. M. Bowdler Sharpe, part 9.

Messrs. Walter Scott, Ltd., announce:—"The Mediterranean Race," by Prof. Sergi; and new editions of "Hypnotism," by Dr. A. Moll; "The Criminal," by H. Ellis; "The Evolution of Sex," by Profs. P. Geddes and J. A. Thomson; and "The Psychology of Religion," by Prof. Starbuck.

In the list of Messrs. Smith, Elder and Co., we see:—"Surgical Experiences in South Africa, 1899–1900, being mainly a Clinical Study of the Effects of Injuries produced by Bullets of Small Calibre," by George Henry Makins, illustrated.

The S. P. C. K.'s list includes:—"British and Garden Poisonous Plants," by Rev. Prof. Henslow.

Messrs. Swan Sonnenschein and Co., Ltd., announce:—"The Romance of the Heavens," by Prof. A. W. Bickerton, illustrated; "Phenomenology of the Spirit," by G. W. F. Hegel, translated by J. B. Baillie; "The Elements of Embryology, Man and Mammals," by Dr. O. Hertwig, translated and edited by Dr. E. L. Mark and H. W. Rand; "The Specious Present: a Metaphysical Treatise," by Alfred Hodder; "Student's Text Book of Zoology," by Adam Sedgwick, F.R.S., vol. ii., illustrated; "The Wonderful Century Reader," by Dr. Alfred Russel Wallace, F.R.S., illustrated; "Biological Types in the Vegetable Kingdom," by Wilfred Mark Webb; "Ethics," by Prof. W. Wundt, vol. iii.:—The Principles of Morality and the Sphere of their Validity, translated and edited by Prof. E. B. Titchener; "Physiological Psychology," by Prof. W. Wundt, translated from the fourth German edition by Prof. E. B. Titchener. 2 vols; "Aristotle's Psychology," translated and edited, &c., by Prof. W. A. Hammond; "History of Contemporary Philosophy," by Dr. Max Heinze, translated by Prof. W. Hammond; "The Life of the Sea Shore," by M. Newbiggin, illustrated; "Text-Book of Palæontology for Zoological Students," by T. T. Groom, illustrated; "Mammalia," by Rev. H. A. Macpherson; "Birds' Eggs and Nests," by W. C. J. R. Butterfield, and a new edition of "Evolution and its bearing on Religions," by A. J. Dadson.

The Science announcements of the University Tutorial Press are:—"First Stage Practical Plane and Solid Geometry"; "First Stage Machine Construction and Drawing"; "First Stage Building Construction," by Brysson Cunningham; "Mathematics, First Stage," Edited by Dr. Wm. Briggs; "First Stage Physiology"; "Section One Physiography"; "Key to Mechanics of Solids, First Stage," by F. Rosenberg; "Advanced Hygiene," by A. E. Ikin and R. A. Lyster; "The Tutorial Algebra," part i., Elementary Course, by Rupert Deakin; "The Tutorial Arithmetic," by W. P. Workman; "Deductions in Euclid," by T. W. Edmondson.

Mr. T. Fisher Unwin announces:—"In Tibet and Chinese Turkestan," by Captain H. H. P. Deasy, illustrated; "By Rock and Pool," by Louis Becke.

Mr. P. Wellby gives notice of:—A new edition of "Psychic Philosophy as the Foundation of a Religion of Natural Law," by V. C. Desertis.

Messrs. Whittaker's list is as follows:—"Electric Traction," by J. H. Rider; "Electric Lighting and Power Distribution," by W. Perren Maycock, vol. ii.; "Galvanic Batteries," by S. R. Bottone; "Telephone System of the British Post Office," by T. E. Herbert.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The subject for the Sedgwick Prize, 1903, is "The Petrology of some Group of British Sedimentary Rocks."

A John Lucas Walker Studentship in Pathology, of the value of £200 a year for three years, will shortly be filled up. Candidates, who need not be members of the University, are to apply to Prof. Woodhead, Pathological Laboratory, by April 16.

Mr. A. W. Hill and Mr. C. E. Inglis have been elected to fellowships at King's College. Mr. Hill took first classes in the Natural Sciences Tripos, 1897-98; Mr. Inglis was 22nd Wrangler, 1897, and first class Mechanical Sciences Tripos, 1898.

DR. KOHN, of University College, Liverpool, has been elected Principal of the new Sir John Cass Technical Institute, Aldgate.

THE Senate of the University of Aberdeen have decided to confer the honorary degree of LL.D. upon Prof. Virchow, of Berlin, Major Alfred W. Alcock, Superintendent of the Indian Museum, Calcutta, and Professor of Zoology in the Medical College of that city, and Dr. Angus Fraser, of Aberdeen.

THE celebration of the ninth jubilee of the University of Glasgow will begin on June 12, and will occupy three or four days. The details of the programme have not yet been arranged, but we understand that the celebration will probably include a religious service in the Cathedral, public reception of delegates and addresses from Universities and learned societies, a graduation ceremony, conversazione in the Bute Hall, banquet in the City Chambers, garden party in the Botanic Gardens, and a smoking concert. If the weather is fine there will also be an excursion down the Clyde by steamer.

SCIENTIFIC SERIALS.

American Journal of Science, March.—Circular magnetisation and magnetic permeability, by John Trowbridge and E. P. Adams. The experiments of Klemenčič upon the intensity of magnetisation produced by an oscillatory current in an iron wire, showed that for a frequency of 9×10^7 oscillations per second the permeability of iron to oscillatory currents is a constant. In the present paper the oscillation frequencies are much lower, ranging from 600 to 3000, and in this case the permeability is not a constant, but depends upon the strength of the magnetic field; that is, the iron behaves towards oscillatory currents in much the same manner as it does towards steady currents.—Notes on the geology of parts of the Seminole, Greek, Cherokee, and Osage nations, by C. N. Gould. A line of coal beds extends north and south near Bartlesville, Skiatook, Dawson, Tulsa, Okmulgee, and Henryville. There is no reason to doubt that gas and oil will eventually be found near these coal beds.—Names for the formations of the Ohio coal measures, by C. S. Prossner.—A new American species of Amphicyon, by J. L. Wortman.

A description of a palatal portion of a skull from the Loup Fork Miocene deposits of Nebraska, named *Amphicyon americanus*, which is undoubtedly to be referred to the European genus. All the Amphicyons of the American Tertiary hitherto described belong to genera quite different and distinct from the typical genus *Amphicyon* of Europe.—Studies in the Cyperaceæ, by T. Holm. *Carices* (*Vigneae*) *astrostachyae*.—A just intonation piano, by S. A. Hageman. A description of a piano mechanism for giving just intonation as opposed to equal temperament.—Very on atmospheric radiation, by W. Hallock.

Annalen der Physik, February.—The electromagnetic rotation experiment and unipolar induction, by E. Hagenbach. Lecher has described some results which have led him to regard the usual text-book explanations of many rotation experiments as fallacious. The experimental results here given are in complete accordance with the values calculated from the Biot-Savart laws, and, in fact, the fundamental experiment of Lecher furnishes an additional proof of their accuracy.—On the law of radiation of black substances, by F. Paschen. A comparison of the theories of Planck and Wein with experiment.—A new determination of the dispersion of fluorspar in the ultra-red, by F. Paschen.—The determination of the selective capacity for reflection of a plane mirror, by F. Paschen.—On the behaviour of liquid dielectrics on the passage of an electric current, by E. v. Schweidler. The results obtained show that the analogy between the behaviour of ionised gases and liquid dielectrics is not an accidental one, but is based upon the phenomena of discharge.—On the testing of the magnetic properties of steel, by I. Klemenčič.—Determination of the frequency of an alternating current, by R. Wachsmuth. The method described, which is very convenient for vibrations between 1 and 100 per second, ceases to be of service when the number rises above 150.—On the temperature in Geissler's tubes, by K. Kerkhof. The temperature in the capillary tube of a Geissler tube was measured by means of the change of resistance of a fine platinum wire. The results were not in agreement with Wiedemann's law, that the temperature is inversely proportional to the section of the tube.—Magnetic images, by H. Jaeger.—The experimental determination of the capillary constants of condensed gases, by L. Grunmach. The method used is based upon the production of capillary waves by the prongs of a tuning fork and the application of a formula developed by Lord Kelvin. It had been found previously to yield satisfactory results with ordinary liquids and molten metals, and has worked well with liquefied gases. Results are given for sulphur dioxide, ammonia, Pictet's liquid and chlorine. The application of the formula of Ramsay and Shields to these observations proves that there is no association of the molecules in liquid ammonia and sulphur dioxide. In the case of chlorine there appears to be a certain amount of association.—The motion of an electrified particle in an electrostatic field, by E. Riecke.—On stratification in a stream of electrified particles, by E. Riecke.—On the ionisation of electrified gases and the unipolar discharge in glowing bodies, by J. Stark.—On the thermoelectrical behaviour of some oxides and metallic sulphides, by E. van Aubel. The results do not confirm the researches of Abt on the same subject.—On the molecular heat of compound bodies and the Neumann-Joule-Kopp law, by E. van Aubel.—On the theory of radiation. A reply to the criticism of Planck, by W. Wien.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, February 28.—"On the Structure and Affinities of Fossil Plants from the Palæozoic Rocks. IV. The Seed-like Fructification of *Lepidocarpon*, a Genus of Lycopodiaceous Cones from the Carboniferous Formation." By D. H. Scott, M.A., Ph.D., F.R.S., Hon. Keeper of the Jodrell Laboratory, Royal Gardens, Kew.

A short account of the new genus *Lepidocarpon* has been given in a note communicated to the Royal Society last August [1]; the present paper contains a full, illustrated description of the fossils in question, together with a discussion of their morphology and affinities.

The strobilus of *Lipidocarpon Lomaxi*, the Coal-measure species, is, in its earlier condition, in all respects that of a *Lepidostrobus*, of the type of *L. Oldhamius*.

[1] "Note on the Occurrence of a Seed-like Fructification in certain Palæozoic Lycopods," *Roy. Soc. Proc.*, vol. lxvii. p. 306.

In each megasporangium, however, a single megaspore or embryo sac alone came to perfection, filling almost the whole sporangial cavity, but accompanied by the remains of its abortive sister-cells. An integument ultimately grew up from the sporophyll, completely enclosing the megasporangium, and leaving only a narrow slit-like opening, or micropyle, along the top. As shown in specially favourable specimens, both of *Lepidocarpon Lomaxi* and of *L. Wildianum*, the more ancient Burntisland form, the functional megaspore became filled by a large-celled prothallus, resembling that of the recent *Isoëtes* or *Selaginella*. The whole body, consisting of the sporophyll, bearing the integumented megasporangium and its contents, became detached from the strobilus, and in this isolated condition is identical with the "seed" described by Williamson under the name of *Cardiocarpon anomalum*, which, however, proves to be totally distinct from the Cordaitean seed so named by Carruthers.

The seed-like organs of *Lepidocarpon* are regarded by the author as presenting close analogies with true seeds, but as differing too widely from the seeds of any known Spermophyta to afford any proof of affinity. The case appears rather to be one of parallel or convergent development, and not to indicate any genetic connection between the Lycopods and the Gymnosperms, or other Phanerogams.

"On the Theory of Consistence of Logical Class-frequencies and its Geometrical Representation." By G. Udny Yule, formerly Assistant Professor of Applied Mathematics in University College, London. Communicated by Prof. K. Pearson, F.R.S.

Geological Society, February 20.—J. J. H. Teall, F.R.S., president, in the chair.—Prof. J. B. Harrison, alluding to a series of views of parts of the interior of British Guiana, which he laid on the table, remarked that the photographs had been taken by his colleague, Mr. H. I. Perkins, Acting Commissioner of Mines in British Guiana, during their recent geological investigations into the structure of the goldfields of that colony. The views well illustrate the general characteristics of the densely wooded country in which the gold-bearing areas occur, and give some idea of the difficulties which affect the work of the mining prospector and of the field-geologist in that colony. Several of the photographs illustrate rapids, cataracts and falls which so frequently occur along the courses of some of the vast rivers of that part of South America, and show the differing forms of weathering of various igneous rocks and of horizontally-bedded sandstones and conglomerates in the tropics. With reference to a few rock-specimens exhibited, Prof. Harrison stated that they were of diamond-drill cores from the Omai Creek claims on the Essequibo River, and that they fairly represented the principal auriferous rocks of that district. Omai Creek is a small stream flowing into the Essequibo at about 130 miles above its mouth, and the country through which it flows is usually diabase (dolerite) and its decomposition-products. From a part of the bed of one of the tributaries of this stream (Gilt Creek), about 500 feet in length by 50 in breadth, some 60,000 ounces of gold and some hundreds of small diamonds have been recovered by the somewhat crude methods of working hitherto in use.—Prof. Edward Hull made a communication, illustrated by lantern slides, on the submerged valley opposite the mouth of the River Congo. The position of this submerged valley has been ascertained by Mr. Edward Stallybrass and Prof. Hull by contouring the floor of the ocean with the aid of the soundings recorded on the Admiralty charts. The sides of the valley are steep and precipitous and clearly defined, the width varying from two to ten miles, and the length across the continental platform being about 122 miles. It is continuous with the valley of the Congo, and its slope is uninterruptedly downward in the direction of the abyssal floor. The steepness of the sides indicates that they are formed of very solid rocks. Several other submerged valleys off the coast of Western Europe were described for comparison. In most cases the landward end of the submerged river-channel is filled with silt, &c., for some distance from the mouth of the actual river; but farther out its course becomes quite distinct towards its embouchure at the edge of the continental platform. Among the valleys specified were those off the mouth of the Tagus and the Lima, the Adour and the Loire, and those in the English and Irish Channels. The following communication was read:—The geological succession of the beds below the Millstone Grit series of Pendle Hill and their equivalents in certain other parts of England, by Dr. Wheelton Hind and J. Allen Howe. Part i. of this paper

consists of a detailed account of the ground. By various sections the extent of the deposit is shown, and it is demonstrated that the deposit occupies a basin, of which the Pendle district occupies the maximum area of deposit, for the sequence thins out rapidly north-west and south. But although the beds thin out, a calcareous series with a typical zonal fauna is always present. Beds containing this fauna are traced from County Dublin, the Isle of Man, Bolland, Craven, the Calder and Mersey valleys, to Derbyshire and North Staffordshire. It is shown that this series, for which the term Pendleside Series is proposed, occupies a basin about the size of the area indicated above, and that the beds are lithologically distinct from the Yoredale Beds of Wensleydale, and contain a different fauna. Part ii. discusses the question in detail, from a palæontological point of view. The migration of certain families of fossils from the north to the south, brought about by a slow change of environment, is shown by tables, and lines called "isodiectic lines" are drawn to represent this distribution. It is shown that the Nuculidæ are found in the lowest Carboniferous beds in Scotland, but come in at successively higher horizons as the beds range southward. These facts and comparative thicknesses are the basis of an argument as to the local distribution of land and water in Carboniferous times; and it is shown that the peculiar change in type which Carboniferous rocks undergo in passing from north to south is due entirely to physiographical conditions, and not to any theoretical assumption of contemporaneous faulting. It is shown, moreover, that the Craven Faults *per se* have had nothing to do with this change of type. The correlation of the limestone-knolls of Craven with the Pendleside Limestone is demonstrated to be no longer tenable.

Zoological Society, March 5.—Dr. W. T. Blanford, F.R.S., vice-president, in the chair.—Mr. Sclater exhibited, on behalf of Captain Stanley Flower, photographs of a young female giraffe, a young male white oryx (*Oryx leucoryx*), and a male ostrich, with the vocal sac extended, which had been taken from examples living in the Zoological Garden at Ghizeh, Egypt.—There were exhibited, on behalf of Dr. Einar Lönnberg, two photographs of a skull of the musk-ox from East Greenland.—Dr. Smith Woodward read a paper on some remains of extinct reptiles obtained from Patagonia by the La Plata Museum. They included the skull and other remains of a remarkably armoured Chelonian, *Miolania*, which had previously been discovered only in superficial deposits in Queensland and in Lord Howe's Island, off the Australian coast. The genus was now proved to be Pleurodiran. There was also a considerable portion of the skeleton of a large extinct snake, apparently of the primitive genus of the South American family Ilysiidæ. Along with these remains were found the well-preserved jaws of a large carnivorous Dinosaur, allied to *Megalosaurus*. Either the dinosaurian reptiles must have survived to a later period in South America than elsewhere, or geologists must have been mistaken as to the age of the formation in which the other reptiles and extinct mammals occurred. The discovery of *Miolania* in South America seemed to favour the theory of a former Antarctic continent; but it should be remembered that in late Secondary and early Tertiary times the Pleurodiran Chelonians were almost cosmopolitan. Future discovery might thus perhaps explain the occurrence of *Miolania* in South America and Australia, in the same manner as the occurrence of *Ceratodus* in these two regions was already explained.—Mr. R. I. Pocock read a paper containing descriptions of six new species of trap-door spiders from China. One of these, *Haloproctus ricketti*, was remarkable as constituting a new genus of a specialised group of Ctenizidæ, hitherto known only from the Sonoran area of North America. Another, *Latouchia fossoria*, also a new genus, was a more typical Ctenizoid.—Mr. R. H. Burne read a paper on the innervation of the supraorbital canal in the sea-cat (*Chimaera monstrosa*).—Mr. F. E. Beddard, F.R.S., read descriptions of certain new or little-known earthworms belonging to the genera Polytoreutus and Typhœus. Mr. Beddard also described the clitellum and spermatophores in the annelid *Alma stuhlmanni*.

EDINBURGH.

Royal Society, February 18.—Prof. Geikie in the chair.—Dr. Peddie communicated a paper by the late Mr. Shand and himself on the thermoelectric position of solid mercury. The thermoelectric line was found to be nearly parallel to that of iron and to meet the line of copper very near the temperature of $-50°$ C.—Mr. Thomas Heath read a paper on observations of the Edinburgh rock thermometers, in which the observations both of the old and the new sets were fully discussed. There was some doubt about the corrections to be applied to the new set; but treating them in the same way as the old set which had been installed by Prof. Forbes in 1837, but had been broken in 1876 by a madman, Mr. Heath found that the results were fairly consistent. There was evidence of change of conductivity with depth, and the values of the conductivity deduced by him from the harmonic analysis were somewhat smaller than the values deduced by Forbes and Everett from the older observations. The new thermometers, however, had been steadily sinking in position since they had been installed in 1879.

March 4.—Sir Arthur Mitchell in the chair.—Prof. Letts and Mr. J. Hawthorne communicated a paper on the seaweed *Ulva Latissima* and its relation to the pollution of sea water by sewage, in which they had investigated with care the manner of fermentation under various conditions. One of the most remarkable facts about this seaweed is the high proportion of nitrogen, distinctly in excess of what is met in other similar plants, in this respect resembling an animal rather than a plant. *Ulva Latissima* is found in great quantity in certain parts of Belfast Lough and Dublin Bay, where the water is strongly polluted by sewage. In similar situations in Stranford Bay, where there was comparatively little sewage, the weed was rarely met with.—Mr. Aitken, in some further notes on the dynamics of cyclones and anticyclones, discussed the relation between storm tracks and the regions of maximum temperature and maximum humidity. Four facts were mentioned as supporting the theory that cyclones were convectionally driven, namely: (1) the circulation in cyclones is principally towards the centre, (2) the velocity increases towards the centre at all levels, (3) storm tracks form and follow with the season change of the areas over which the supply of hot moist air is most plentiful, (4) the greater violence of winds in cyclones than in anticyclones points to some source of energy in cyclonic areas. —Prof. Copeland, the Astronomer Royal for Scotland, gave an account of the observations of the new star in Perseus, discovered by Dr. Anderson. Since the first night of observation the character of the spectrum of the star had changed greatly, being now a faint continuous spectrum crossed with broad, bright lines, flanked on the more refrangible side with dark absorption bands. No evidence of polarisation could be detected in the bright lines. The star was now on the wane, and would probably gradually diminish in brightness until it ceased to be visible to the naked eye. In the after discussion Dr. Knott pointed out how the distribution of the bright and dark bands fell in with the view that the phenomenon was due to a collision taking place mainly in the line of sight, the later stages requiring the relative displacement towards us of gaseous products, cooling by their expansion.

MANCHESTER.

Literary and Philosophical Society, March 5.—Prof. Horace Lamb, F.R.S., president, in the chair.—Mr. C. E. Stromeyer referred to the results of a study of tidal waves which he had published in NATURE in 1895, and which indicated that in the majority of cases of which records were available the tidal waves appeared to proceed from the Faraday Reef. Particulars of the tidal wave which recently struck the *Teutonic* are not yet to hand for comparison with former records.—Mr. W. E. Hoyle read a paper entitled "On the genera Octopus, Eledone and Histiopsis," in which he dealt with the nomenclature of these genera.

PARIS.

Academy of Sciences, March 11.—M. Fouqué in the chair.—Utilisation of the points of Collins for the determination of a quadrilateral, by M. Hatt.—On the complete synthesis of acetylpropylene and the terpenic hydrocarbons, by M. Berthelot. Propylene and acetylene, mixed in equal volumes, are heated together to about 500° C. The hydrocarbon C_5H_8 is formed, together with methane.—Remarks on my last communication relating to the telegraphic and telephonic lines established on the snow of Mont Blanc, by M. J. Janssen.—On the waves of the second order, with respect to the velocities which may be presented by a viscous fluid, by M. P. Duhem.—Maltosuria in certain diabetics, by MM. R. Lépine and Boulud. The difference between the rotatory power and the copper-reducing power in the case of certain urines from diabetic patients can be explained by the assumption that maltose is present as well as

glucose.—Remarks by M. Edmond Perrier, on the scientific expeditions of the *Travailleur* and *Talisman*.—M. A. Normand was elected a correspondant for the Section of Geography and Navigation in the place of M. Alexis de Tillo.—Remarks by M. Darboux on the death of M. Th. Moutard.—On the variability of the planet *Eros*, from negatives taken at the Observatory of Toulouse, by M. L. Montangerand (see p. 502).—Note concerning the preceding observations of M. Montangerand, by M. Baillaud.—Complementary details on the new star in Perseus, by M. H. Deslandres. The results of the spectroscopic study of the new star do not confirm the hypothesis tentatively put forward in a previous note. It appears to be necessary to assume the existence of at least two stars, one of which is perhaps a nebula, and which is approaching the other with an enormous velocity.—Observations on the sun made at the Observatory of Lyons with the Brunner 16 cm. equatorial during the fourth quarter of 1900, by M. J. Guillaume. The results are summarised in three tables, giving the number of spots, their distribution in latitude, and the distribution of the faculæ in latitude.—On a certain category of transcendental functions, by M. Edmond Maillet.—On the regular quaternary groups of a finite order, by M. Léon Autonne.—On an electrophone giving very loud sounds and on the causes which produce it, by M. Th. Tommasina.—On the reduction of sulphomolybdic acid by alcohol, by M. E. Péchard. Molybdic acid, dissolved in sulphuric acid and gradually reduced by alcohol, gives a blue crystalline deposit of complicated composition, approximately $5NH_3MoO_2SO_3.7MoO_3+8H_2O$.—A new glycol, 1-4 butane-diol, or tetramethyleneglycol, and its diacetin, by M. J. Hamonet. The diacetin is prepared by the action of silver acetate upon the di-iodobutane, and the glycol is obtained from this by heating with dilute lime-water.—The action of zinc powder upon the saturated fatty acids, by M. A. Hébert. Stearic acid, heated with zinc dust, gives a complicated mixture of olefines, the bromides of which were examined.—The action of mercuric oxide upon some organic compounds, by MM. A. Lumière, L. Lumière and F. Perrin.—On a new preparation of terpinol, by M. P. Genvresse. Pinene, dissolved in alcohol, is treated with nitrous acid, distilled with steam and the product purified by fractional distillation in a vacuum.—New characters of the short electrical stimulus transmitted by the nerve, by M. Aug. Charpentier.—Contribution to the psycho-physiological study of the vital acts in the total absence of the brain in an infant, by MM. N. Vaschide and Cl. Vurpas. The infant, which survived thirty-nine hours, showed a notable lowering of temperature and remarkably slow breathing of the type described by Cheyne and Stokes. The case demonstrated the *rôle* of the cerebral hemispheres in circulation, respiration and the temperature regulation.—New observations on *Bathyomus*, enormous isopods met with at great depths, by M. E. L. Bouvier.—On the sensibility of the higher plants to very small doses of toxic substances, by M. Henri Coupin. The higher plants, like the fungi, are so sensitive to the toxic action of certain metals, notably silver, mercury, copper and cadmium, that they give evidence of their presence in quantities too small to appreciate by chemical analysis.—Anatomical researches on the ripening of the shoots of the vine, by M. Kövessi. The branches ripen better as the cellular thickness of their walls increases and as their cells contain more starch.—On a fossil insect found in the Trias of Lorraine, by M. P. Fliche.—On the periods of the southern aurora, by M. Henryk Arçtowski.—Note relating to a lithological and bathymetric atlas of the coasts of France, by M. J. Thoulet.

DIARY OF SOCIETIES.

THURSDAY, MARCH 21.

ROYAL SOCIETY, at 4.30.—Studies in Visual Sensation (Croonian Lecture): Prof. C. Lloyd Morgan, F.R.S.

LINNEAN SOCIETY, at 8.—On the Intestinal Tract of Birds, and the Valuation and Nomenclature of Zoological Characters: P. Chalmers Mitchell.

CHEMICAL SOCIETY, at 8.—Researches on Morphine, Part II: S. B. Schryver and F. H. Lees.—The Constitution of Pilocarpine, Part II.: H. A. D. Jowett.—Note on the Latent Heats of Evaporation of Liquids: Holland Crompton.—(1) Action of Dry Silver Oxide and Ethyl Iodide on Benzoylacetic Ester, Desoxybenzoin, and Benzyl Cyanide; (2) Alkylation of Acylarylamines: G. D. Lander.

CAMERA CLUB, at 8.15.—Yorkshire Caves and Waterfalls: T. C. Hepworth.

FRIDAY, MARCH 22.

ROYAL INSTITUTION, at 9.—Some Recent Work on Diffusion: Dr. Horace Brown, F.R.S.

PHYSICAL SOCIETY (University College, Gower Street), at 5.—On the Expansion of Silica: Prof. Callendar, F.R.S.—The Spectroscopic Apparatus at University College: Dr. E. C. C. Baly.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Hunslet Railway and Bridge over the River Aire: O. L. McDermott.

SATURDAY, MARCH 23.

ROYAL INSTITUTION, at 3.—Sound and Vibrations: Lord Rayleigh, F.R.S.

MONDAY, MARCH 25.

SOCIETY OF ARTS, at 8.—Electric Railways: Major P. Cardew.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—Journeys in the Linyanti Region, South Africa: Percy C. Reid.—Exploration and Survey in the Sobat Region: Major H. H. Austin, R.E.

INSTITUTE OF ACTUARIES, at 5.30.—On the Rates of Mortality in New South Wales and Victoria, and the Construction of a Mortality Table from a single Census and the Deaths in the Years adjacent thereto: E. McMahon Moors and W. R. Day.

CAMERA CLUB, at 8.15.—Colour Photography by the Sanger-Shepherd Process: A. Pringle.

TUESDAY, MARCH 26.

ROYAL INSTITUTION, at 3.—The Cell as the Unit of Life: Dr. A. Macfadyen.

INSTITUTION OF CIVIL ENGINEERS, at 8.—*Paper to be further discussed*: The Æsthetic Treatment of Bridge Structures: J. Husband.—*Paper to be read, time permitting*: The Burrator Works for the Water-supply of Plymonth: E. Sandeman.

ROYAL PHOTOGRAPHIC SOCIETY, at 8.—Some Improvements in Optical Projection: J. H. Agar Baugh.

WEDNESDAY, MARCH 27.

THURSDAY, MARCH 28, 1901.

THE BOOK OF ANTELOPES.

The Book of Antelopes. By P. L. Sclater and O. Thomas. 4 vols. Illustrated. (London: Porter, 1894–1900.) Price, 13*l.* 10*s.* net.

IT was the intention of the late Sir Victor Brooke, who for many years of his life devoted a large amount of time and attention to the study of the ruminants generally, to write an illustrated monograph of that interesting and beautiful, although ill-defined, section of them commonly known as antelopes. And with this end in view he instructed the late Mr. Joseph Wolf to prepare a number of coloured sketches of these animals, which were in due course transferred to stone, printed off, and coloured by hand. A considerable bulk of manuscript was also written by Sir Victor; but, for some reason or another, the work was never brought to anything like completion during his lifetime.

And perhaps it was fortunate for science that the material thus accumulated was left in this unfinished state. For the opening-up of Somaliland and East Africa in general, as well as continued exploration in the heart of the continent, have of late years made us acquainted with quite a number of antelopes which were altogether unknown, or but very imperfectly known, to Sir Victor Brooke, so that if the work had been published during his lifetime it would necessarily have been extremely incomplete and imperfect.

By the generosity of Sir Victor's executors the whole of these drawings, plates and manuscript were unreservedly placed at the disposal of the senior author of the splendid volumes before us, who for many years had made constant endeavours to increase our knowledge of the antelopes of Africa, and by whom many remarkable new types had been brought to the notice of the zoological world. As the work would have been too heavy for a man with as many calls on his time as has the secretary of the Zoological Society to carry out alone, Mr. Sclater secured the assistance of Mr. Thomas, of the British Museum. Such additional plates as were necessary to complete the series of the more striking types of antelopes were duly put in hand and completed. And the result of this happy union of forces has been, after several years of arduous labour, to produce a work the like of which has never before been seen, and which will remain a monument alike of the ability and industry of its authors and of a group of lovely animals which are only too rapidly and too surely disappearing for ever before the advance of an all-devouring civilisation.

Despite the fact that the new sketches lack the inimitable touch characteristic of Wolf's animal pictures, they accord fairly well with lithographic reproductions of the latter, and in certain instances are their superior in truthfulness to nature. For in sketches of this description there is always a danger lest fidelity to the model should be sacrificed to artistic effect, an instance in point occurring in the case of Mrs. Gray's waterbuck of the White Nile.

Although coloured figures of a number of the more striking South African antelopes appeared in the well-known sporting work by the late Sir Cornwallis Harris, while Dr. Gray, in the British Museum "Catalogue of Ruminant Animals," published in 1872, gave a complete list of the species then known to him, no fully illustrated monograph of this group of ruminants has, we believe, ever previously been published—at least in this country—so that the authors have the field practically to themselves. In Gray's Catalogue a total of 101 species of these animals were recognised, of which no less than 81 are African; but in a "Hand-list" published a year later the number was reduced to 98, owing to three of the African names having been found to be synonyms of others. In the present monograph, the authors, apart from a few described during the progress of the work, recognise a total of no less than 133 distinct species, about 120 of which are African. It is true that certain of these so-called species might be regarded by other naturalists (now possibly in some instances by the authors themselves) in the light of local races; but, even making allowance for such possible reductions, the increase in the number of well-established species of these animals since the date of Gray's last list is very noteworthy, and bears eloquent testimony to the energy with which African zoology has been worked up of late years. As the great majority of these new species have been described by one or other of the authors, it was only right and proper that the task of monographing the entire group should have fallen to their lot.

Although most of us have a general and vague idea of what constitutes an "antelope," yet it is somewhat remarkable that the group of animals thus designated is one that does not admit of accurate limitation or definition. Some, for instance, might consider that the chamois and the so-called white goat of the Rocky Mountains were entitled to be included in the group; but this is not the view held by the authors of the present monograph. As a matter of fact, the term is only a vague designation for a number of more or less distinct groups of hollow-horned ruminants which come under the designation neither of cattle, sheep nor goats; and in reality there ought to be a distinct English group-name for each subfamily into which "antelopes" are subdivided by our authors. But we must take things as we find them, and such subdivisions being impossible in colloquial language, we cannot do better than agree to employ the term "antelopes" in the sense in which it is used by the authors; that is to say, as indicating the animals treated of in this work, and no others.

As they have occasion to use it so frequently, it is perhaps a little remarkable that the authors have apparently made no attempt to trace the origin and derivation of the word "antelope." So far as can be determined it appears, however, to trace its origin, through the Latin, to *Pantholops*, the old Coptic, and *Antholops*, the late Greek name of the fabled unicorn. Its adoption by the languages of Europe cannot apparently be traced further back than the fourth century of our era, at which date it was employed to designate an imaginary animal living on the banks of the Euphrates. By the earlier English naturalists, and afterwards by Buffon, it was, however, applied to the Indian blackbuck, which is thus entitled to rank as *the* antelope. It follows that the subfamily typified by this species, in which are included the

Z

gazelles, is the one to which alone the term antelopes should be applied if it were employed in a restricted and definable sense.

In their classification, the authors follow in the main the divisions sketched out by Sir Victor, although they have somewhat increased the number of sections, or subfamilies, into which this assemblage of ruminants is split up. Into the limits of such sections it is quite unnecessary to enter upon the present occasion, as it is into any details with regard to species. In the main the characters of most of the species have been drawn from the magnificent series of skins in the British Museum; and where this is the case no emendation on the diagnosis given by the authors is ever likely to be required. In a few instances, however, the Museum was possessed of only very inadequate material at the date when the descriptions were written, so that in these cases there is room for revision. An instance in point is afforded by the white-eared kob of the swamps of the Upper Nile, complete specimens of which have recently been presented to the Museum. By means of these it has been ascertained for the first time that the old bucks of this handsome species are deep black, at least during the pairing season.

Nomenclature, again, is a subject on which some change of opinion has taken place among naturalists during the period in which this work has been in progress. And it is probable that one at least of its authors would not now be prepared to defend the use of all the technical names therein employed.

Although the authors have to deplore the vast decrease that has taken place in the numbers of so many species of African antelopes, in only one instance (that of the blaauwbok) have they to lament complete extermination, and that is not chargeable to the present, or even to the last two or three generations. They record, however, that several species in South Africa are only kept in existence by special protection; and in this connection it may be observed that the effect of the present troubles in that region on these dying species must be watched with the utmost anxiety by all naturalists.

As regards the manner in which the descriptions of the various genera and species are drawn up, the reputation of the authors is a sufficient guarantee that this is, in the main, beyond criticism. And no effort appears to have been spared in order to acquire as much information as possible with regard to geographical distribution. As neither of the authors (except, perhaps, the junior in his youthful days) is acquainted with the animals described in their native wilds, recourse has been necessitated to the writings of others; and the authors may be congratulated that in most instances they have had the courage to give these borrowed accounts in their original guise, instead of endeavouring to conceal their source by paraphrasing.

In one respect, and in one respect only, is there cause for regret in connection with this undertaking, namely, that the authors have not seen fit to refer, or at least in any detail, to the comparatively little that is known in relation to the past history of the group of which they so ably treat. The description and definition of species (even if they be the chief points of interest to sportsmen) are most important, but they are, and can be, only comparatively insignificant features in the philosophical study of animal life and its meaning. One of the burning questions of the day (in zoological circles) is the origin of the Ethiopian fauna; whether it is endemic in the land from which it takes its name, or whether it is due to an immigration from more northern climes. As remains of species closely allied to the giraffes and antelopes of modern Africa are met with in the later Tertiary deposits of India, Persia and Greece, it is obvious that the groups mentioned have much connection with the solution of this important problem. It is, therefore, greatly to be regretted that the authors have not seen fit to give their own views on this point, so far as the evidence to be derived from antelopes is concerned, or, at all events, that they have not informed their readers that several of the genera of these animals, now restricted to Ethiopian Africa, formerly enjoyed a much more extensive geographical range.

In the prospectus to the work it is stated that the authors "are desirous of making the book interesting and instructive to the naturalist, sportsman and general reader." While maintaining throughout a high standard of scientific excellence, and refraining from lowering their style by the inclusion of so-called purely "sporting" accounts, which are only too frequently most wearisome and distasteful to the cultured reader, the authors may be congratulated on having succeeded in their intentions in a manner deserving of the heartiest commendation on the part of all to whom this splendid and monumental work appeals.

R. L.

THE SCIENCE OF ORE DEPOSITS.

Lehre von den Erzlagerstätten. By Dr. Richard Beck. ii Theil. Pp. ix–xviii + 385–724. (Berlin: Borntraeger, 1901). Mk. 8.50.

WE are thankful to find that Dr. Beck has not kept us waiting an unduly long time for the concluding portion of his valuable work, the first instalment of which was recently reviewed in these pages (see p. 245 January 10). The first part brought the description of the different classes of mineral deposits nearly up to the end of Fissure Veins; this subject is now brought to a conclusion with a number of general observations on this important group of ore deposits, the only criticism upon which need be that their limitations are somewhat too narrowly drawn. Most of the phenomena here described, such as the formation of gossans, enrichment or impoverishment of ores in depth, effects upon the surrounding "country," &c., are by no means confined to fissure veins, but are common to all classes of mineral deposits, depending as they do essentially upon the chemical composition of the mineral contents of the deposit, and either not at all or only in very remote degree upon its genetic relations or morphological features. The alterations and oscillations of mineral constitution that many veins show in depth are well but briefly described, although, perhaps, their close connection in many cases with changes in the country rock is hardly enough insisted on. It is almost certain that the well-known change in depth in the silver and copper contents of the Montana copper deposits is purely a

secondary phenomenon, and Dr. Beck is most probably in error when he ranks this among the primary modifications of ore deposits. The description of secondary alterations of deposits and the formation of gossans is extremely good, the chemical investigation of the subject being especially convincing. It must be noted that Dr. Beck only refers under this head to secondary changes above the permanent water-level (in the region of Pošepny's vadose circulation) and not to the phenomena which have recently attracted so much attention in America, and which, under the head of Secondary Enrichment of Ore Deposits, have been so ably investigated by Emmons, Weed and others; these Dr. Beck appears to omit entirely.

The section on the alteration of the wall rocks of mineral veins either by the influence of these veins themselves or by the agencies that have played an important part in the deposition of the mineral constituents of these veins, is a valuable summary of a very important subject, which has only in comparatively recent years attracted the attention that it deserves.

Coming next to the classification of other mineral deposits, or as Dr. Beck rather awkwardly designates them, "Not vein-like epigenetic ore deposits within stratified rocks," the subdivision is far from satisfactory. They are divided, first of all, as follows:—

A. Epigenetic ore beds.
B. Epigenetic ore masses.
C. Contact-metamorphic ore deposits.
D. Ore-bearing fillings of cavities.

Unfortunately, the first group contains many deposits that are generally looked upon as typical masses, *e.g.* the lenticular masses of cupriferous pyrites of the Huelva region. The group is subdivided into deposits occurring in crystalline strata and deposits in non-crystalline strata formed by impregnation, each class being then again subdivided according to its mineral contents. This classification is unfortunate, as it causes the author to describe the above-mentioned pyrites deposits as produced by impregnation; it would hardly be possible to assign a less probable genesis to such deposits as these, consisting as they do mainly of dense massive pyrites practically free from gangue, and it seems impossible to imagine that any one who has ever studied these deposits can seriously believe that they owed their origin to impregnation. It is in any case most unlikely that a system of classification that forces these deposits and the Norwegian and other similar pyrites deposits into different groups, and that takes, moreover, no account of the eruptive rocks with which they are so closely associated, can possibly be correct.

The group of Epigenetic ore masses is a rather more coherent one than its title implies, Dr. Beck confining this group to irregular deposits in calcareous rocks. It is perhaps doubtful whether this is the right place for those very puzzling deposits that are generally spoken of as the gold-bearing "reefs" of Pilgrim's Rest, Lydenburg; it is perhaps more likely that these will prove ultimately to be true bedded deposits, though their real character is to-day far from clear.

The next division of the book contains a short but good description of alluvial deposits; the objections to the independent treatment of this group of deposits have already been pointed out. Apart from these, Dr. Beck's descriptions are thoroughly satisfactory.

The work concludes with a brief but good chapter of general hints upon the search for mineral deposits. In this the author attempts, and with considerable success, to show that the scientific study of mineral deposits can give information of the greatest value to prospectors, and that his subject accordingly possesses, not merely a scientific and academic, but also a technical and commercial interest that should not be overlooked. This last chapter may more especially be recommended to the large number of mining engineers in this country who appear to think that the study of mineral deposits is one that they can venture to neglect as of no practical importance.

It is satisfactory to find that the wish expressed in the review of the first part of this book has been gratified, and that it is furnished with a good topographical as well as a general index, and it is a pleasure to be able to congratulate Dr. Beck on the production of a work of standard value upon the fascinating subject that he has done so much to advance. HENRY LOUIS.

ORGANIC CHEMISTRY.

Practical Organic Chemistry for Advanced Students. By Dr. Julius B. Cohen. Pp. xi + 284. (London: Macmillan and Co., Ltd., 1900.) Price 2*s.* 6*d.*

IN this enlarged edition Dr. Julius Cohen has increased greatly the value of the book as a manual for advanced students by adding chapters on organic analysis and the determination of the molecular weight. Under the latter heading we are glad to see he describes the preparation of the silver salts of organic acids and of the platinum salts of bases—two operations the description of which is frequently omitted from similar works. The appendix, which treats of the theory in the form of a note on each preparation, has also been enlarged. Our experience has been that students will not trouble to hunt theory in the limbo of an appendix, and the matter of these notes would have been more usefully incorporated in the preparations themselves. The explanations are necessarily condensed and frequently difficult to understand; for example (p. 193), "Aldehydes can only be obtained directly from the fatty acids by distilling the calcium salt with calcium formate; *but in no case by direct reduction, unless in the form of lactones.*"

The preparations are well and clearly described, and the apparently obvious is not ignored. Thus we read (p. 43), "A small balance with celluloid pans, for use on the bench, is indispensable." Such a balance is invariably used by German students in order to estimate their yields, but is a sufficiently rare object in an English laboratory.

Details of the preparation of ninety-seven substances are given, and consequently the book will be of great service, not only to the student, but also to the lecturer. Of the fifty-six substances usually prepared by the honour students at the Owens College, fifty-two are to be found in this book.

In a useful series of "Hints on the investigation of

organic substances" (p. 265) Dr. Cohen has made a most praiseworthy attempt to systematise the analysis of organic substances. This part of the book might advantageously have been expanded (if necessary at the expense of the appendix), when the futility of the closing hint[1] might have been avoided.

The old method for the preparation of diethyl malonate—the *pons asinorum* of the organic chemist—is still given, but a better yield is obtained by the method of Noyes (*Journal* of the American Chemical Society, 18, 1105, 1896); succinic acid melts at 185°, not 180°; the conversion of citraconic into mesaconic acid (p. 112) is due to Fittig, not to Jacobson; methyl oxalate (Prep. 24) is not indexed; and the preparation of kreatinine might advantageously have been omitted.

We must, however, congratulate Dr. Cohen on having produced the best elementary book, in the English language, on practical organic chemistry, and we have found that our students use the book with great confidence and are perfectly able to prepare any of the substances from the descriptions. The book, which is well printed and free from typographical errors, should rank with the similar works of Ludwig Gattermann in German, and of Dupont and Freundler in French.

[1] ["2, *Solids*.—A mixture of solids may be separated either by use of a suitable solvent which will dissolve one of the constituents more readily than the other, or by means of one of the reagents described above" p. 272)].

OUR BOOK SHELF.

Description of the Human Spines, showing Numerical Variation, in the Warren Museum of the Harvard Medical School. By T. Dwight, M.D., LL.D. (Memoirs of the Boston Society of Natural History). Vol. v. No. 7. Pp. 75. (Boston, U.S.A., 1901.)

THIS memoir is for the greater part a careful description, with elaborate tabulation and adequate illustration, of forty-five anomalous human back-bones which, with one exception, were obtained during many years spent by the author in the dissecting-room of the Harvard Medical School. In the introductory portion of the work the author discusses Rosenberg's methods and well-known theory of "concomitant variations," based on the appreciation of a tendency of the cervical and lumbar regions of the column to absorb into themselves the thoracic, with change progressive and retrogressive at the opposite ends of this. Accepting, without proof, the theory that the human ilium enters into relation with different vertebræ during development, the author passes on to the consideration of irregular segmentation, and a discussion of the views of Baur, Bateson and others on inter- and ex-calation, deferring the latter author's theory of "homœosis" for consideration in the body of the work. He finally denies the existence of a precise number of lumbar vertebræ, and finds refuge in Welcker's theory of the *vertebra fuleralis*. With this as a determining factor he largely deals, and the most interesting portion of his memoir is that in which he shows it to be the twenty-fourth vertebra in each of seven examples lacking one of the præsacral series. He classifies his specimens into classes, and clearly, systematically formulates the individual spines of each, and deals in some cases with correlated modification of the spinal nerves. Arguing that the "essential part of the office of the spine is to form the median support of the trunk," he deduces what he terms a "vitalistic conception," viz., that parts in corresponding situations exhibit a tendency to develop in a corresponding manner; and in finally discussing Rosenberg's view, he remarks that its success has been largely due to the fact that "it fitted in so perfectly with the doctrine of descent by gradual modifications," and gives as his opinion that, "unfortunately for science," it has "become too much the custom to make everything square with this."

The memoir as a whole is laborious, but accurate and systematic, and will be of great use to the working anthropotomist. There is appended a description of some incomplete specimens of interest in the author's collection, and we would remind him that among the quadrupedal mammals co-ossification of the atlas vertebra with the skull is at times found to be an effect of dislocation, and would recommend to his consideration the recent description by Broom of an Echidna's spine having eight cervical vertebræ, and his discovery that in some marsupials the fourth lumbar and anterior caudal vertebræ bear in the young state free ribs.

Where Black Rules White: A Journey across and about Hayti. By H. Prichard. Pp. 288. (Westminster: Archibald Constable and Co., Ltd., 1900.) 12s.

MR. PRICHARD visited Haïti in the year 1899 as a special correspondent of the *Daily Express*; and in the volume under notice we have his impressions and experiences described, with anecdotes and illustrations. He made a short trip into Santo Domingo, to which he devotes a chapter, but otherwise the book is concerned with the people, places and affairs of the part of the island governed by the Haïti Republic. Referring to the people of the Dominican State, Mr. Prichard remarks: "They are not nearly so likeable as the Haytian peasantry, and hospitality does not flourish in the same degree as on the western side of the border. On the other hand, the Government of San Domingo is less jealous of foreign influence. The Dominicans speak Spanish, and have preserved the purity of their language to a far greater degree than can be said of the Haytians, whose French has degenerated into a Creole patois so corrupt that it can with difficulty be understood by outsiders."

From a scientific point of view, the most important statements made relate to Voudou worship and sacrifice. The author says that the people of Haïti are practically under the control of Papalois or Voudou priests, otherwise Haïtian witch-doctors and medicine-men; and he brings charges against them of murders and human sacrifices which the Government of the Republic appears unable to prevent. As to the ceremonies connected with the worship of Voudou, he remarks: "There are said to be two sects of Vaudoux: one which sacrifices only fruits, white cocks and white goats to the serpent-god; the other, that sinister cult above referred to, whose lesser ceremonies call for the blood of a black goat, but whose advanced orgies cannot be fully carried out without the sacrifice of the goat without horns—the human child." Miss Kingsley touched upon this subject in her "West African Studies."

Mr. Prichard made a special point while in Haïti of obtaining information as to Voudou ceremonies and sacrifices, and in some cases was able to obtain direct knowledge. He gives an account of personal observations of some of the rites, which should be of interest to ethnologists.

Untersuchungen zur Blutgerinnung. By Dr. Ernst Schwalbe. Pp. 89. (Brunswick: Vieweg, 1900.)

DR. ERNST SCHWALBE herein summarises the previous researches on the chemistry and morphology of the coagulation of the blood, and adds some new observations of his own.

He has employed Reye's method of separating

fibrinogen from blood plasma by fractional precipitation with ammonium sulphate, and has studied the characters of the soluble fibrino-globulin of Hammarsten, which is present in solution after the fibrinogen solution has been clotted or coagulated by heat. He finds that fibrinogen is not filtered by pressure through a Chamberlain filter, while the other proteids of plasma, including fibrino-globulin, are driven through. He has also determined the heat coagulation temperature of fibrino-globulin.

Dr. Schwalbe has studied the clotting of freshly drawn blood, the blood being suspended in microscopical sections of elder-pith and protected from drying or contact with the cover glass. He concludes that blood platelets arise by the breaking down of red corpuscles, and that agents, such as calcium salts, which promote clotting do so by accelerating the breaking down of the red corpuscles. The original observations are scarcely of sufficient importance to warrant their publication in the form of a separate monograph.

A Manual of Elementary Science. A course of work in Physics, Chemistry and Astronomy, for Queen's scholarship candidates. By R. A. Gregory, F.R.A.S., and A. T. Simmons, B.Sc. Pp. viii+429. (London: Macmillan and Co., Ltd., 1901.) Price 3*s*. 6d.

OF the three parts into which this book is divided, those dealing with physics and chemistry are along familiar lines, but it may be stated that they are treated with the thoroughness and attention to practical details which the authors have accustomed us to expect. It is to the third part that teachers will turn with the greatest interest, for the reason that an effort is made to extend laboratory methods in the teaching of astronomy. Hitherto, with the possible exception of two American books, there has been no guide to this class of work suitable for elementary students who can only give a comparatively small amount of time to the subject. The practical exercises described comprise the illustration of astronomical phenomena by the use of simple apparatus; suggestions for observations of the heavenly bodies themselves, including measurements of altitude, &c., with home-made instruments; the graphical representation of the paths of the sun, moon and planets with the aid of an almanac; and easy numerical exercises. Those who have endeavoured to teach chiefly by the observation of the heavens will appreciate the provision made for instructive work when outdoor observation is not possible or convenient. The course laid down is certainly a step in the right direction, but it would be too much to say that it could not be improved. The use of the globes, for instance, might have been introduced with advantage.

It may be noted that Achernar, by some slip, has been wrongly included in the list of bright stars visible in England (p. 328).

The book throughout is admirably illustrated, many of the diagrams being original. A number of useful exercises are appended to each chapter.

The Mind of the Century. By various authors. Pp. 141. (London: T. Fisher Unwin, no date.) 2*s*.

THE essays in this volume are characteristic aspects of progress during the nineteenth century, seen from sixteen different points of view; they originally appeared in the *Daily Chronicle*, and it may perhaps be doubted whether any useful purpose is served by reprinting them. A glance at the lines of intellectual development may be sufficient for a daily newspaper, but it is scarcely accurate to describe a very general view as a representation of "The Mind of the Century." It will be sufficient to say that Prof. Tilden's article on chemistry occupies five pages, and he would probably be the first to disclaim any desire to have it regarded as more than a very slight sketch of a few lines of progress. Dr. H. J. Campbell writes on medicine, Mr. Edward Clodd on natural science (in which he includes astronomy), and Mr. W. A. Price on applied science, the whole of the articles on scientific subjects occupying thirty-three pages. To what extent the minds of men of science—both pure and applied—can be faithfully reflected within these limits we leave our readers to judge. The book has no index.

Morison's Chronicle of the Year's News of 1900. Compiled by G. Eyre-Todd. Pp. 446. (Glasgow: Morison Brothers, 1901.) 3*s*. 6*d*. net.

THIS is a diary of events and news of the year 1900, and it may be taken as a convenient index to the subjects which occupied public attention in the newspaper press during that year. It is in no sense a record of scientific thought and work, and the compiler has apparently made no attempt to form an accurate estimate of the relative standing of learned societies, or to apportion space according to the value of their proceedings.

In the index, under societies, we notice the Royal Society of Edinburgh (the reference being to a single meeting in 1900), but not the Royal Society of London; a meeting of the Scottish Meteorological Society is recorded, but none of the Royal Meteorological Society; the Society of Chemical Industry appears, but not the Chemical Society, or the Physical, or the Astronomical, or the Linnean, Zoological and many others. So far as science is concerned, therefore, a reader of the diary would prevent himself from being disappointed if he assumed that the volume took no account of the scientific news of 1900. We must, however, be charitable, for, after all, the news and events recorded in the volume are, to the general public, of more interest and value than many contributions to natural knowledge.

Imitation, or the Mimetic Force in Nature and Human Nature. By Richard Steel. Pp. xii+197. (London: Simpkin, Marshall and Co., Ltd., 1900.)

THE canon of affirmative reasoning, which may be said to form the text of this book, is expressed by the author as follows:—"That which is true of a thing is probably true of its like; the degree of probability depending upon the extent and thoroughness of the resemblance." This principle is applied to the reasoning employed in connection with such subjects as habit and instinct, psychology, physics and biology, and other branches of intellectual inquiry in the natural and spiritual worlds. It is the expression of the theory of imitation, which the author propounds "as a fundamental influence in human affairs and in the natural universe generally." Many general facts of natural history lend themselves easily to this idea, and use is made of them. How the author does this, and shows that even wave motion is "essentially mimetic or imitative," can be better read than described.

In Nature's Workshop. By Grant Allen. With 100 illustrations by Frederick Enock. Pp. 240. (London: George Newnes, Ltd., 1901.) Price 3*s*. 6*d*.

IN reading this book one cannot fail to notice a considerable resemblance between Mr. Grant Allen's manner of treating his subject and that adopted by the late Dr. Taylor in his "Sagacity and Morality of Plants." But while the latter work consisted only of examples taken from the vegetable kingdom, here the animal kingdom, and especially the insect world, receives a large share of attention. Thus there are chapters on "sextons and scavengers," dealing with burying beetles; "false pretences" and "masquerades and disguises," dealing with warning colours, mimicry and such matters; "animal and vegetable hedgehogs," dealing with spiny fishes, insects, cactuses, lizards and beetles; "plants that go to sleep." The book should prove delightful reading to young people and others who can take an interest in natural history treated in an unscientific and popular

way, and Mr. Enock's skill as an artist in portraying all sorts and conditions of animal and plant life greatly add to its charm.

Elementary Organic Analysis. By F. G. Benedict, Ph.D. Pp. vi+86. (Easton, Pa.: The Chemical Publishing Co., 1900.) Price 1 dollar.

DR. BENEDICT describes processes for the determination of carbon and hydrogen in organic analysis. His manual is distinguished by completeness of detail concerning the setting up and manipulation of the analytical apparatus, and the treatment necessary for various classes of compounds. The book should be of service in directing students how to carry out organic combustions satisfactorily.

Elevation and Stadic Tables. By A. P. Davis. Pp. 42. (New York: J. Wiley and Sons. London: Chapman and Hall, 1901.)

HYDRAULIC tables showing velocities for various channels and slopes are given in this volume, as well as tables "for obtaining differences of altitude for all angles and distances, horizontal distances in stadic work, &c., with all necessary corrections." The book has been prepared and published because there is a need for such a handy manual in the field work of surveying and in practical problems connected with canal construction. As such its usefulness is assured.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Recent "Blood Rains."

THE quantity of dust carried over to Europe by winds from the African Continent during the present month seems to have been unusually great, for traces of the "blood-rain" are said to have been noticed as far north as Hamburg and Schleswig-Holstein, while, in most cases, such phenomena are confined to the countries immediately bordering the Mediterranean. My colleague, Prof. A. W. Rücker, who has been staying at Taormina, in Sicily, has forwarded to me some very interesting observations which he has made on the subject. Writing on March 12, he says: "We have had a rather curious phenomenon here. The sirocco was blowing, and the hills were wrapt in mist, but the fog assumed a yellow hue, and the sun, which at times could be seen through it, was a bright blue. This was caused and accompanied by a copious fall of red dust. Some which I shook off my hat was quite dry, and on looking at it through a low-power lens all the granules seemed to be spherical, except a very few grains of what looked like quartz. Of course, the question was raised whether Etna was ejecting something which corresponded to the Krakatoa dust, but this was negatived by the fact that the Italian papers state that the dust fell also at Naples and Palermo in such quantity that the streets looked red and the people were frightened. I scraped some off a marble table which I send you."

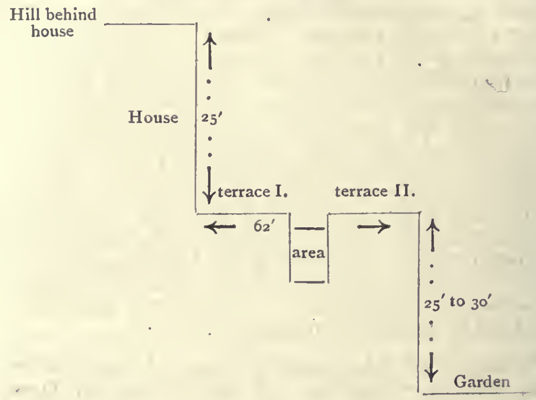
Under the microscope this dust is seen to be mainly composed of inorganic particles, chips of quartz in small quantities being mingled with minute plates of various micaceous and other minerals. There is also a fair admixture of frustules of freshwater diatomaceæ, entire and in fragments. The number and variety of these diatomaceæ does not appear to be so striking as in some of the celebrated cases described by Ehrenberg, the organisms from which were figured by him in his "Passat Staub und Blut Regen" (1847). There are, however, a very considerable number of species represented in these recent falls.

Vague statements have appeared in some of the newspapers as to the number of millions of tons of dust which, during the present month, have fallen over Italy. The data upon which these statements have been made have not been given, so that the following memorandum on the subject, drawn up by Prof. Rücker, cannot fail to be of interest to readers of NATURE.

Royal College of Science. J. W. JUDD.

March 20, 1901. *Taormina, Sicily.*

"At 7.30 this morning the sky was copper-coloured, and it was evident that another fall of dust was taking place. The sirocco had been blowing for two days, and it was raining slightly.



The general outline of the hotel is as shown. The two terraces are connected by a bridge. On the terraces were several rectangular marble tables, and it occurred to me that it might be interesting to find the amount of dust on some of them.

It is, of course, possible that the rain may have washed some of the dust off them, but I looked at the terrace when dry and saw no signs of a specially great aggregation of dust under the tables.

The aspect of the terrace is about S.W., so that the house did not shelter the tables, as the wind was blowing towards it; but, of course, eddies may have had an effect.

The sky ceased to be copper-coloured about 8 or 8.15, and I have no reason to suppose that any large quantity of dust fell while the experiments were being made.

Table I. Was on the western half of the inner terrace I., about 13' from the house. It measured $24\frac{1}{2}'' \times 46'' = 1127$ square inches. The mingled dust and water were scraped off with the edge of a sheet of paper into the cover of a biscuit box, then dried over a spiritine (alcohol) flame. The dust adhered rather strongly to the box, and had to be scraped off with a knife, which removed some shavings of the tinning.

Collection made at 9 a.m.

Table II. Further east, on terrace I., near a point where the level of the house fell to about 17'. Distance from house, 13'. Dimension, $22\frac{1}{4}'' \times 40\frac{1}{2}''$, or, say, 900 square inches. Collected as before but into two plates, one earthenware, and the other enamelled iron. The dust had to be scraped off, but I do not think the knife removed anything from the plates.

Collection made at 10.15 a.m.

Table III. This was the best experiment. The table was on the outer terrace, 58' from the house, and close to the edge of the terrace. Area, $24\frac{1}{4}'' \times 46\frac{1}{2}'' = 1127\cdot5$ square inches. The scrapers used were rags of clean muslin, which were afterwards washed in water to get as much dust as possible out of them, and the quantity so obtained (which was small) was added to the rest. The dust and water were put in a clean bottle and preserved. No drying was done in this case.

Collection made 10.45.

In the afternoon I borrowed a balance from a photographer. The smallest weight was a gram, but the balance would turn to less, and I made smaller weights by cutting a piece of stout paper to such a length that it weighed a gram, measured its length and cut off measured lengths from it. I weighed in both pans and found there was no important difference. The whole experiment was rough, but the amounts deposited on the two tables appear to have been so different that great accuracy in weighing is not important.

Table I. Weight of dust, 1·13 grams.
Area, 1127 square inches, or, say,
0·0010 gram per square inch.
Table II. Weight of dust, 1·54 grams.
Area, 900 square inches, or, say,
0·0017 gram per square inch.
Table III. Preserved wet, and therefore not weighed.

The difference between the results is too great to be accounted for by differences in care in scraping or errors of the weighings. It is either due to the fact that more dust had been carried off one table by the rain than off the other, or it shows that near the house the distribution was uneven. Still, the mean of the two gives an idea of the order of the density on the inner terrace, which was about 0·00135 gram per square inch, or, taking 25 mm. = 1 inch, 2·2 grams per square metre, or about $5\frac{1}{2}$ tons per square mile, though, of course, to argue as to the average fall over so large an area as a square mile is a big extrapolation.

Note upon a New Form of Spermatophore in an Earthworm.

IT is well known that the Oligochæta (like many other animals such as molluscs, insects, &c.) form spermatophores. Up to the present time two types of these spermatophores have been recognised in the Oligochæta. In the Lumbricidæ, *Criodrilus*, &c., they are compact cases, generally open at one end, and found invariably attached to the outside of the body in the neighbourhood of the reproductive orifices; they are sometimes even slightly imbedded in the skin. The other type of spermatophore characterises *Tubifex* and several allied genera, as well as the Eudrilid earthworm, *Polytoreutus*. These are long thin motile bodies. They are found only in the spermathecæ of those Annelids which they characterise. I have lately studied the structure of a third variety of spermatophore which I found in the spermathecal sac of another Eudrilid genus, *Stuhlmannia*. This worm is long and slender, not measuring more than 2 mm. in diameter. The spermathecal sac in which the spermatophores are found is about 7 or 8 mm. long. I never found more than two of the spermatophores in a sac; they measure some 3 mm. in length. The shape is peculiar. There is a "head" very similar to that of the spermatophore of *Tubifex*, a long "beak," open at the extremity, is followed by a circumferential swelling, which is again succeeded by a narrow neck; this in its turn gradually widens until at the middle the spermatophore is large and plump. The interior was a mass of separate spermatozoa entirely uncompacted together. The site of the formation of the spermatophores has been much disputed. It seems to be clear, from the investigations of Mr. Lankester, that in *Tubifex* they are at least moulded in the spermatheca, since the collar of the head of the spermatophore not only corresponded in form with certain foldings of the spermathecal wall, but was actually observed lying *in situ*. As to the origin of the material, Mr. Lankester and Prof. Vejdovsky were disposed to trace it, partly at least, to the "cement gland" of the male efferent apparatus. I find in *Stuhlmannia* that the moulding of the head of the spermatophore must be accomplished in the spermathecal sac, since I also observed a spermatophore lying *in situ* with its convexities fitting into corresponding concavities of the walls of that sac. Further, the large size of the spermatophore necessitates the hypothesis that the whole of it is moulded in the sac, since it could not possibly be contained—even with the greatest stretching—in the spermiducal gland. As to the origin of the material of the case, I hold it to be proved that part comes from the spermiducal gland and that the rest is, in all probability, a result of the breaking down of the abundant cells which line the spermathecal sac. I may add that no spermatozoa protrude through the case. This spermatophore of *Stuhlmannia* is evidently somewhat intermediate in its characters between the two types already known.

FRANK E. BEDDARD.

Graphic Solutions of the Cubics and the Quartics.

THE note by Prof. G. B. Mathews, F.R.S., published in NATURE of November 16, 1899, has encouraged me to write the following, which may be also of some interest. I have considered not only the quartics, but also the cubics. For the quartics, the methods in this letter will be simpler than those of Prof. Mathews. We require to have a sheet of squared paper on which the curve $y=x^3$ for the cubic and the curve $y=x^2+x^4$ for the quartic have been printed.

I. For the cubic, take the curve $y=x^3$ and a straight line the equation of which is $\frac{x}{a}+\frac{y}{1}=1$. Then the abscissæ of the intersections of the curve and the straight line are the real roots of $x^3 + \quad - 1=0$. Now the general cubic is at once reducible to the form $z^3+pz+q=0$, and if we put $z=-x\sqrt[3]{q}$, this becomes $x^3+\frac{p}{q^{\frac{2}{3}}}x-1=0$. This is identical with the former if $a=\frac{q^{\frac{2}{3}}}{p}$; so we can calculate a very easily, then read off the real values of x, and finally take $z=-x\sqrt[3]{q}$.

II. For the quartic, take the curve $y=x^2+x^4$ and a straight line the equation of which is $\frac{x}{a}+\frac{y}{b}=1$. Then the abscissæ of the intersections of the curve and the straight line are the real roots of $x^4+x^2+\frac{b}{a}x-b=0$. Now the general quartic is at once reducible to the form $z^4+pz^2+qz+r=0$, and if we put $z=x\sqrt{p}$, this becomes $x^4+x^2+\frac{q}{p^{\frac{3}{2}}}x+\frac{r}{p^2}=0$. This is identical with the former if $a=-\frac{r}{q\sqrt{p}}$, $b=-\frac{r}{p^2}$; so we can calculate a and b very easily, then read off the real values of x, and finally take $z=x\sqrt{p}$.

For the quartic, we can take also the parabola $y=x^2$ and a circle $(x-a)^2+y^2=\rho^2$.

T. HAYASHI.

Matsuyama Chūgakkō, Iyo, Japan, December 28, 1900.

"The Principles of Magnetism and Electricity."

THERE are two points occurring in the review (p. 434) of "The Principles of Magnetism and Electricity" in which the author appears to me to be correct, though the examples are given as instancing errors into which he has fallen. The reviewer states, "The author measures magnetic force in *dynes* and difference of potential in *ergs*," thereby apparently implying that this is incorrect. Surely these are usual units for expressing these quantities. Again, the author is taken to task for stating that in the case of a dynamo or motor armature, "owing to the self-induction of each section, a certain amount of energy is used twice in each revolution to establish the current in it. *This energy is lost* so far as the external circuit or the effective output of the machine is concerned." Whilst with a dynamo running sparklessly with copper brushes this is only partially true, the difficulty of obtaining the return of the energy thus absorbed is in practice so great that we see on a very large proportion of machines that carbon brushes are used, the object of which is to enable this energy to be wasted without an actual spark, and it is well known that machines with carbon brushes thus working have a higher rise of temperature from the waste of power than when true electrodynamic commutation takes place. Actual measurements of power absorbed have also shown a waste of power from this cause sometimes exceeding 5 per cent. of the output of the machine.

London, March 12. LLEWELYN B. ATKINSON.

THROUGH the courtesy of the Editor I am able to reply to the letter of Mr. Llewelyn B. Atkinson, in which he challenges two of my criticisms in the review of "The Principles of Magnetism and Electricity," by Mr. P. L. Gray. Mr. Atkinson states that I "apparently imply" that measuring magnetic force in *dynes*, and difference of potential in *ergs*, is incorrect. To prevent any misconception, I now wish to state quite definitely that I regard the above method of measurement as hopelessly and absolutely wrong. If it be correct, then magnetic force is a quantity whose dimensions are identical with those of dynamical force, and difference of potential a quantity of the dimensions of energy. If Mr. Atkinson is satisfied with these conclusions, and is prepared to uphold them, I have no further remarks to offer on the subject. I may, however, point out that measuring difference of potential in ergs is about as logical a proceeding as measuring difference of (gravitational) level in ft.-lbs. Some eccentric people might, no doubt, be found to uphold this latter proceeding. But a falsehood does not become a truth merely because a number of people give their unreasoning assent to it.

With regard to the second criticism, that relating to the process of commutation in a dynamo, I still maintain that the statement in Mr. P. L. Gray's book is misleading and incorrect in its generality, and Mr. Atkinson practically admits as much in his letter. Nothing is said by Mr. Gray as to the particular statement in question being intended to apply to carbon brushes under certain conditions of use. It is a general statement, made without any qualifications, and as such is incorrect.

THE REVIEWER.

THE LAND WORK OF THE BELGIAN ANTARCTIC EXPEDITION.

At the present moment the Antarctic problem is mainly that of the forthcoming expeditions, and during their preparation every fact bearing upon the conditions, physical and official, in which the scientific staffs will have to work has a special interest. So far the Belgian expedition has yielded most information of a useful kind, and the two latest papers of its enthusiastic geologist, M. Henryk Arçtowski, are of more than usual value.[1] The general account of the expedition contains nothing that will be new to our readers. M. Arçtowski concludes it by the observation that while the scientific results have been varied and satisfactory, the chief outcome is that the great public has been acquainted with the paucity of our knowledge of the Antarctic area, and shown how trifling is the work accomplished compared with that which remains to be done.

The paper in the *Geographical Journal* is the most detailed and valuable description of land on the confines of the Antarctic region that has ever been published. It records, in the form of a narrative from day to day, the exploration of Belgica Strait, the new channel discovered by the expedition, separating the Palmer Archipelago from the mass of Graham Land with which those islands were formerly supposed to be continuous.

The twenty landings which the importunity of M. Arçtowski induced the reluctant commander to permit are described in detail; but, as none of the new names given by the expedition are employed, and practically no other names exist in that region, it is impossible to follow the description without reference to the sketch map on which the landings are marked. This is accordingly reproduced as Fig. 1.

The opportunities of landing were numerous, but the time allowed on shore was usually absurdly inadequate to the importance of the work of surveying and geological investigation. In the only case where a week was spent on shore practically nothing was done because of the unnecessarily heavy equipment insisted on by the commander—a sailor of no scientific qualifications, and apparently devoid of sympathy with the more important objects of the expedition. Still, it must be remembered that but for de Gerlache's burning ambition to reach a high southern latitude (an ambition which was not gratified) the expedition would never have been dispatched, and no scientific work of any kind would have been done. The following paragraphs are a much-abridged summary of M. Arçtowski's narrative.

At 7 p.m. on January 23, 1898, having passed the South Shetlands, the *Belgica* was close to a headland, which probably was Cape Cockburn, but as she went on the charts became valueless. What was seen corresponded to nothing that they represented, and Lecointe proceeded to construct a fresh chart from his own surveys. At 10.30 p.m. the first landing was made on an island in Hughes Bay (see I. on map, Fig. 1). A considerable part of the island was uncovered. The upper part was like a lava-flow of prismatic structure. Lower down the rock was completely cracked, and seemed to decompose in large superimposed blocks with straight surfaces. It was an eruptive rock of great density, very hard and brittle, and ringing on a blow with the hammer. It was not basaltic, but of granitic structure and very fine-grained; its colour was a very deep green, and M. Arçtowski thought that he saw small crystals of hornblende; if so, the rock would be a diorite.

On January 24 the second landing was made (II. on map, Fig. 1) on a small narrow island, no more than 100 feet high and almost free from snow; it appeared to be surrounded by a close colonnade, on account of the regular vertical cracks in the rock, which were doubtless produced by extreme cold. The surface was frequently mammilated and worn smooth by the ice. Here, M. Arçtowski says, "A little sandy clay mixed with guano was found in small pockets between the rocks, and while examining this I had the pleasure of discovering the first Antarctic insect, almost microscopic in its dimensions." The general result of that day's nautical work had been the discovery of an elevated land where Friederichsen's map bore the inscription, "No land in sight (Larsen)." Towards the east and south an uninterrupted coast-line stretched as far as the eye could

FIG. 1.—The track of the Belgian Antarctic Expedition in Belgica Strait. From the *Geographical Journal.*

reach, but in the south-west a large strait opened into Hughes Bay, and this it was necessary to explore. The quantity of snow on the land was found to be formidable. The westerly and northerly winds coming from the ocean doubtless brought great falls of snow, and this was always accumulating, mountains of ice were reared on the top of the mountains of rock. So far as could be judged from the ship, the ice was nowhere uncovered, but thick snow seemed to lie on the glaciers down to the very edge of the sea.

About midnight a landing was made in a little bay (III. on map, Fig. 1), where a ground moraine, or something closely resembling one, was found. There was water behind it and then a cliff of ice, the end of a great glacier which covered the whole slope of the mountain. Although it was growing very dark and the specimens were collected hurriedly, more than ten different varieties of rocks were obtained, none, however, of sedimentary formation.

The next landing was for three hours, on the 25th, in lat. 64° 6′ 24″ S., long. 61° 59′ 30″ W., on the promontory of an island (IV. on map, Fig. 1), and it was not without difficulty that all the delicate instruments were got ashore on the steep rocks. "Cook and I," says M. Arçtowski, "made use of Canadian snow-shoes to visit the higher part of the island, and found them a great aid in crossing the snowy slopes, which were usually gentle, though there were dangerous crevasses in places. A thick mantle of snow stretched to the crest of the promontory and stopped abruptly, the further side being perpendicular. . . . It was a region quite alpine in its character, but completely buried, in glaciers. The snow-fields rose towards the interior forming a veritable ice-cap, terminating in a perfectly continuous sky-line. . . . Lower down the relief of the land could be divined beneath its robe of snow, and here and there a bare peak pierced the covering. Nothing like an exposed chain of mountains was to be detected, although near the sea a coast range could be made out, its sides cut by valleys through which glaciers of various sizes made their way. Along the shore some of the promontories were bare, but on the lower ground the ends of the glaciers were covered by a field of snow, and were for the most part confluent, forming a plateau of ice which gave origin to icebergs. That valleys exist, though they do not show on the surface, is clear from the differences in the size and appearance of the glaciers. The largest are of gentle slope, the smaller steep and broken by numerous crevasses. Some of the glaciers suspended from the cliffs were of extraordinary dimensions. Thus by the appearance of the surface of the ice, without any other evidence, one could see that the configuration of the buried land was complicated, and underneath each glacier there must be a great excavated valley, along the bed of which the ice glides downward. The existence of valleys is very interesting, for it points to a time when there was no ice, but dry land being eroded by the running water of rivers. On the other hand, the thought of these buried valleys brought to my mind the channels of Tierra del Fuego as they must have appeared in the glacial period, when the end of the Andean chain lay under just such an ice-sheet."

In the afternoon of Wednesday, January 26, Cook, Amundsen and Arçtowski landed on Two Hummocks Island (VI. on map, Fig. 1), which was narrow and entirely covered with a thick mantle of snow, giving it a convex appearance. Two pyramidal mountains projected like nunataks, contrasting with the general smooth outline. The party landed on the north coast in the hope of being able to climb one of the mountains, and found that the shore was formed by a cliff of ice, with only a few promontories of bare rock. The ice was not found to be actually immersed in the water at any point; a very narrow strip of bare rock always separated it from the sea. A little snow rested even on the *roches moutonnées*, which bordered the shore, either awash or rarely rising so much as a yard or two above the surface, and the sea-leopards were sleeping upon them very tranquilly. The rock of the island was a grey granite, with thick and very regular veins of a dark and compact green rock, and also smaller red veins. There were some erratics, which might have been carried by floating ice.

At 2 p.m. on the 28th an island was visited which showed an appearance of stratification (VIII. on map, Fig. 1), but the whole surface was found to be a smoothly glaciated rock of eruptive origin, traversed by grey compact veins twenty feet thick.

On Saturday, January 29, the weather was calm; the fog had cleared away and revealed a marvellous scene. On every side the thick white covering descended to the sea, and only the most abrupt slopes were free from snow; perpendicular cliffs and steep hillsides were characteristic of all these coasts. A cliff which bordered a submerged valley where an immense glacier debouched showed an appearance of vertical stratification, but the ninth landing sufficed to prove that this appearance was due merely to cracks in the rock, as in all previous cases. This may possibly be an effect of extreme cold, for the *roches moutonnées*, which are preserved from rapid changes of temperature by a covering of snow during most of the year, do not exhibit such cracks, or only to a slight extent.

The only attempt at a land journey must be described in the author's own words. It commenced on Sunday, January 30. "The commandant decided to accompany the land-party, . . . but the preparations which had to be made were too elaborate, and the projected excursion was doomed to failure before it set out. In order to succeed, it would have been necessary to carry all the absolute necessaries on our backs and make a great and sustained effort, being prepared, if the route was bad, to return and choose a better way. . . . We took with us two sledges of Nansen's pattern, sleeping bags, a silk shelter tent, a little aluminium stove, such as was used by Jackson, Norwegian *ski*, Canadian snow-shoes, ice-axes, a 40-foot rope of raw silk, provisions for a fortnight, even changes of underclothing, and all the instruments after that. Certainly far too much baggage. . . . We landed on a little promontory at the head of a fine bay, where a large glacier entered the sea and the snow lay down to the water's edge (X. on map, Fig. 2[1]). There was no difficulty in getting ashore, but the sledges were horribly heavy. . . . At a height between 400 and 600 feet we had to cross several crevasses, which were narrow and spanned by snow-bridges solid enough to allow our loads to pass without difficulty. Higher up a great snow-field stretched before us, whence we could look down upon the glacier which cascaded towards the bay. . . . At 2.30 p.m. during lunch I placed the black-bulb thermometers on the snow, and, although the sun was slightly veiled, they showed readings of 102°·6 and 86° Fahr., while the temperature of the air, measured by a sling thermometer, was only 34°·2. The strength of the solar radiation made us all feel very warm. We enjoyed an extensive view towards the south, and saw the high mountains on the opposite side of the strait diminishing gradually in height towards the east; the direction of the chain seemed to be north-east and south-west. . . . At 7 p.m. we were still mounting upwards, the weather being remarkably good, and the view of Graham Land grew finer and finer. The relief of that land, although excessively varied, is singularly softened by the glaciers and the accumulated snow, so that it can only be because the valleys, hollowed by the running water of some former epoch, are so deep that a few crests and very abrupt slopes remain bare. At the height of 1600 feet

[1] Fig. 1. in this article.

we were stopped by a crevasse more than thirty feet wide, which we could not cross, and other crevasses appeared beyond it, the whole glacier having a terraced structure. . . . All Tuesday we were dragging our loads uselessly towards a hill in the west, but in that direction also we were stopped by numerous crevasses. . . . Again we had to retrace our steps to the ice-plain to pass the night, and there we left our camp for the two following days, seeing that it was impossible to reach any high summit. . . . From the summit of the more distant nunatak, Cook and I had a good view of the *mer de glace* in which the large glacier terminated at the head of the bay where we landed. Although the broken fragments could not give rise to icebergs as they entered the water, it seemed quite possible that in winter, when the bay is frozen, enough ice might accumulate to form one or more bergs. In any case, it appeared certain to me that the bottom of this great valley extended below the level of the sea; and I was also led to believe, judging from the distances which separated the nunataks and the angle of slope of the walls, that the same held good for the valley in which we camped. We found some lichens and mosses on the nunataks."

On Sunday, February 6, the party got on board the *Belgica*, and steered towards the east, in order to continue the survey of the coast of Graham Land. The air-temperature was high all that day, with a maximum of 45° F. At night it rained, at times very heavily, and it must have produced a great effect upon the snow-fields, a much greater effect, probably, than a day of strong sunshine.

The party succeeded in landing on February 7 at the base of a granitic cliff, near which, upon a little promontory, a metamorphic schist was discovered in contact with the granite (XIII. on map, Fig. 1). The direction of the strata was north-west and south-east, and their dip towards the north was about 45°; a very friable schist alternated with a dark quartzite, and dark green strata of a highly metamorphosed rock.

The fourteenth landing (XIV. on map, Fig. 1) was on a large island. M. Arçtowski thus describes it: "I saw a channel which separates it in the south-west from another land; and to the north-west the sea-horizon was unbroken—it was the Pacific Ocean. I saw this confirmation of my theories[1] with much pleasure; there was no doubt that we were on the west coast of the continental land symmetrically placed with regard to the Southern Andes. There is no passage to the east, and the Biscoe Islands form a parallel chain belonging to the mountain system of Graham Land. . . . We remained some time on the strip of bare rock which was exposed between the field of névé and the sea. It was the same black granitoid rock traversed by thick veins and narrow threads of quartz; and there was a great variety of erratic blocks, including specimens of basalt, breccia, several blocks of conglomerate, and some fragments of quartzite. A cave was found in the large-grained porous ice-wall, along the uncovered bed of which a little stream flowed, the first glacier stream I had seen. It came from the direction of a nunatak, and consequently could not have pursued its course from a long distance under the ice; in its bed there were rolled pebbles of eruptive rocks."

On Wednesday, February 9, at 7.30 a.m., the fifteenth landing was made (XV. on map, Fig. 1). The whole coast appeared like one great *roche moutonnée* entirely free from snow, everywhere smoothly polished and scored with sharp grooves, often very deep, running in all directions and crossing each other. The larger were vacant, but others were filled with thin leaves of rock, and some with compact grey veins giving the rock a schistose appearance. The surface of the granite was strewn with splinters split off by the effects of radiation, usually from one-third to two-thirds of an inch thick, and about a foot in diameter. There were no erratic blocks. The rocks were bare up to a height of about 150 feet, but from this level snow uniformly covered the island and gave rise to a trickle of water, forming cascades, under which an abundant vegetation of mosses and algæ had accumulated. A few tufts of moss were found here and there among the stones. The sun shone strongly, and the bare rock grew quite warm. At 8 a.m. on the *Belgica*, when the air temperature was 41° F., the black-bulb thermometer in the sun read 87°·8, hence the splintering of the surface of the rocks could easily be understood. At 10.30 the *Belgica* passed the cape at the south end of the mountainous island, and the recording thermometer fell, while the hygrometer rose sharply as the influence of the ocean made itself felt; and in the distance great icebergs could be seen in the open Pacific. At 11 o'clock the sixteenth landing was made on one of a group of twelve small low islands (XVI. on map, Fig. 1). Lecointe landed for the noon observation of the sun, making use, as before, of an artificial horizon; Arçtowski, Racovitza, Cook and Danco accompanied him. The whole islet was covered with moist snow almost to the water's edge; a remarkable difference in the height of the snow-line being observable in the short distance separating the fifteenth and sixteenth landings. All the islets of the neighbourhood had the same appearance, like great whale-backs rising from the sea. The polished rock extended to just below the surface of the water, and there were also several glaciated rocks scarcely emergent. The whole group seems to form a plateau which has been profoundly glaciated, and of which only the higher portions now appear; but this plateau has nothing, in M. Arçtowski's opinion, in common with the continental shelf, the whole of the district presenting clear evidence of being a submerged region. From another point of view, these islands are by no means to be considered as the stumps of mountains worn down by marine erosion; they afford evidence of a great extension of glaciers in some bygone period. The whole of Belgica Strait had probably at one time been filled by a great glacier which flowed to the Pacific. The cutting off of the summits of these islands may be its work.

At noon on February 10 the eighteenth landing was made, almost opposite the seventeenth, on the other side of the large channel (XVIII. on map, Fig. 1). It was at the base of a pyramidal mountain of red rock, very different in appearance from the surrounding scenery. A great band of red granite seemed to traverse the region from north-north-west to south-south-east. The interesting feature of this landing was the discovery of a moraine, at least 70 feet in height, which was set against the mountain-side along part of the beach in the direction of the channel. The rock itself was highly glaciated to just below the level of the water. Here we must once again give the author's own words: "The commandant showed himself very obliging, but with a little goodwill we could have landed in many other places and collected much more geological material than we did. For this eighteenth landing he conducted me himself, but for ten minutes only. A few strokes of the oars brought us to the beach, amid cries of "Hurry up, Arçtowski!" I gave a hammer to Tellefsen, with orders to chip here and there down by the shore, while I hurriedly climbed the moraine, picking up specimens as I ran, took the direction with my compass, glanced to the left and right, and hurried down again full speed to get a look at the rock *in situ*; meanwhile Cook had taken a photograph of the place from the ship—and that is the way geological surveys had to be carried out in the Antarctic."

At ten a.m. on February 11 the twentieth and last landing was made on the Pacific slope of the Needles,

[1] *Bull. Soc. Géol. France*, 1895, p. 590

which form the northern cape of Graham Land (XX. on map, Fig. 1. and view Fig. 2). In places the beach was quite free from snow, elsewhere there were small glaciers clinging to the slopes of the mountain and terminating seawards in cliffs of ice. The steep rocky slopes above were absolutely bare up to a height of 700 or 1000 feet, and beyond that rose fields of névé. Two of the party climbed a little ridge running at right-angles to the range of the Needles. An inclined plane of snow, interrupted here and there in the upper part by transverse crevasses easy to cross, led them to the rocky wall, which there was no difficulty in climbing, thanks to the numerous joints widened by weathering so as to cut up the face of the rock into superimposed blocks, and thanks also to the narrow chimneys down which the débris of the rock slipped. It is remarkable that these rocks remained quite bare at an elevation far above the snow-line. It is not sufficiently accounted for by the steepness of the slope, though that would make it possible for only a small quantity of snow to accumulate; but the dark walls were so strongly heated by the sun that the snow was actually melted. In making the ascent it was found that the low cloud, characteristic of these regions, was very thin and level on both the lower and upper surfaces, the belt of mist having been passed through between the altitudes of 150 and 300 feet, and above that there was an absolutely clear sky and dazzling sunshine, while the cloud extended as a smooth grey sea underneath. If such a condition often occurs, it is easy to see how the higher rocks become free of snow in summer, while those near sea-level remain covered.

After this landing the *Belgica* entered the Pacific, turned southwards into the ice-pack, and for a year drifted hither and thither, fast in the ice out of sight of land.

FIG. 2.—The Needles seen from the Pacific. From the *Geographical Journal*.

THE INTERNATIONAL ASSOCIATION OF ACADEMIES.

AN account by M. Gaston Darboux, permanent secretary of the Paris Academy of Sciences, of the inception and first meeting at Wiesbaden of this International Association, was given in NATURE for July 12, 1900. To the January number of the *Journal des Savants* M. Darboux contributes a further article on the same subject, in which, after again sketching the events which led to the rise of the Association, he gives an account of the Paris meeting and the arrangements for future work.

In this interesting article it is explained that the Royal Society and the Paris Academy took the initiative in the formation of this important Association, the advantages of which were pointed out by Lord Lister, as president of the Royal Society, in a letter dated November 17, 1898, addressed to the president of the Academy of Sciences of Paris. Among the questions of the first importance is that of the Catalogue of Scientific Papers, already commenced single-handed by the Royal Society. To carry this out completely it has been estimated that in the domain of the positive sciences alone the annual catalogue should comprise seventeen volumes and about two hundred thousand entries, a task evidently capable of being successfully accomplished only by combined international effort.

The academies and societies represented at the Wiesbaden conference decided to found an International Union of the principal scientific bodies of the whole world under the name of the "International Association of Academies"; the members of this Association being as follows:—

(1) The Royal Prussian Academy of Sciences, at Berlin.
(2) The Royal Society of Sciences, at Göttingen.
(3) The Royal Saxon Society of Sciences, at Leipzig.
(4) The Royal Society, at London.
(5) The Royal Bavarian Academy of Sciences, at Munich.
(6) The Academy of Sciences, at Paris.
(7) The Imperial Academy of Sciences, at St. Petersburg.
(8) The Royal Academy, at Rome.
(9) The Imperial Academy of Sciences, at Vienna.
(10) The National Academy of Sciences, at Washington.

The following academies were also invited to take part:—

(1) The Royal Academy of Sciences, at Amsterdam.
(2) The Royal Belgian Academy of Sciences, Literature and the Fine Arts, at Brussels.
(3) The Hungarian Academy of Sciences, at Budapest.
(4) The Society of Sciences, at Christiania.
(5) The Royal Society of Sciences, at Copenhagen.
(6) The Royal Academy of History, at Madrid.
(7) The Academy of Inscriptions and Literature, at Paris.
(8) The Academy of Moral and Political Sciences, at Stockholm.

Rules were also formulated regulating the admission of new academies, the constitution of the council and committee, the holding of general meetings every three years, and the mode of government during the intervals between the general meetings.

It was decided that the first reunion of the International Association should be held in Paris in July 1900. At this conference, besides formal business dealing with questions of constitution, three propositions brought forward by constituent academies were considered. The Royal Society drew attention to the desirability of connecting the measurements of Struve upon the arc of meridian 30° E. with those of Gill on the same meridian in South Africa; the Academy of Berlin raised the question of the best means of facilitating access to manuscripts and other documents; and on the proposi-

tion of the Paris Academy it was decided to assume control of the committee of physiology, having for its object the standardisation of the self-recording instruments used in physiology and increased uniformity in the methods used in that science.

M. Darboux concludes his article by mentioning a matter which proves at least the interest excited by the formation of the International Association of Academies, namely, that intended donations have already been announced. At the suggestion of M. Diels, it has been decided that any one having expressed the desire to give to the Association the means to develop its action could make the donation, with special instructions, to any of the academies taking part in it. Other less determinate projects will come before the general meeting. One, from the Academy of Munich, has reference to the publication of a "Corpus des actes et diplômes grecs du moyen âge et des temps postérieurs."

Another, suggested by the Academies of Leipzig, Munich and Vienna, is the publication of a "Real-Encyclopædie des Islam."

The committee meeting at Paris had finally to fix the date of the next meeting, the first general meeting. It is to be supposed that some, at least, of the proposals here made known demand careful consideration; hence, to leave the academies which have presented them time to give them a precise and definite form, Tuesday, April 16, which follows Easter Tuesday, 1901, has been fixed as the date of the next general meeting of the Association at Paris.

The various discussions and proposals mentioned are, without doubt, of unequal importance; they have at least the merit of being very varied and of putting in evidence the diversity of the services that may be rendered by the International Association of Academies.

The Association has been received with favour wherever science is cultivated. "Already," remarks M. Darboux, "we look to it for many works which it alone will be capable of realising. It may be recalled that the agreement between scientific men in the field of theoretical research often precedes a good understanding between peoples in the field of practice and business. There is a feeling that a new organism has been created, which should ultimately be called upon to exert a great and beneficent influence. It is important that the constituent academies should justify this feeling and forward the working of the Association by submitting carefully thought out proposals. It is important, also, that all those who expect much from the Association should bear in mind that it has time before it; that, by their very nature, academies are bodies which move with a certain slowness; and that time ought to be given to the new Association to create little by little the means by which it may be able to realise all the hopes to which it has given rise."

PROF. C. F. LÜTKEN.

CHRISTIAN FREDERIK LÜTKEN was born on October 7, 1837, at Sorö, a small town in Zealand, which at that time possessed an academy where his father was professor of philosophy. When quite a young man, even before his student days, his interest in the natural sciences was awakened, and after his examinations were completed he devoted himself heart and soul to zoology. In 1848 his studies were interrupted by the war between Germany and Denmark, in which he enlisted and served as a lieutenant. In 1852 he left the army and obtained his master's degree with distinction, almost immediately after which he was appointed assistant to Prof. Steenstrup, at Copenhagen, whose pupil he had been in his early days at Sorö. Thus began a connection with the zoological museum of the University which lasted for 47 years, terminating only when illness enforced his resignation.

His career was marked by constant devotion to the collections under his charge, and by the publication of a long series of scientific memoirs, published chiefly in the *Transactions* (Skrifter) and *Proceedings* (Oversigt over de Forhandlinger) of the Royal Danish Academy of Sciences, and the *Communications* (Videnskabeliger Meddelelser) of the Natural History Society of Copenhagen. His studies were always intimately connected with his work in the museum, and hence systematic zoology and geographical distribution and, to some extent also, palæontology constituted the main subject of his writings. Almost every one of the larger divisions of the animal kingdom owes something to Lütken's industry, but during his earlier years he concentrated his attention principally on the echinoderms, and later on ichthyology. Under the title "Dyreriget" he published a small text-book of zoology, a work which would have attracted considerable attention had it been in a language more generally understood. It is still the authorised text-book in most of the educational establishments in Denmark. Amongst his scientific writings special attention may be called to three papers on the echinodermata of Greenland and on the geographical and the bathymetrical distribution of northern echinodermata, which constituted the thesis for his doctor's degree; to a memoir entitled "Spolia Atlantica," which gives a large series of important observations on the young stages of many species of fish, and to a communication on *Himantolophus reinhardti*, a deep-sea lophioid fish, in which he first called attention to the probability that the attracting tentacles in these forms are phosphorescent.

On the death of Prof. Reinhardt, in 1883, he was appointed "inspector" of the department of vertebrates, and in 1885 he succeeded Steenstrup as professor of zoology and director of the museum. As a professor he was by no means the conventional pedagogue, and his pupils obtained from his lectures a clear and striking picture of the animal kingdom. Physical weakness, however, gradually grew upon him, and in his later years it was only with difficulty that he accomplished any teaching at all, and his auditors were frequently anxious lest he should be unable to complete his lecture, so feeble and distressing was his appearance. In 1897 he resigned the chair, and for the last year of his life was a victim of paralysis, which completely disabled him. He died on February 6, 1901, leaving behind him a record of valuable services to the University and to the science which he loved, and the memory of an intellectual and genial personality in the minds and hearts of all who had the privilege of his personal acquaintance. W. E. H.

NOTES.

Reference was made in our issue for February 28 to the retirement of Sir A. Geikie from the office of director-general of the Geological Survey, and to the appointment of Mr. Teall as successor. Mr. Teall takes the title of director of the Geological Survey and Museum, and the further changes in the staff (which date from April 1) are as follows: Mr. H. B. Woodward to be assistant director (for England and Wales), and Mr. John Horne to be assistant director (for Scotland); Mr. C. Fox Strangways, Mr. Clement Reid and Mr. Aubrey Strahan to be district geologists for England and Wales; Mr. B. N. Peach and Mr. W. Gunn to be district geologists for Scotland; and Mr. G. W. Lamplugh to be district geologist for Ireland.

Sir Archibald Geikie will be entertained at a complimentary dinner on May 1, as a mark of recognition of his services to geology, and in commemoration of his recent retirement from the position of director-general of the Geological Survey and

director of the Museum of Practical Geology. The dinner will be given at the Victoria Hall, Criterion Restaurant, and the chair will be taken by Lord Avebury. The committee includes many distinguished and representative men of science, among them being Lord Kelvin, Lord Lister, Sir William Huggins, K.C.B., Sir Norman Lockyer, K.C.B., Sir John Murray, K.C.B., Sir Michael Foster, K.C.B., Sir William de W. Abney, K.C.B., Sir William Turner, K.C.B., Sir Henry Howorth, K.C.I.E., and Profs. Judd, Bonney, Le Neve Foster, McKenny Hughes, J. Geikie, Ray Lankester and Lapworth, as well as a number of other Fellows of the Royal Society. Tickets for the dinner can be obtained from the honorary secretary of the committee, Mr. F. W. Rudler, 28, Jermyn Street, S.W.

PROF. HUMBERT has been elected a member of the section of geometry of the Paris Academy of Sciences, in succession to the late M. Hermite.

THE summer meeting of the Anatomical Society of Great Britain and Ireland will be held in the Yorkshire College, Leeds, on Friday and Saturday, July 5 and 6.

WE learn from *Science* that Dr. Robert Bell has been appointed director of the Geological Survey of Canada, in succession to the late Dr. G. M. Dawson; and that Dr. S. W. Stratton has been appointed director of the newly-established U.S. National Bureau of Standards, by Mr. McKinley.

THE Easter excursion of the Geologists' Association will be to Kingsbridge, Salcombe and district, under the direction of Mr. W. A. E. Ussher and Mr. A. R. Hunt. The members taking part in the excursion will leave Paddington on the morning of Thursday, April 4, and return on the following Tuesday evening.

IT is announced from Berlin that the German Emperor has abandoned his original intention of opening in person the forthcoming fifth International Congress of Zoology, which is to be held in the German capital on August 12-16, and that, in consequence of a special desire on the part of the Empress, the German Crown Prince has undertaken to perform this task.

MR. VAUGHAN CORNISH has returned from an expedition in search of snow-waves in Quebec, Manitoba, the North-West Territories and British Columbia. These waves were found to be well developed on frozen rivers and lakes and on the open prairie, where photographs and measurements were taken. They are produced without the intervention of any obstruction, and sometimes occur in groups or trains of waves comprising a hundred succeeding ridges. Their movement is sufficiently rapid to be readily visible. In certain conditions of the snow true ripples are also formed, which are similar to the ripples produced by wind in loose dry sand. In both ripples and waves the steeper face is on the lee side. In moist or coherent snow, such as usually falls in England, the wind carves the surface into ridges which have their steep face on the windward side.

AN outward and visible sign of progress in the arrangements for the British Antarctic expedition which in July or August will set out under the auspices of the Royal Society and the Royal Geographical Society, was shown by the successful launch of the *Discovery*, the ship specially built for the expedition, at Dundee on March 21. Lady Markham christened the vessel, which, when completed, will cost about 50,000*l.*; and at a banquet held after the ceremony Sir Clements Markham referred to the lack of geographical knowledge of Antarctic regions and the opportunities which will be afforded for the study of the great ice barrier. The purely exploratory work of the expedition will, of course, be of interest, and as that appeals to the public mind it is perhaps expedient to give prominence to it. But the necessity for the expedition lies in the absence of information concerning the natural history, physics and meteorology of the south polar regions, and it is with the provision made for the investigation of these subjects that men of science are most concerned. We are glad, therefore, to know that the scientific work of the expedition is in the hands of Prof. Gregory.

IN the House of Commons on Friday, Sir J. Rankin asked the President of the Board of Agriculture whether he would consider the desirability of establishing pomological stations in convenient parts of the country for the purpose of making experiments in the growth of the apple and pear, so as to enable persons employed in the fruit industry to obtain trustworthy information. In reply, Mr. Hanbury said: "Stations for agricultural and horticultural experiments have not hitherto been established directly by the State itself, and in the case of apples and pears, which depend so much upon the climate in which they are grown, no one central station would be of much use, and it is only by local agency that experiment stations could be established in so many varying districts. Both in the North and South of England there are institutions, aided either by the local taxation grants or by direct grants from the Board of Agriculture, in which experiments are made in the growth of pears and apples, and this appears to be the proper system to be adopted in those districts, such as Herefordshire, where there is a special interest in the growth of these fruits."

AN account of the work of M. Théodore Moutard, the mathematician, whose death was recorded last week in these columns, is given by M. G. Darboux in the *Comptes rendus*. After leaving the École Polytechnique, Moutard for a long time devoted himself to private teaching, preferring this course to serving under the Government, and he soon established for himself a unique reputation. But in 1870 he returned to the School of Mines, and he rendered valuable services as Inspector-General of Mines. The second part of his career was thus spent in the midst of a circle of congenial and distinguished colleagues. Moutard rarely published papers, but what he did write was of great value. To him we are indebted for the theory of anallagmatic surfaces, and especially of those of the fourth order or *general cyclides*, and Moutard's theory has formed the basis of numerous developments by Laguerre, Rebacour, Mannheim and Humbert. In the theory of partial differential equations of the second order, with two independent variables, Moutard gave a complete solution of an important problem. His manuscript, presented to the Academy, was burnt by the Communists at Bertrand's house; but Moutard re-wrote the most important portions, and the remainder of the theory was re-established by Cosserat. Moutard also wrote some valuable notes to Poncelet's *Applications d'Analyse et de Géometrie*, and his use of elliptic functions in connection with Poncelet's theorems on inscribed and circumscribed polygons has been characterised by Halphen as one of the best and most profound writings on this interesting subject. Moutard sought no distinctions, and never became a candidate for membership of the Paris Academy, although the section of geometry of that body recognised his merits by awarding him the Petit d'Ormoy prize, the highest honour that could be conferred on him. He kept a great many of his writings unpublished, although repeatedly urged to allow them to be printed.

IT is with much regret that we record the death, on March 7, of Mr. Arthur Coppen Jones, known to the scientific world as the translator of Fischer's "Lectures on Bacteria," and by an important paper, published in the *Centralblatt f. Bacteriologie und Parasitenkunde* in 1895, in which he sought to establish the revolutionary discovery that the tubercle bacillus is probably no bacillus at all, but a stage in some hyphomycetous fungus. Mr. Jones was one of the last set of students who worked under

Huxley at the Royal College of Science, and he there distinguished himself by taking the Forbes medal. Full of enthusiasm, he laid his plans to return to the College in the following session for the work of investigation, but an exceptionally severe constitutional breakdown prevented him from so doing. He was ordered to Davos, and he there spent the rest of his life, with the exception of brief periods of absence passed in study at the Universities of Zurich and Berlin, he being attracted to the latter city by the now famous investigations of Koch. While at Davos, Jones developed a practice as a consulting bacteriologist, working and experimenting whenever he was able. He did not hesitate to submit even his own person to experiment, and in one of his letters he admitted himself enamoured of the Richet muscle-plasma treatment, with which he experienced an immediate success. In the closing year of his life, Jones returned to some experiments he had previously made upon the physiological effects of air at high altitudes, but to no purpose, for the end came suddenly and peacefully, a tubercular cystic trouble necessitating an operation, which, while affording relief, proved of no permanent value. He was buried at Davos, where his loss will be severely felt.

WE have received a pamphlet setting forth in concise form a history of the progress and present status of the work of the Concilium Bibliographicum at Zürich, which for the past five or six years has been maintained at considerable pecuniary risk by Dr. H. H. Field, who in successive periods has had to face a deficit ranging from 5625 francs for each of the first three years to 224 for the last. The official foundation of the institution was by a vote of the third International Congress of Zoologists, at their meeting in Holland of 1895, and the experimental stage of its work has now passed. The Swiss Society of Naturalists, who have all along been among the foremost supporters of the undertaking, have with commendable enthusiasm induced the Swiss Government, by a recent vote of its Parliament, to increase five-fold a subsidy with which during recent years it has generously endowed the work. There is hereby insured the future permanence of the enterprise, which now becomes independent of the person of its present director. The pamphlet gives, in addition, an analytical table of the cards and other bibliographic materials which have emanated from the Bureau, and a register of the distribution of the cards in the chief divisions of the bibliography. Terms of subscription, an outline scheme for future development, with an ambitious programme for the present year, bring the pamphlet to a close, except for the remark that a removal has recently been made to more spacious quarters. Acknowledgment is made of support received from the Elizabeth Thompson Science Fund, and while we would congratulate Dr. Field upon this and the encouraging circumstances under which he starts work for the new century and wish him every success, we would recommend to the consideration of zoologists and bibliographers at home the fact that Cape Colony takes about as many cards as the whole of England. This is a condition which simply should not be, and denotes a poor return for the services done.

THE April Pilot Chart for the North Atlantic and Mediterranean has just been published by the Meteorological Council. It follows the same arrangement as that for the January specimen chart described in our last number. But of course there are, in all directions, important changes in the details. There are some interesting features connected with the winds and currents, particularly the modifications in the set of the currents off our western and south-western coasts, which are, no doubt, due to the prevalence of polar winds off the coasts of north-western Europe in the spring months, causing a surface drift to the westward and south-westward, and interfering with the normal flow of the Gulf Stream. Many subjects are dealt with in the letterpress, but prominence is given to fog and ice about the banks of Newfoundland, these dangers increasing with the opening of navigation of the St. Lawrence Gulf and River for the summer. It is explained that the fogs of this locality have certain peculiarities, the knowledge of which may be of no little service to the seaman. Thus, with the wind blowing from the sea towards the land, the fog is generally of no great density, for objects can often be sighted at a distance of half a mile, but with calm fogs following strong winds nothing can be seen at fifty yards from the deck, yet at a height of fifty or sixty feet in the rigging it may be possible, at the same time, to see almost any distance round. Up to the time of going to press no ice had been reported on the Grand Banks this season, the weather off St. John's, Newfoundland, on the 8th inst. being favourable, and no ice to be seen, so that it does not look like a great ice year.

FOR several years past the Deutsche Seewarte, Hamburg, has made strenuous efforts to accelerate and improve the service of telegraphic weather reports. The subject has been discussed both at international meetings and at conferences of the heads of the German meteorological systems, and it is recognised on all sides that the present service can be materially improved by a more speedy collection, discussion and publication of observations. So long ago as 1872 a very perfect system was introduced in the United States, called the circuit-system, in which the necessary wires over certain telegraph lines are reserved exclusively for the transmission of meteorological messages for a time after each observation. This method has been found to work very satisfactorily in the United States, but in Europe, where the control of the wires is in the hands of various countries, the difficulty of introducing a similar method is insurmountable. The system recommended by the Deutsche Seewarte is called the radial-system, in which the observations pass through the central offices. Special observations have been made for nearly a year at 8 a.m. mid-European time, or at about 7 a.m. Greenwich time, at some thirty-five stations in various countries, including several in the British Islands, and forwarded to the Deutsche Seewarte, which enable the Hamburg office to issue reports as early as 9 a.m.; and the early publication of this information has been found to lead to such satisfactory results as to warrant a considerable extension of the plan in the near future. The method is fully discussed and explained by Dr. van Bebber, in the February number of *Das Wetter*, in an article entitled "The Present Condition of Weather Telegraphy."

WE have received a copy of the year-book of the Austrian Meteorological Office for 1899, containing daily observations at twenty stations, hourly observations for Vienna, and hourly means and monthly and yearly summaries for a large number of stations. During each winter the Vienna thermograms show some anomalous jumps of temperature, amounting to 3° to 5° C. and at times reaching even to 10° in half an hour, or less. The mild winter of 1898–9 exhibited several such cases, and these have been made the subject of an interesting discussion by Mr. Max Margules, who has compared the thermograms of Vienna with those of two places situated some 30 or 40 miles to the east and west of that place. In very sudden rises of temperature it is a matter of considerable importance to know what is taking place above. In all cases it was found that at a relatively greater altitude, say 500 to 800 metres above the lower stations, the warmer temperature occurred some hours or even a day earlier than at the lower stations. The subject has been discussed with reference to the following conditions:—(1) A progressive increase of temperature in the upper air; (2) a constant temperature above; (3) an increasing temperature below with a decreasing temperature in the higher strata of the atmosphere.

THE remarkable subsidences which have often occurred in and around the town of Northwich, in Cheshire, form the subject of a paper by Mr. T. Ward, recently issued by the Institution of Mining Engineers. The subsidences are chiefly due to mining in the Upper Bed of rock-salt, and the too rapid removal of brine by means of modern pumps. In a natural condition the water in or on the salt-beds becomes saturated with salt and then ceases to dissolve it, but now the brine is continually pumped up in immense quantities, and the fresh water which flows to take its place dissolves the salt pillars which have supported the roof and overlying strata, with the result that there is a depression towards each pumping centre. In almost every case the mines in the Upper Bed of rock-salt are destroyed by water rapidly eroding the salt pillars in this way. Another cause of subsidence is the pumping of brine from off the rock-head, that is, the surface of the Upper Bed of rock-salt. These are by far the most serious and widespread, and it is from them that the town of Northwich suffers so much damage. Owing to the subsidences, which show themselves first by small cracks in the buildings, and in doors and windows refusing to shut, a system of framework buildings has been allowed, so that when a building sinks it can be lifted by screw-jacks and put back to its original position. By degrees the town is becoming one of framework buildings, and will, for England, be unique in this respect. The accompanying illustration, which we are enabled to give from Mr. Ward's paper, shows a subsiding house in a street at Northwich.

WE learn from the *Scientific American* that Mr. Edison has recently taken out a patent for a method of obtaining permanent phonographic records. The wax cylinder on which the impressions due to the speech have been made in the usual way is first coated with an extremely thin layer of gold; this is effected by revolving the cylinder in a vacuum between two gold electrodes between which a vacuum discharge is passing. This thin layer of gold is backed up with copper by electro-deposition and the wax is removed, we imagine by melting it off. Upon the copper matrix thus obtained a deposit of silver is thrown down electrolytically, and when this is of sufficient thickness the copper is dissolved off. The remaining silver deposit will retain the thin layer of gold and will be an exact reproduction of the original wax record, but one much more capable of standing repeated use. The value of the invention depends obviously on the fidelity with which the final silver record reproduces the original sounds; if the reproduction is accurate the process is a very useful one, since a phonographic record which is at once faithful and permanent should be of considerable value for historical purposes.

IN the February number of the *Victorian Naturalist* Mr. A. J. North continues his observations on the geographical distribution of Australian birds.

A RECENT issue of the *Bulletin* of the Illinois State Laboratory of Natural History (vol. v. art. 12) deals with the local fauna of leeches (Hirudinea), of which several new forms are described. The occurrence of certain European species is especially noteworthy. Several beautiful plates illustrate the morphology of some of the more remarkable types.

IN its Report for the past year the Oxfordshire Natural History Society and Field Club sets an excellent example to associations of a similar nature by the publication of the first instalment of a local fauna. The group dealt with on the present occasion is the Hymenoptera Aculeata, comprising ants, wasps and bees. The local list is also issued in a separate form, printed only on one side of the paper for cutting up to label collections.

DR. L. STEJNEGER sends us a copy of a paper on the North American wheatears (*P. U.S. Mus.* xxiii. p. 473), in which it is shown that a race of these birds habitually breed in North America. From the differentiation of this Greenland race the author thinks we are justified in inferring that the Greenland-Iceland-England line of migration must be considerably older than the Alaska-Tchuktchi-Udski route, since it has resulted in the establishment of the local variety of the wheatear forming the subject of this communication.

TWO papers in the March issue of the *Quarterly Journal of Microscopical Science* record important advances in our knowledge of the lancelets. In the first Dr. A. Willey describes a new subgeneric type of these primitive chordates from the Orissa coast, under the name of *Branchiostoma* (*Dolichorhynchus*) *indicus*. The distinctive characteristic is the anterior prolongation of the notochord and head-fin; so that this form is exactly the opposite of *Heteropleuron* (*Asymmetron*) *lucayanum*, in which these parts are extended in the other direction. In the second communication Prof. W. B. Benham describes the New Zealand lancelet as *Heteropleuron hectori*. It may be mentioned that, according to modern ideas of nomenclature, the name of the first subgenus of the typical group should be Branchiostoma, and not Amphioxus, which is a synonym.

To the same journal Mr. R. I. Pocock contributes an important memoir on the Scottish Silurian scorpion, with a figure of the specimen discovered in Lanarkshire in 1883. This the author makes the type of a new species, *Palaeophonus hunteri*. As the result of his investigations, Mr. Pocock concludes that Palæophonus apparently occupies a position intermediate between the king-crabs (Limulus) and the Palæozoic Eurypterids, on the one hand, and modern scorpions on the other, although, if anything, rather nearer the former than the latter. The Scotch species thus supplies a few more links to the chain of evidence connecting the line of descent of the modern terrestrial scorpions from marine ancestors more allied to the king-crabs.

We have the pleasure of congratulating Mr. T. Southwell, of Norwich, on the appearance, in the February number of the *Zoologist*, of the twentieth annual issue of his valuable "Notes on the Seal and Whale Fishery." The season's catch included 16 whales, 494 walruses, 53 seals and 145 bears, which yielded 230 tuns of oil and 219 cwt. of whalebone; in addition to which was the product of 1 whale, 138 walruses and 3400 seals, equal to 60 tuns of oil and 10 cwt. of "bone" from the Cumberland Gulf station. With oil at 22*l*. per tun, and sizable "bone" at 1400*l*. per ton, the estimated value of the take would be about 30,000*l*., as against 38,000*l*. in 1899. Owing to the bays in which they are usually beached being blocked with ice, no white whales were taken. Mr. Southwell is informed that the Greenland seas are not to be visited by any British whalers during the coming season. Commenting on the practical disappearance of the right whale from the Greenland seas, the author doubts whether this can be attributed to extermination, but is at a loss to determine where the remnant have gone. "As to the seals, the case is much more simple; the destruction year after year of a very large proportion, often virtually of the whole brood and of a large number of old seals in addition, congregated in a limited area, must inevitably tell in course of time, and sooner or later reduce the breeding pack to such an extent that they would be no longer worth pursuing, and even lead to their final extermination. This has doubtless, to a very large extent, been the case. The British vessels have quite abandoned the pursuit, and what there is left of the Greenland sealing is now quite in the hands of the Scandinavians, whose more economical outfits enable them to continue the struggle long after we have been driven from the field."

A BULKY volume just issued by the Government of India contains accounts of the trade carried by rail and river in India in the official year 1899–1900 and the four preceding years, compiled under the direction of the director-general of statistics.

A COLLECTION of tables showing the rainfall recorded on each day of every month from 1868 to 1899 at Dehra Dun has been issued by the Survey of India Department. The daily, monthly and annual means are also given.

THE following lectures will be given at the Royal Victoria Hall, Waterloo Road, during April, on Tuesday evenings:—"Waves and Oscillations," Mr. A. W. Porter; "Wild Nature at Home," Mr. R. Kearton; "Arctic Discovery," Captain Wiggins; "Our Field Crops as a Factory of Food," Mr. J. S. Dymond; "Facts about India: Plague and Famine," Mr. Birdwood.

WE have received a copy of *Kuhlow's German Trade Review and Exporter*. This paper is published in Berlin but is written in English, and contains some interesting translations from German and other technical papers on recent electrical work. The main object of the journal is to introduce German productions to foreign markets, and it is noteworthy as an example of the energy and perseverance with which the Germans are pushing their export trade.

THE *Rendiconto* of the Bologna Academy (iii. 1) contains a paper, by Prof. Ferdinando Paolo Ruffini, on the moments of inertia of a system of points not possessing a mass centre. The author examines, with the aid of certain formulæ already indicated by the late Prof. Beltrami, the disposition in space of the axes which in a given system of points having no mass centre (the sum of the mass constants being zero) have a given moment of inertia. The quadrics which are analogous to the ellipsoids of inertia in an ordinary system are also discussed.

IN a recent number of the *Revue générale des Sciences* Prof. A. Haller describes the contact process of sulphuric acid manufacture as used by the Badische Anilin- und Soda-Fabrik. In this process a mixture of sulphur dioxide and air is brought into contact with platinised asbestos at the proper temperature. The platinised asbestos is placed on perforated trays, supported in an upright tube which is so arranged that it can be heated or cooled by means of a current of air. The temperature at which the best results may be obtained depends upon the concentration of the sulphur dioxide and must be sufficiently high to start the reaction, but lower than the dissociation temperature of sulphur trioxide. A similar process has been in operation for a considerable time in this country and in Germany for preparing "Nordhausen" acid, but it has been found only workable when the mixture of sulphur dioxide and oxygen is pure, such as the mixture obtained from sulphuric acid by dropping it on to hot platinum. Presence of water vapour and other impurities causes the platinised asbestos to become inactive. In the Badische Fabrik process the sulphur dioxide is obtained by burning pyrites, and complete combustion of the sulphur and other oxidisable matter is attained by blowing jets of air and steam into the hot gas just as it issues from the burners. The gas is then washed and dried by passing through sulphuric acid. Before passing into the "contact" apparatus the mixture is examined optically, and must show no trace of cloudiness when viewed through a long tube. It is also chemically examined and must be free from arsenic. By proper regulation of the temperature up to 99 per cent. of the sulphur dioxide is converted into sulphur trioxide. The sulphur trioxide is dissolved in water, and for the production of acid of higher concentration than 60 per cent. the process is more economical than the lead chamber method. The claim is also made that better acid is produced, since it contains no arsenic, nitric compounds or lead.

THE additions to the Zoological Society's Gardens during the past week include a Rhesus Monkey (*Macacus rhesus*) from India, presented by Mrs. F. Page; a Green Monkey (*Cercopithecus callitrichus*) from West Africa, presented by Mrs. Horrell; a Senegal Touracou (*Turacus persa*), a Great-billed Touracou (*Turacus macrorhynchus*) from West Africa, presented by Mr. G. A. Corder; a Goshawk (*Astur palumbarius*), European, presented by Mr. C. Schaible; four Chameleons (*Chamaeleon vulgaris*) from North Africa, presented by Mr. W. F. Cornelius; a Lesser White-nosed Monkey (*Cercopithecus petaurista*) from West Africa, a Grey Ichneumon (*Herpestes griseus*) from India, deposited; a Tasmanian Wolf (*Thylacinus cynocephalus*) from Van Dieman's Land, received in exchange.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN APRIL.

April 1. 15h. 56m. Transit (egress) of Jupiter's Sat. III.
2. 8h. 23m. Minimum of Algol (β Persei).
3. 18h. 0m. Mercury at greatest elongation, 27° 48′ West.
4. 11h. 59m. to 13h. 18m. Moon occults B.A.C., 4531 (mag. 5·7).
7. 15h. 59m. to 17h. 19m. Moon occults ω^2 Scorpii (mag. 4·6).
7. 16h. 5m. to 16h. 20m. Moon occults ω^1 Scorpii (mag. 4·1).
15. Saturn. Outer minor axis of outer ring = 15″·96.
15. Venus. Illuminated portion of disc = 0·998.
15. Mars. Illuminated portion of disc = 0·924.
20–21. Epoch of Lyrid meteoric shower (Radiant 270° + 33°).
22. 10h. 5m. Minimum of Algol (β Persei).
22. 10h. 25m. to 11h. 11m. Moon occults χ^2 Orionis (mag. 5·9).
27. 7h. 40m. to 8h. 31m. Moon occults 19 Sextantis (mag. 6·0).
30. 10h. Jupiter stationary.

NEW VARIABLE STARS.—Mr. Stanley Williams announces the discovery of a new variable star in Perseus having the position

$$\left.\begin{array}{l}\text{R.A.} = \quad 3\text{h. } 17\text{m. } 51\cdot 80\text{s.}\\ \text{Decl.} = +\ 43^\circ\ 39'\ 55''\cdot 6\end{array}\right\}(1855).$$

The star is B.D. $+43^\circ\cdot 726$, catalogued as 8·9 magnitude, and is in the same field as Nova Persei with a low power.

The following magnitudes have been determined from photographs obtained with a 4·4-inch portrait lens.

1900.	Dec. 22	...	11·63 Mag.
1901.	Jan. 11	...	11·47
	25	...	10·97
	Feb. 11	...	10·87
	20	...	10·80
	28	...	10.53

The visual magnitude of this star is considerably brighter than the above photographic measures. Espin classes the star R in his "Stars with Remarkable Spectra."

Dr. T. D. Anderson announces a new variable in Andromeda, whose position is

$$\left.\begin{array}{l}\text{R.A.} = \quad 0\text{h. } 43\cdot 5\text{m.}\\ \text{Decl.} = +\ 33^\circ\ 35'\end{array}\right\}(1855).$$

The magnitude of the star has varied as follows:—

1900.	Oct. 5	...	$<$11·2
1901.	Feb. 16	...	10·7
	March 10	...	10·2.

Astronomische Nachrichten (Bd. 155, No. 3698).

LIGHT CURVE OF ALGOL.—Prof. A. A. Nijland, of Utrecht, contributes an article to the *Astronomische Nachrichten* (Bd. 154, No. 3695), containing the results of a numerous series of determinations of the brightness of Algol during its variation, and gives the light curve deduced therefrom. As shown, the variation is not symmetrical with respect to the minimum, a break occurring on the passage from maximum to minimum.

CHART FOR OBSERVATIONS OF NOVA PERSEI.—The first of a series of charts for use in observations of Nova Persei has been prepared by Father Hagen, of Georgetown College Observatory, and has recently been issued. The publication consists of a map of the region surrounding the Nova, showing stars down to the sixth magnitude, and a catalogue including all the stars shown on the chart, with their actual magnitudes and notes as to any peculiarities. A second series of charts is in preparation, and will be issued shortly.

PHOTOGRAPHY OF THE AURORA.

THE ever-changing form, and the faintness, of the aurora render this phenomenon a difficult subject to the photographer. Many have been the attempts to secure photographs of what have appeared to be brilliant displays, but the results have shown that little or no action had taken place on the photographic film, in spite of the fact that very rapid plates had been used. Herr Tromholt, who made a special study of the photography of the aurora, exposed very rapid plates to what he considered bright auroræ, and even with exposures from 4–7 minutes secured no trace of them. Later, at Christiania, he was more fortunate, and obtained an impression with an exposure of 8·5 minutes. To advance our knowledge of the changes in form of this phenomenon, it is important that photographs should be secured, if possible, in a few seconds, and not minutes. This seems now to be feasible, judging from an interesting account given in the *Meteorologische Zeitschrift* (Heft 6, 1900), by Herr O. Baschin. Herren Brendel and Baschin stayed several months, during the winter of 1891–92, at Bossekop, in Norwegian Lappland, to study the magnetic elements and the aurora.

For the photography of the aurora they employed an apparatus belonging to Herr. O. Jesse, who had used this instrument for photographing luminous night clouds. The objective had a focal length of 210 mm. and 60 mm. aperture; the dimensions of the plates used were 9 × 12 cm., the field photographed covering about 20° to 30°. Schleussner's plates were employed, and what appears to be the most important desideratum, the plates were stained (with erythrosine) and thus rendered more sensitive to the auroral light. For the first experiments the exposures given were comparatively long, namely three minutes, but these were found to be excessive; finally, seven seconds were sufficient to give good pictures. The reproductions accompanying the account of these researches illustrate the results secured with exposures of one minute and seven seconds respectively. The latter is reproduced here and shows very clearly the drapery-structure, although even this, according to Herr Baschin, is overexposed, the structure having a watery

FIG. 1.—Auroral-drapery on February 1, 1892.

and not sharp appearance. With such first results as these, there seems no reason why, with plates stained to be most sensitive to the particular colour of the aurora, and with the most rapid lenses, even shorter exposures of a second or less should not be given.

A step in the right direction has, however, been made, and the time is not far off when it will be as possible to project the ever-changing form of the aurora upon a screen as it is to exhibit in this way the phenomenon of an eclipse of the sun.

THE MISSISSIPPI RIVER.

THE Mississippi river, extending over a length of 2550 miles, has been placed by the United States Government under the charge of a Commission, whose duties include the making of a detailed survey of the channel from the headwaters to the Gulf of Mexico; a topographical survey showing the natural and artificial features lying within a mile of the river; a system of triangulation with base lines along the stream; longitudinal and cross sections of the channels; observations and records as to floods; and, for the assistance of future surveys, the placing, at intervals of three miles, of permanent marks, consisting of four stone or vitrified tile monuments placed in a line normal to the stream, two on each bank, about half a mile apart. The Commission has also the charge of the works carried out for regulating and deepening the channel.

Mr. J. A. Ockerson, who is a member of this Commission, and who, in the year 1899, made a survey of the headwaters of the Mississippi, contributed a paper on the subject to the *Proceedings* of the International Congress on Navigation held at Paris last year,[1] from which the principal part of the information here given has been obtained.

[1] "The Mississippi River: Some of its Physical Characteristics and Measures employed for the Regulation and Control of the Stream." By J. A. Ockerson, member of the U.S. Mississippi Commission Eighth Navigation Congress on Navigation. Recorded in English and French. (Paris 1900.

The Mississippi is one of the largest rivers in the world. It penetrates the heart of the most fertile portion of the United States for a distance of 2550 miles, and has 15,000 miles of navigable tributaries. Its headwaters rise amidst the pine-clad hills of northern Minnesota, where the long winters reach almost a polar cold, and winds its way through the varying conditions of climate of ten great States to the semi-tropical lowlands of southern Louisiana, finally losing itself in the Gulf of Mexico. Its drainage area, of over $1\frac{1}{4}$ million square miles, covers nearly half of the United States, and is equal to the whole of Europe exclusive of Russia. The region which it drains has no equal in any part of the world for fertility of soil and natural resources, such as vegetable products, timber, coal and minerals of various kinds. On its surface are borne immense cargoes of grain, coal and lumber gathered from the resources of a vast district and despatched across seas to all parts of the world. In its upper reaches it affords power to innumerable saw-mills and flour-mills and manufacturing industries.

The source of this great river has long been the subject of controversy. The earliest white explorers who first visited the country where the Mississippi rises were the French fur traders, but the earliest authentic account of the exploration of its source is that of William Morrison, who visited the district in 1804. The next explorer who recorded the results of his survey was R. H. Schoolcraft, in 1832, who located the headwaters in Lake Itasca. In 1872 the *New York Herald* sent a representative to visit the source of the river, with instructions to navigate the stream thence to the Gulf of Mexico. Again, in 1879, the *Louisville Courier Journal* sent an expedition to Itasca Lake. It was not, however, until 1889 that the first thorough exploration of the basin was made under the direction of the Minnesota Historical Society.

The State of Minnesota has set aside a reservation of 35 square miles, covering the basin of Lake Itasca, thus preserving for ever sacred the source of the father of rivers in the "Itasca State Park."

Unlike the origin of most large rivers which commence as mountain torrents, the Mississippi leaves its source with a width of 30 feet and a depth of 5 feet, and starts on its journey at an altitude of 1560 feet above sea-level. Commercial navigation reaches to within 25 miles of the lake, and thousands of sawn logs are floated down the stream every summer. At about 60 miles from the source the Government have constructed reservoirs, capable of holding 93,746 million cubic feet of water, for the purpose of regulating the supply of water to the channel and maintaining a navigable depth in summer. Near St. Anthony, about 500 miles from the source, are rapids which have been made use of obtaining water-power for working saw and flour mills and other manufacturing industries. Steamboat navigation commences near the junction of the Minnesota river, where the river has fallen 870 feet, 548 miles from the source.

A little above the junction with the Ohio, about 1400 miles down, the water becomes heavily charged with sediment and the country is subject to be flooded. The extreme range between high and low water at St. Louis is 37 feet. The slope of the water here falls six inches in a mile. Sand bars are numerous, and although the discharge amounts to 35,000 cubic feet a second in dry seasons there is not frequently more than four feet over the bars. Works are being carried out along this length for regulating the width of the channel and dredging away the bars so as to secure a better navigable depth. Where the banks are subject to excessive erosion they are protected by mattresses of woven willows, and the banks graded by hydraulic action. A description and illustration of this work was given in NATURE of December 19, 1896. Along this reach the river is exceedingly crooked. Between Arkansas and Greenville the distance along the river is 40 miles, the air line being only 15 miles. It also has great width, the banks, which are from 30 to 40 feet high, being in places two miles apart. The maintenance of these "levées" or banks is of vital importance to the surrounding country, as a breach would result in the inundation of 50,000 square miles of rich alluvial land.

One of the greatest difficulties which the management and the navigation has to contend with is the immense amount of drift-wood carried down in floods. This wood, if not cleared away, gets caught in the bends and accumulates, forming with the alluvial matter an effective barrier to the flow of the water and a source of danger to the banks. For the removal of this drift-wood special vessels, called snag-boats, are employed, which patrol the river and remove the snags.

Dredgers of large type, and provided with very powerful machinery, are in constant employment for removing sand bars and shoals. The type now almost universally in use for this purpose are worked by centrifugal pumps, which raise the sand and in some cases deliver it over the banks. Where the material is hard, cutters are provided at the end of the suction pipes of the pumps, which loosen the clay or hard material sufficiently to allow of its being sucked into the pipes. One of the most recent of these machines is capable of raising more than 4000 cubic yards of material an hour, and is fitted with electric light, machine shops, and all appliances necessary to repair the machinery and keep it in going order.

For the lower part of its course the river winds its way through a vast delta, twisting and turning by numerous bends until it extends its length to nearly double the point to point length of the delta. This delta is 500 miles long, and from 30 to 40 miles in width, covering an area of 400,000 square miles. It is composed of material transported by the current and deposited in the estuary, which at one time extended from the original outfall to the Gulf of Mexico. The river is still pouring solid matter into the Gulf, where it is spread out in a fan-like shape over a coast-line of 150 miles and is filling it up at the rate of 362 million tons a year. Some idea of the vastness of the silent operations of nature may be conceived when the fact is considered that this solid matter consists of the wearing away of the land through which the river flows, and that some of it must have been transported a distance of over 3000 miles; and that if the whole of it had to be carried in boats for half the total distance at the lowest rate at which heavy material is carried on the inland waterways of America, or, say, for one-tenth of a penny per ton per mile, the annual cost of transport would amount to no less a sum than 238 millions of pounds.

The channel in the lower reach is narrow, not exceeding half an mile in width, the depth in places exceeding 200 feet, and everywhere sufficient to float large sea-going craft as far as the junction of the Red river, a distance of more than 300 miles.

On this length is situated the city of New Orleans, 110 miles above the Gulf of Mexico. Ships of all nations reach this port. Its wharves extend over fifteen miles of river front, and are crowded with vessels of every description. Grain and cotton form the chief item of export.

As the river approaches the Gulf it is split up into three principal channels. The smaller of these has been improved by training walls made of mattresses and stone, which extend over the bar out into the deep water of the Gulf for more than two miles. This work was undertaken by Captain Eads, under contract with the Government to provide, for a certain sum of money, a depth of twenty-six feet at low water and to keep and maintain this depth for a period which has now expired.

The description of this mighty river above given will surely warrant its being called the "Father of Waters."

W. H. WHEELER.

HISTORY AND PROGRESS OF AERIAL LOCOMOTION.[1]

WHILE history contains no records of any past age in which men rode bicycles, the question of aërial locomotion has occupied the thoughts of man from the days of the Egyptians, to whom we are indebted for a representation of a man with wings considerably resembling the gliding machine on which Mr. Pilcher lost his life. Passing by the legend of Daedalus, whose invention of sailing ships led to the tradition that he attached wings to himself, we find in history numerous records, some such as that of Dante of Perugia or the chronicle of Busbequius, referring to gliding experiments which may not improbably have been authentic, others describing machines by which men have tried to raise themselves by their own exertions, but without success, as exemplified by Besnier, the Marquis de Bacqueville, Jacob Deghen, while a far larger number have been handed down to us of designs of fantastic machines for navigating the air, of a purely visionary character. In the latter category we must include in past times the grotesque figures

[1] Abstract of a Discourse delivered at the Royal Institution on Friday, February 8, by Prof. G. H. Bryan, F.R.S.

designed by Barthelemy Lourenço in Portugal, by the novelist Retif de la Bretonne, by Blanchard, before he became noted as a balloonist, and the prospectus of the Minerva issued by one Robertson when interest in ballooning was at its height. Even in recent times equally absurd devices have been promulgated, such as aërial tramcars supported by cigar-shaped gas vessels, not one-hundredth of the size necessary to raise such loads, and seats in such aërial tramcars with cavities filled with gas whose actual lifting power would amount to a few milligrams, and others.

The problem of aërial navigation, *i.e.* of performing *directed* journeys in the air, made no progress until Montgolfier's invention of the balloon. This rendered it possible to ascend in the air, but did not enable the motion to be directed, and from that time on aëronauts became divided into two classes: those who sought to navigate the air with balloons that rendered their apparatus lighter than air, and those who experimented with machines heavier than air but supported on structures resembling wings.

Balloons have often proved invaluable in times of war, and the war in South Africa has been no exception, thanks partly to the exertions of Major Baden-Powell. But the most practically useful application of the balloon in times of peace was inaugurated by Glaisher's ascents into the upper regions of the atmosphere for the purpose of obtaining meteorological data, and it is only recently that the balloon has been superseded for this purpose by the kite now largely used in America.

The experiments of Count von Zeppelin last summer, amounting as they did to the performance of a directed journey through the air, in some cases against a head wind, enable us to say that a solution of this problem was obtained before the end of the nineteenth century. The only previous achievement approaching von Zeppelin's was that of Messrs. Renard and Krebs in 1885 with the French war balloon, "La France." These experimenters on one occasion actually succeeded in performing a journey in the air and returning to the starting-point; but as the feat was never repeated and the speed of their balloon is stated by one writer at four and by another at fourteen miles an hour, it is somewhat difficult from such conflicting evidence to estimate the amount of success achieved. The speed attained by Count Zeppelin's balloon was about eight metres per second, say seventeen and a half miles an hour, and agreed very closely with that predicted by calculation, viz., 8·12 metres per second. With lighter and more powerful motors Count Zeppelin hopes to increase the speed by 50 per cent. The chief features of this machine are (1) its division into seventeen compartments, which prevents the gas from collecting at one end or oscillating in the balloon in such a way as to increase the resistance; (2) the distribution of the load at two points instead of at the centre, which reduces the mechanical difficulty of supporting a heavy weight by a cigar-shaped balloon.

The subject of dynamical flight without the aid of balloons opens up three fields of study:—(1) experiments on the air-resistance of planes and curved surfaces, systems of such aëroplanes and aërocurves variously arranged, and propellers; (2) the construction of motors of minimum weight per horse-power, using the sources of energy of minimum weight per foot-pound; (3) experiments on the balance, stability and control of aëroplanes and aërocurves. A historic retrospect of the work done in the past century includes Captain Le Bris's gliding experiments with his "artificial albatross" in 1854; De Villeneuve's reported feat of raising himself into the air, in 1870, by a machine driven by steam supplied from a flexible hose; the experiments on air resistance conducted in 1871; Langley's confirmation, in 1891, of Duchemin's formula for the thrust of an oblique current on a plane area, and his proof of the law according to which the horse-power per unit of weight lifted decreases with the speed; and Phillips's Wealdstone experiments on the advantages of narrow superposed planes over wide planes of equal area.

Coming to the question of horse-power, the chief interest in Sir Hiram Maxim's famous experiments centred round his engine, with which he obtained 362 horse-power, the machine weighing about 8000 lbs. Langley and Hargreave are stated to have designed motors weighing 7 and 10 lbs. per horse-power respectively; while Da Pra has made theoretical calculations in connection with designs of an aërial machine from which he concludes that such a machine could be made capable of carrying a motor weighing 15 kilograms per horse-power. A more experimental treatment of the question of horse-power is afforded by estimates of the rate at which work is done by gravity in the gliding experiments of Lilienthal, Pilcher and Chanute, from which it appears that about 2 horse-power would be required to support the machines. Mr. Chanute further estimates the possible weight of the motor per horse-power in a one-man machine at 4 lbs. for screws, 8 lbs. for wings, and 14 lbs. for aërocurves.

But the most difficult question connected with the flying machine is its balance and stability under the conditions ordinarily prevailing in our atmosphere. The very fluctuations of wind velocity which may furnish a source of energy for birds in sailing flight vastly increase the danger of experiments on artificial flight. It is easy to construct a glider which when dropped in a room from any position will right itself and begin to glide before reaching the ground; but the same glider when let fall from a window will continue to roll over and over and fall to the ground. More than thirty years ago Mr. Wenham made a model which would glide well from a window, but when let fall from a balloon in one of Glaisher's ascents it overturned after descending twelve yards.

Of the three, Lilienthal, Pilcher and Chanute, who have done most to solve this question of balance and stability, the two first met with fatal accidents just when their experiments were becoming most successful, and we are naturally led to compare their methods with those adopted by Mr. Chanute.

Both Lilienthal and Pilcher used machines with broad curved wings, the former preferring two superposed aërocurves and the latter adopting a single-surfaced machine. In both machines the wings were rigidly fixed, the operator relying on the movements of his body to counteract the effects of any sudden gust of wind tending to overturn the machine. Chanute, on the other hand, experimented with narrow superposed wings, some of his machines having as many as eleven or twelve aërocurves, arranged in pairs. Instead of balancing himself by his own agility, the wings were movable about pivots and were held in position by springs in such a way that their displacements, caused by a sudden gust of wind, gave the machine a tendency to right itself. Finally, a two-surfaced machine with narrow superposed rectangular surfaces, also with automatic balancing arrangements, was devised by Mr. Herring. With this machine, gliding was possible in winds of 31½ miles an hour, the greatest wind velocity in Lilienthal's experiments having been only 22 miles an hour, and little practice was required to control the machine. Practically no motions of the body were needed when a gust of wind struck the machine in a fore and aft direction, and but little movement was needed in the case of a side gust. The longest glide was 927 feet, and was performed by "quartering," *i.e.* sailing parallel to the side of a hill up which the wind was blowing.

The experiments of Messrs. Chanute and Herring constitute a distinct advance in the construction of gliding machines, and lead us nearer to the possibility of obtaining a true flying machine propelled by a motor. The addition of such a motor, if only by increasing the weight of the apparatus, would largely add to the difficulty of controlling it in the first trials, and the action of the propeller might considerably affect the balance. It is not improbable that after the first start is once made, the motor-driven machine may prove to possess greater steadiness in flight than the present gliders. In the former the thrust of the propeller is fixed relative to the body, in the latter the only motive force, due to gravity, is fixed in space, and Mr. Herring's experiments indicate greater stability under the first-named condition. How to perform the first experiments with the motor-driven machine is the difficulty which now awaits solution. If a large motor be used, the machine becomes too heavy to be readily controllable; if the dimensions of the machine are kept down it becomes the more difficult to construct a sufficiently light and powerful motor. The automatic regulating mechanism of Messrs. Chanute and Herring, by minimising the effort required in ordinary balancing, may render it possible for a man possessing the gymnastic skill of a Lilienthal or a Pilcher to overcome by his agility the new difficulties, introduced, at least in its early stages, by the motor. But in the transition from the gliding machine to the flying machine proper a wide gap has to be bridged, and it is little wonder that experimenters hesitate before taking a step which may introduce unforeseen dangers. It is by reducing the difficulty of balancing large machines, on the one hand, and reducing the weight of motors on the other, that we must hope to arrive at an experimental demonstration of the possibility of artificial flight.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

MR. W. E. THRIFT has been elected Erasmus Smith professor of natural and experimental philosophy in Trinity College, Dublin, in succession to the late Prof. G. F. Fitzgerald.

WE are glad to notice in the report of the committee of the Bristol Museum that interest in nature study is encouraged by various means. In one of the rooms of the Museum, three aquaria containing the ova of the common frog, and the common and crested newts, were arranged, in order that the various stages of development passed through by these forms might be seen by visitors. The aquaria proved of especial interest to young people from schools. Lectures have been given by Mr. H. Bolton, the curator, to the students of evening continuation schools, and the Museum has been visited by a number of classes from other schools. The committee record that definite steps have been taken to provide the additional accommodation that has long been needed. The proposal took the form of providing for museum extension in conjunction with the establishment of a municipal art gallery, and the generosity and public spirit of Sir William Henry Wills has made this possible. Upon the basis that the sum of about 30,000*l.* would be required to provide a suitable building for both purposes, Sir W. H. Wills offered that if 10,000*l.* were provided for museum extension on the site adjoining the present building, he would provide for the completion of the scheme. This munificent offer was accepted by the council, who also accepted a report of the joint libraries and museum committees recommending the requisite application to Parliament, and placing the administration of the proposed art gallery in the hands of the museum committee.

IN connection with the London School of Economics and Political Science, Lord Rosebery delivered an address on commercial education at the Mansion House on Thursday last. The Lord Mayor, in opening the proceedings, stated that the object of the school was to provide a scientific training in the structure and organisation of modern industry and commerce and the general causes and criteria of prosperity as they were illustrated or explained in the policy and the experience of the British Empire and foreign countries. Mr. Passmore Edwards had generously contributed 10,000*l.* towards the erection of a building for the faculty of economics and political science; and Lord Rothschild had given 5000*l.* In the course of his address, Lord Rosebery said: "From whatever standpoint we may regard the age, I think we must all be aware that we are coming to a time of stress and of competition for which it is necessary that we should be fully prepared. It is not necessary here to indicate what form that stress or that competition may take, but in military matters, in naval matters, in commercial matters, in educational matters, we see more clearly day by day that we shall not be allowed to rest on any reputation that we possess already, but that we shall have to fight for our own hand in every department of human activity and human industry if we wish to keep our place. It is necessary for a nation in these days to train itself by every available method to meet the stress and the competition which is before it. Lord Salisbury said the other day—and I think with some truth—that it was impossible to define technical education. Well, I do not think it is impossible, but I think it is difficult. The way in which I should define it—very imperfectly, I am aware—is this. I should define it as education having a direct practical bearing on any definite industry or calling; that is to say, an education, not as we are accustomed to see secondary education as carried out in this country—an education for the training and elevation of the mind—but a practical training having a business bearing." The United States Ambassador, in proposing a vote of thanks to the Lord Mayor, said there was no doubt that colleges of economics and of political science were the latest development in the theory and practice of that education which was to fit men for the great affairs of life as they were developing in the complex and rapidly varying phases of modern civilisation. In the United States they regarded them as among the chief means of maintaining their part in that rivalry which they were maintaining, and meant to maintain with all their force, with their sister nations of the world, and especially with this country, to which they were so much attached—a rivalry not of arms or of warfare, but a rivalry of brains, of skill, of courage in the great industries of life.

SCIENTIFIC SERIALS.

Transactions of the American Mathematical Society, vol. ii. No. 1.—Invariants of systems of linear differential equations, by E. J. Wilczynski. The author has elsewhere shown that the most general point-transformation, which converts a system of n homogeneous linear differential equations into another of the same form and order, is

$$x = f(\xi),\ y_k = \sum_{i=1}^{n} \alpha_{ki}(\xi)\eta_i \ . \ . \ . \ (k = 1, 2, \ . \ . \ n),$$

where $f(\xi)$ and $\alpha_{ki}(\xi)$ are arbitrary functions of ξ, and the determinant $|\alpha_{ki'}(\xi)|$ does not vanish identically (*American Journal of Mathematics*, January 1901). In the present paper he considers those combinations of the coefficients of a system of linear differential equations which remain invariant when the system is transformed by the above transformation. These transformations form an infinite continuous group, and the author employs Lie's theory throughout, as Dr. Bouton has done in the *American Journal of Mathematics*, vol. xxi. No. 2. The applications of the theory are but lightly touched upon, and only a passing mention is made of covariants (p. 23) in this (first) paper.—Divergent and conditionally convergent series whose product is absolutely convergent, by Florian Cajori. Tests of the convergence of the product of conditionally convergent series have been worked out by Pringsheim, A. Voss and by Cajori (see *American Journal of Mathematics*, vol. xv. and vol. xviii., and *Bulletin* of the American Mathematical Society, vol. i. (1895). Two typical examples are discussed and also the author's general method.—Sets of coincidence points on the non-singular cubics of a syzygetic sheaf, by M. B. Porter. The points where a cubic can have an eighth order contact with cubics of the syzygetic sheaf are called by Halphen coincidence points of the cubic. The author considers certain geometrical relations that subsist between an inflexion triangle and its associated group of in- and circumscribed rectilinear triangles. The number of these triangles is 24. We give one property. Each in-circumscribed triangle is in six ways perspective with its associated inflexion triangle.—Note on non-quaternion number systems, by W. M. Strong. All number systems have been divided into the quaternion and non-quaternion systems, and Scheffers has shown that the n fundamental units of a non-quaternion system may be so chosen that the multiplication table takes a particularly simple form, which is in turn characteristic of the non-quaternion systems. The present paper shows that the choice of the units may be so regulated that the multiplication table becomes still simpler.—On the reduction of the general Abelian integral, by J. C. Field, embodies results (in 38 pp.) which were presented at the annual meeting of the Society held in 1897. MM. Appell and Goursat, in their "Théorie des fonctions algébriques et de leurs Intégrales" (pp. 344-345) give a brief sketch of Hermite's method for obtaining by rational operations the reduced form for a hyperelliptic integral, in which note they make a remark which seems to imply that the more general problem in the case of the Abelian integrals was still awaiting a solution. The present paper is the auth r's solution of the problem.—"Ueber flächen von constanter Gausscher Krümmung," by D. Hilbert. The greater part is concerned with Flächen von negativer and the rest with Flächen von positiver constanter Krümmung (*cf.* Dini, *Annali di Mat.* Bd. 4. 1870; Darboux, "Leçons sur la théorie générale des surfaces," Bd. 3, and Bianchi, "Lezioni di geometria differenziale").—A short note follows on the functions of the form $f(x) \equiv \phi(x) + a^1x^{n-1} + a_2x^{n-2} + \ . \ . \ . \ + a_n$ which in a given interval differ the least possible from zero, by H. F. Blichfeldt. This gives Tchebycheff's solution (from Bertrand, "Calcul differentiel," p. 512) and then the author's solution. As this gentleman has not had access to Tchebycheff's memoirs his method may not be altogether novel.

Annalen der Physik, March.—On the production and measurement of sinoidal currents, by Max Wien. The ideal electrical oscillations for use in wireless telegraphy would consist of a continuous, purely sinoidal current, the oscillation frequency of which could be varied slowly and continuously from a low figure up to frequencies that could be seen. The arrangement described in the present paper, although still far short of this, constitutes a considerable advance upon previous work, as a purely sinoidal current can be obtained with an oscillation frequency up to 8500 per second, and with a slight depar-

ture from the sine form, up to 17,000. The methods and special instruments for the exact measurement of these currents are also given.—The acoustical and electrical properties of the telephone, by Max Wien.—On the theory of rain precipitation in mountains, by F. Pockels. The conclusion is drawn from theoretical considerations that on the slope of a mountain chain there exists a zone of maximum precipitation, and that the inclination as well as the absolute height has an effect upon the amount precipitated. Both these conclusions are in agreement with observations upon the higher mountains.—The effect of current fluctuation, of electrical oscillations, and of an induced current upon a magnetic needle placed in a constant field, or upon a small soft iron inductor, by Max Hornemann.—Some results of capillarity phenomena, by A. Einstein.—On the so-called liquid crystals, by G. Tammann. It is shown that the effects produced by the so-called liquid crystals may be explained by the assumption that there is really present a mechanical mixture of two liquids. A partial separation was effected in the case of *p*-azoxyanisol.—On some experiments with the Becquerel and Röntgen rays, by F. Himstedt. The sparking distance for an influence machine is affected by both the radium rays and the Röntgen rays. The failure of Elster and Geitel to observe the latter effect is attributed by the author to the use of too small a Crookes' tube.—On the action of the Becquerel and Röntgen rays on the eye, by F. Himstedt and W. A. Nagel.—On the law of the distribution of energy in the spectrum, by Max Planck.—On the elementary quantity of matter and of electricity, by Max Planck.—Studies in hardness, by W. Voigt.—On characteristic curves in the electrical discharge through rarefied gases, by E. Riecke.—Experimental researches on the metallic reflection of electrical oscillations, by Karl F. Lindman.—On the distribution of electricity on an ellipsoid, by H. Dörrie.—On the transparency of hydrogen to light, by V. Schumann.—On the fundamental hypothesis of the kinetic theory of gases, by S. H. Burbury.—Remarks on the paper of E. v. Schweidler on the behaviour of liquid dielectrics on the passage of an electric current, by E. Warburg.

SOCIETIES AND ACADEMIES.

LONDON.

Physical Society.—Meeting held in University College, March 22.—Prof. S. P. Thompson, president, in the chair.—A paper on the expansion of silica was read by Prof. Callendar. The extreme smallness of the thermal expansion of silica (fused quartz) renders the determination of its coefficient of expansion more difficult than is the case with many substances. The author has made experiments upon a rod of pure silica 40 cms. long and 1 mm. diameter. This rod was enclosed in a platinum tube about 3 mms. diameter, which could be raised to various temperatures by the passage of a suitable electric current. Both the rod and the tube were firmly fixed at one end, and the positions of the other ends were accurately observed by a micrometer microscope reading to a thousandth of a mm. The expansion of the tube, in conjunction with a knowledge of its coefficient of expansion, served as a means of determining the temperature of the tube, and, therefore, of the rod. The increase in length, the original length and the range of temperature of the silica being known, the coefficient of expansion can be at once calculated. In some previous experiments the author has investigated the distribution of temperature along a heated platinum rod subjected to cooling at the ends. These experiments prove that the error due to end effect, in the case of the silica rod, can be neglected. The expansion of silica up to 1000° C. is regular, and is about one-seventeenth that of platinum. Between 1000° C. and 1400° C. silica expands more quickly than below 1000° C., and if left at any temperature for a considerable time continues to slowly increase in length. If a curve be plotted having temperatures as abscissæ, and increases in length as ordinates, a straight line will represent the expansion of silica up to 1000° C. Above 1000° C. the curve bends upwards, and upon cooling it returns along a path above the ascending curve, so that the final length of the bar is greater than the original length when the lower temperature is reached. The determination of the coefficient of expansion at these high temperatures was made by means of a variable zero, that is by using for the length of the rod that obtained by suddenly cooling from the higher to the lower temperature. At 1400° C. the properties of silica alter and the expansion is replaced by a contraction. On cooling from above 1400° C. to ordinary temperatures there is first an expansion and then a contraction. This property was illustrated by Prof. Callendar, the small changes in length of the rod being magnified by a lever and shown upon a screen by an optical arrangement. The critical point at which contraction occurs on heating has been found by Le Chetalier at about 800° C. His experiments were made by a differential method, using porcelain as a standard substance. As the expansion of porcelain is uncertain, the author thinks it probable that the effect noticed may be due to irregularities in the expansion of porcelain rather than in that of silica. Mr. Boys expressed his interest in the experiments and asked if the small coefficient of expansion of slate had ever been measured. The small expansion of silica would make it a useful suspension for pendulums on account of the small compensation necessary. Its perfect elastic properties might be made use of in hair springs for chronometers. Prof. Threlfall said that he had tried to measure the expansion of silica between 0° C. and 70° C. by weighing rods in distilled water, but the method was not accurate. He had made experiments similar in principle to the author's, using temperatures from 0° C. to 100° C. The devitrification of silica is troublesome, and he thought that the rate of devitrification in presence of air increased with the temperature. Dr. Donnan thought that the irregularities in the expansion of silica pointed to a complex composition. Mr. Porter (Eton) asked if the effect of fused quartz on polarised light had been investigated, and if this effect altered after heating to 1400° C. Mr. Boys said that quartz rods formed by fusion depolarised light. The chairman said that he had noticed the effect spoken of by Mr. Boys, due to strain, but he had been unable to detect any rotatory power. Prof. Callendar, in reply to Mr. Lupton, said that the expansion of quartz crystals was much larger than that of fused silica.—The spectroscopic apparatus of University College was then exhibited by Dr. Baly.—The Society then adjourned until April 26.

Chemical Society, March 7.—Dr. Perkin, vice-president, in the chair.—The following papers were read:—Nomenclature of the acid esters of unsymmetrical dicarboxylic acids, by J. J. Sudborough.—Additive compounds of α- and β-naphthylamine with trinitrobenzene derivatives, by J. J. Sudborough. The author describes a number of additive compounds of red or purple colour which are formed from derivatives of trinitrobenzene and the naphthylamines, and are more stable than such compounds as those of trinitrobenzene and aniline.—Acetylation of arylamines, by J. J. Sudborough. It is shown that the presence of ortho-substituents, whether of positive or negative character, accelerates the formation of diacetyl derivatives of primary arylamines.—Formation of amides from aldehydes, by R. H. Pickard and W. Carter. On oxidising an aldehyde with ammonium persulphate in presence of lime, a 30 to 40 per cent. yield of the amide of the corresponding acid is obtained.—A method of isolating maltose when mixed with glucose, by A. C. Hill. The author gives a method for separating maltose from a mixture of glucose and maltose based upon the fact that *Saccharomyces marxianus* destroys the former, but leaves the maltose untouched during its growth in a solution of the mixed sugars.—The vapour pressure of aqueous ammonia solutions, by E. P. Perman. The author has determined the vapour pressures of aqueous ammonia solutions between the temperatures 0° and 60°, and for concentrations up to 35 per cent.—The influence of sodium sulphate on the vapour pressure of aqueous ammonia solution, by E. P. Perman. The vapour pressure curves of aqueous ammonia containing sodium sulphate afford no indication that the latter exists as a hydrate in the solution.—Formation of aromatic compounds from ethyl glutaconate and its derivatives. The reduction of trimesic acid and the conversion of tetrahydrotrimesic acid into tetrahydroisophthalic acid, by W. T. Lawrence and W. H. Perkin, jun. Ethyl sodiodicarboxyglutaconate, $(COOEt)_2CNa.CH:C(COOEt)_2$, heated with alcohol at 150°, yields ethyl trimesate, and ethyl glutaconate, under similar conditions, is converted into a substance which on hydrolysis gives hydroxyisophthalic acid. Trimesic acid is reduced by sodium amalgam to a mixture of stereoisomeric tetrahydrotrimesic acids, of which one has been isolated in a pure state; this gives a double anhydride with acetic anhydride, which, when distilled, yields tetrahydroisophthalic anhydride.—Optical activity of certain ethers and esters, by P. A. Guye.—Halogen-substituted thiosinamines, by A. E. Dixon. The author describes a number of chloroallylthiocarbimides.—A form of tautomerism occurring amongst the thiocyanates of electro-negative radicles, by A. E. Dixon.

Geological Society, March 6.—J. J. H. Teall, V.P.R.S., president, in the chair.—Recent geological changes in Northern and Central Asia, by Prof. George Frederick Wright. The present paper is the outcome of a journey made by the author in company with Mr. Frederick B. Wright in 1900-1901. In North America an area of about 4,000,000 square miles was brought under the direct influence of Glacial ice during the Glacial epoch. The result of six weeks spent in Japan was to show that there are no signs of general glaciation in Nippon or Yesso. Neither is there any sign of glaciation along the border of the Mongolian Plateau, where the general elevation is 5000 feet, but the whole region is covered with lœss. This has usually accumulated like immense snow-drifts on the south-eastern or lee-side of the mountains, and in it houses and villages are excavated. In the mountainous region, strata of gravel and pebbles are so frequent in the loess that it is necessary to invoke both wind and water in order to explain fully the origin of the deposit. At the present time the loess in the interior is being washed away by streams much faster than it is being deposited by the wind. The journey across Manchuria from Port Arthur along the Lao-Ho and Sungari rivers was through valleys choked with alluvium, and there was no evidence that the drainage of the Amur had ever been reversed by ice, like that of the St. Lawrence; nor was there any other evidence of glaciation. The lower course of the Amur indicates subsidence. Again, there are no signs of glaciation on the Vitim Plateau. Lake Baikal appears to be of recent origin; it is 4500 feet deep and has not been filled by the great quantities of sediment brought down by the Selenga and other rivers. Although glaciers could frequently be seen on the mountains which border the Central Asiatic Plateau to the north-west, there was no evidence that the glaciers had ever deployed on the plain. The loess-region of Turkestan, and indeed the whole area from the Sea of Aral to the Black Sea, appears to have been recently elevated, in some places as much as 3000 feet. Desiccation took place at the same time, so that the larger lakes are only brackish or still fresh. Direct evidence of this in the form of deposits is given. The author thinks it likely that the absence of glaciation in Northern Asia may have been due to the rainlessness of the region, and that while America was elevated, Asia was depressed during the Glacial Epoch.—The hollow spherulites of the Yellowstone and Great Britain, by John Parkinson. A recent journey to the National Park of the United States, resulting in a study of the obsidians and rhyolites in the field and at home, suggested a direct comparison between the hollow spherulites characteristic of these rocks and those of the rhyolites of Shropshire, Jersey and elsewhere. Hypotheses framed to account for the varying structures of spherulites are: (1) Hollow spherulites are the result of some property of the original magma, or (2) are due to the decomposition of an originally solid spherulite by heated waters. Taking the second alternative first, a description is given of the effect of solfataric action on the rhyolites of the Yellowstone Cañon. The conclusion reached is "that the action of hot waters charged with silica may be to remove portions of the rock, or to permeate it without destroying its characteristic structure; that we obtain, however, no evidence to show that the spherulites are most easily attacked, but rather the reverse." Explanation, therefore, is most naturally sought in some property of the original magma, and that propounded by Prof. Iddings appears the nearest in accord with facts. Exception is taken to certain physical processes postulated by Prof. Iddings in a recent memoir, but with his earlier work the present writer is substantially in agreement. In the second part of the paper direct comparison is drawn between the structures exhibited by the hollow spherulites from Obsidian Cliff and those of examples from Shropshire, Jersey and other localities. Taking into consideration the resemblances between the hollow spherulites of the Yellowstone region and those of Great Britain, the conclusion is drawn that the hypothesis of corrosion is as inapplicable to the latter as to the former. On the contrary, the author believes that the cavities of the spherulites are the result of the hydrous state of the magma.

Royal Microscopical Society, February 20.—Mr. A. D. Michael, vice-president, in the chair.—A photograph of *Amphipleura pellucida*, taken by Mr. Brewerton, was exhibited.—Mr. Nelson said the photograph was interesting because it showed the transverse striæ as thin in comparison with the spaces between them. Some optical theorists maintained that the striæ and spaces must be of equal width, whereas he had affirmed that the striæ were much finer than the spaces. In many photographs of this object they appeared to be of equal width, but that was because the object had been badly photographed. In the example before the meeting the photograph had been properly taken, and therefore exhibited the difference in the thickness of the lines and the inter-spaces.—Mr. Rogers brought to the meeting a contrivance for exhibiting a fly in the act of feeding. This differed in some respects from Mr. Macer's arrangement for a like purpose, being a brass-plate, 3″ × 1″, underneath which a brass cone was soldered to contain the fly, the plate lying on the stage of the microscope like an ordinary slide.—Mr E. M. Nelson read a paper on the tube-length of the microscope, explaining the difference between the mechanical and optical tube-length, illustrating the subject with drawings and formulæ.—The chairman thought there was no subject connected with the technique of the microscope about which ideas were more vague than that of the tube-length; many thought it was the length of the brass tube. Although it had often been pointed out in that room that what was really meant was the optical tube-length, the subject did not seem to be very well understood, very little practical information had been published which would enable a person to ascertain the tube-length of his microscope but Mr. Nelson had now given them a method by which this could be found.—Mr. F. W. Millett's report on the recent Foraminifera of the Malay Archipelago was taken as read.—The chairman called attention to a set of slides of bacteria and blood parasites which were exhibited by Mr. Conrad Beck.—Some mounted rotifers, sent from Natal by the Hon. Thos. Kirkman, were also exhibited.

Linnean Society, March 7.—Prof. S. H. Vines, F.R.S., president, in the chair.—Mr. F. Enock showed a series of lantern-slides illustrating the metamorphoses of a dragonfly, *Æschna coerulea*, and gave an interesting account of the life-history of that insect.—Mr. H. E. Smedley exhibited and made remarks on a collection of models of fungi, *Nepenthes*, *Sarracenia* and aroids, as also several models of sections of flowers, in wax and composition.—Dr. J. Murie, on behalf of Mr. H. Doubleday, exhibited an orange within an orange, the enclosed fruit having a complete rind, in which respect it differed from one previously shown by Dr. Rendle (*Proc. Linn. Soc.* 1890–91, p. 7).—Mr. Alfred O. Walker read a paper entitled "Contributions to the Malacostracan Fauna of the Mediterranean," in which he gave the results of dredging operations carried on at Cannes and Hyères from an open boat, in depths not exceeding 35 fathoms and with the simplest apparatus. The number of species obtained were as follows:—Podophthalmata, 10; Schizopoda, 8, including a new species, *Mysidopsis serraticauda*; Cumacea, 9; Pantopoda, 1; and Amphipoda, 41, including two new species, *Leucothoe platydactyla* and *Melphidipella* sp., with two others not previously recorded in the Mediterranean.—Miss G. Lister's paper on the occurrence in Egypt of *Tristicha hypnoides*, Spreng., communicated by Mr. Arthur Lister, F.R.S., was read by the secretary.

Entomological Society, March 6.—The Rev. Canon Fowler, president, in the chair. Mr. H. St. J. Donisthorpe exhibited a parasite or *Brachonid* on *Centhorhynchus sulcicollis*, bred from the galls in a turnip caused by the larva of that beetle, together with the host.—Mr. A. J. Chitty exhibited a variety of *Psylliodes cyanoptera*, Ill., the coloration of the thorax dark instead of the usual red, taken by him along with the typical form in August 1892 at Wicken Fen.—Mr. H. J. Turner exhibited a long series of *Bryophila muralis* (*glandifera*) from Dawlish. The whole were either taken on, or bred from pupæ cut out of, a single roadside wall some hundred yards long, very lofty, and facing nearly north, on which aspect, however, it was protected by higher ground. They were obtained in mid-August, with the exception of a few which emerged at intervals during September and October 1900. Generally speaking the specimens were very dark, and the series was remarkable in that it contained but a few isolated examples of the forms which are prevalent in more eastern localities like Freshwater, Eastbourne or Folkestone. The hind wings of all the specimens were dark, while in the majority the black markings of the fore wings were much intensified and increased in number, and a few specimens were largely suffused with black. A considerable number showed a dark rich green suffusion, while a large proportion were of a very deep yellow or olive colour with black markings. The yellow forms were perfectly natural, as a number emerged from the pupa exactly of that hue. Only a few showed any trace of the typical delicate

dove-colour, and it was also noteworthy that the wings had a comparatively much greater area of black scaling than the eastern forms.—On the motion of Mr. H. J. Elwes, seconded by Mr. H. Goss, it was resolved that a committee be appointed to consider the question of uniformity in nomenclature for the guidance of specialists contributing to the Victoria County Histories.—The following papers were read: Centoniidæ collected by Messrs. H. E. Andrewes and T. R. D. Bell in the Bombay Presidency, with descriptions of the new species, by Mr. O. E. Janson, and a supplementary catalogue of British Ichneumonidæ, by Mr. Claude Morley.

Mathematical Society, March 14.—Dr. Hobson, F.R.S., president, in the chair.—Prof. Elliott, F.R.S., gave an account of some algebraical identities of simple arithmetical application.—Prof. Love, F.R.S., hon. sec., gave a preliminary notice concerning the theory of stability of motion.—Papers by Prof. Burnside, F.R.S., on the composition of group characteristics, and by Mr. G. H. Hardy, on the use of Cauchy's principal values in the double limit problems of the integral calculus, were taken as read.

CAMBRIDGE.

Philosophical Society, February 18.—Sir G. G. Stokes in the chair.—On the most volatile gases of atmospheric air, by Profs. Liveing and Dewar (see p. 189, December 20, 1900, for paper on same subject read before the Royal Society).—On a method of comparing affinity-values of acids, by H. J. H. Fenton and H. O. Jones. When the hydrazone of oxalacetic acid is heated with pure water, it yields the hydrazone of pyruvic acid with evolution of carbon dioxide, but in presence of dilute acids of sufficient concentration a totally different change occurs; in this case no gas is evolved and pyrazolone carboxylic acid results. Based upon these changes, a very simple method has been devised for comparing the affinity-values of acids, and the results agree remarkably well with those obtained by the well-known methods. In order to explain the nature of the changes involved, the authors attribute the evolution of carbon dioxide to the instability of the negative ion, and they have now made further experiments in order to test this hypothesis, the results being in all cases favourable. It is further shown that it is possible by this method to compare the ionising capabilities of various solvents, and experiments have now been made with pyridine in order to throw light upon the disputed question of its behaviour in this respect.—On isomeric esters of dioxymaleic acid, by H. J. H. Fenton and J. H. Ryffel. It was shown by one of the authors on a previous occasion that the ethyl ester of dioxymaleic acid exhibits the remarkable property of becoming liquid when kept in a desiccator in presence of air, although it is relatively stable in presence of moisture or in absence of oxygen. This property has now been further investigated, and it is shown that oxidation and loss of water take place with the formation of the liquid ester of dioxytartaric acid which has the anhydrous form, *i.e.* dioxysuccinic ester. Another modification of the dioxymaleic ester has also been prepared which appears to be quite stable under the circumstances above mentioned, and it is considered probable that they represent the maleic and fumaric forms respectively.—Note on the constitution of cellulose, by H. J. H. Fenton and Miss Mildred Gostling. Certain carbohydrates, when acted upon by dry hydrogen bromide in ethereal solution at the ordinary temperature, yield an intense purple colour which was shown to be due to brom-methylpurpural. This substance has been isolated in the crystalline state, and it was further demonstrated that its production is characteristic of *ketohexoses* or of substances which give rise to these on hydrolysis. Carbohydrates of the aldose type yield none of this product. Exactly similar results have been obtained by operating in other solvents at 100°, and under the latter condition it is found that all forms of cellulose give large yields of brom-methylpurpural, and it is concluded that the results definitely indicate the existence of a ketonic nucleus in cellulose.—Some substituted ammonium compounds of the type $NR'R''R_2'''X$, by H. O. Jones. This note describes some of the compounds which have been prepared in the course of the author's work on substituted ammonium compounds in which two radicles are the same.—On the molecular weight of glycogen, by H. Jackson. The important part which glycogen plays in animal metabolism renders any experiments on its constitution interesting. The only previous attempt to determine its molecular weight was by Külz a. Bornträger, who, noting the elevation of the boiling point of water when a weighed quantity of glycogen had been dissolved in it, concluded that it had the formula $(C_6H_{10}O_5)_6$. There are many objections to the boiling point method in the case of complex carbohydrates, and so it appeared important to apply Raoult's method of the depression of the freezing point, and this is easy owing to the great solubility of glycogen in cold water. The results of a number of experiments point to glycogen having a formula between $(C_6H_{10}O_5)_{40}$ and $(C_6H_{10}O_5)_{42}$. The results are somewhat similar to those obtained by Brown and Morris (*J. C. S.* 1899) for the stable dextrin obtained by the hydrolysis of starch, and it would seem to hint that glycogen is more closely related to the dextrin than the natural starches which have much higher molecular weights.—On the condensation of formaldehyde and the formation of β-acrose, by H. Jackson. An aqueous solution of formaldehyde, obtained by boiling paraformaldehyde, was treated with basic lead carbonate and heated on a water bath for one hour. After filtering it was evaporated in vacuo at 50° and the syrup treated with a mixture of methyl and ethyl alcohols. The insoluble lead salt was separated and the alcohol distilled off from the sugar. A two per cent. aqueous solution of the sugar was heated with phenyl hydrazine acetate on the water bath for four hours. The crude osazone was boiled with water; and acrosazone (Fischer and Passmore, *Ber.* 1899) remained undissolved. The filtrate from this on cooling deposited a mass of fine yellow crystals. These were recrystallised twice again from hot water. This was found to be a mixture of osazones which have been separated by a long series of fractional precipitations.

PARIS.

Academy of Sciences, March 18.—M. Fouqué in the chair.—On the determination of latitude at sea by circum-meridian observations, by M. E. Guyou.—On the propagation of discontinuities in a viscous fluid, by M. P. Duhem.—M. Humbert was elected a member in the section of geometry, in the place of the late M. Hermite.—On the law of universal attraction, by M. H. Duport. By applying to a system of atoms the principle of least action there is obtained a generalisation of the formulæ of Mayer.—Remarks by M. Bouquet de la Grye on a work by M. P. Chevalier on the hydrography of the Upper Yang-Tse Valley.—The true value of the period of luminous variation of the planet Eros, by MM. Ch. André and M. Luizet. Two views have been put forward by astronomers who have studied this question: one representing it as a simple oscillation, always identical and reproducing itself at intervals of about 2h. 5m., the other representing the curve as being formed of two different branches, the whole of which is reproduced at intervals of about 5h. 3m. A discussion of the whole of the observed values tends to show that this latter view is the correct one, the true period being about 5h. 16m.—On the zeros of entire functions of n variables, by M. P. Cousin.—On the vibrations of beams supported at the ends, by M. Ribière.—On the entropy diagram, by M. L. Marchis. In recent years the entropy diagram has been applied by engineers to the representation of the quantities of heat given out or absorbed by the working fluid in the steam engine. In the present paper the conclusion is drawn that this application is not legitimate, and that similar difficulties arise in dealing with the gas engine.—On the propagation of discontinuities in fluids, by M. E. Jouguet.—On the action of acids upon the carbonates of the alkaline earths in presence of alcohol, by M. C. Vallée. The action of dilute sulphuric acid upon calcium carbonate is very slow in the presence of absolute alcohol, but the reaction is not a limited one, the neutralisation being complete if sufficient time is allowed.—On some cæsium compounds, by M. E. Chabrie. A description of the preparation and properties of cæsium bromide, iodide, fluoride, chromate and bichromate.—On the constituents of commercial ferrosilicons, by M. P. Lebeau. In commercial ferrosilicons three silicides are clearly made out, $SiFe_2$, SiFe and Si_2Fe, and methods are described for obtaining each of these in a pure state.—Action of the acid chlorides and anhydrides upon the organo-metallic compounds of magnesium, by MM. Tissier and Grignard. With acetyl chloride, magnesium methyl iodide gives trimethyl-carbinol, and with benzoyl chloride dimethyl-phenyl-carbinol is obtained. The anhydrides give similar products.—The action of caprylic alcohol upon its sodium derivative: synthesis of dicaprylic and tricaprylic alcohols, by M. Marcel Guerbet.—Vaporisation and hydration of ethylene-glycol, by M. de Forcrand.—Dissociation and thermal study of the compound $Al_2Cl_6, 18NH_3$, by M. E. Baud.—On direct nitration in the fatty series, by M. A. Wahl. An attempt was made to directly nitrate ethyl crotonate and tiglate,

but no true nitro-derivative could be obtained.—On the supposed binaphthylene alcohol, by M. R. Fosse. The compound described by Rousseau as a binaphthylene alcohol is a derivative of trinaphthylmethane.—On the $\beta\beta$-diacetylpropionate of ethyl, by M. F. March.—Properties of the alkyl substitution products of the ethyl ester of cyano-acetone-dicarboxylic acid. Action of cyanogen chloride upon the methyl ester of acetone-dicarboxylic acid, by M. J. Derôme.—The action of butyryl chloride upon the sodium compound of methyl acetoacetate, by MM. Bouveault and A. Bongert. Two classes of substances are produced in this reaction, there being a true carbon linkage in the one, whilst in the other the carbon atoms are joined through an oxygen atom. The separation of these isomers is described and some of their characteristic properties studied.—On the constitution of gallotannin, by M. H. Pottevin.—The production of acetyl-methyl-carbinol by the *Bacillus tartricus*, by M. L. Grimbert. By the action of this bacillus upon solutions of glucose or sugar, small quantities of the alcohol $CH_3-CO-CHOH-CH_3$ are produced. This substance, which has not been previously noted as a fermentation product, was identified by means of its osazone.—On the diagnosis of tuberculosis, by MM. Albert Robin and Maurice Binet. It is found that the respiratory exchanges are much higher in tuberculous subjects than in the healthy man, and this feature is so constant that it will be of service in the diagnosis of tuberculosis.—The slow conduction of the nerve and negative variation, by M. Aug. Charpentier.—On the opacity of the vitreous body and the rigidity of this medium of the eye, by M. A. Imbert.—On the histology of the branchia and the digestive tube, by M. P. Vignon.—On the absorption of highly diluted metallic poisons by plant cells, by M. H. Devaux. Both phanerogams and cryptogams are poisoned by solutions of lead and copper salts containing only one or two parts of the salt in ten millions of water.—Influence of darkness on the development of flowers, by M. L. Beaulaygue.—Comparative anatomy of the leaf organs in the acacias, by M. P. Ledoux.—On the tabular icebergs of the Antarctic regions, by M. Henryk Arçtowski.

CAPE TOWN.

South African Philosophical Society, February 6.—T. Stewart, vice-president, in the chair. Mr. E. H. L. Schwarz exhibited some photographs and copies of interesting Bushman paintings from Groot Riet River, near the boundary of the Ceres and Clanwilliam districts, on the road from the Cold Bokkeveld to Whupperthal. The drawings are on the face of a cliff overhanging a tributary of the Groot Riet River. There is no cave properly speaking, but the river has cut slightly into the cliff at the base, so as to form a shallow recess. The floor of the recess is some 20 feet above the present river level, and a fine Bushman pot (exhibited) was obtained here. The paintings themselves are done in a great number of styles, by different people. They are in red paint, except for three black and one brown figure. Mr. Sclater pointed out that one of the photographs evidently represented the drawing of a white rhinoceros, an animal of whose occurrence so far south no written record has been preserved.—Mr. A. W. Rogers read a paper on evidence of glacial action during the deposition of the Table Mountain sandstone.—Mr. Sclater having taken the chair, Mr. Stewart read a paper on the rainfall of the Cape Peninsula. The average for the last seven years at Signal Hill is 15·49 inches; at Rondebosch 41·22 inches; at Kenilworth 42·90 inches; at Disa Head (2500 feet above the sea) on Table Mountain 39·96 inches; and at Maclear's Beacon (3478 feet above the sea) on Table Mountain 86·81 inches. The heaviest rainfall in the Peninsula is registered at the last station. The rainfall during the month of January last was of an exceptional character, in fact there is no record of a previous rainfall during any of the summer months having approached the amount recorded.

DIARY OF SOCIETIES.

THURSDAY, MARCH 28.

ROYAL SOCIETY, at 4.30.—(1) On the Arc Spectrum of Vanadium; (2) On the Enhanced Lines visible in the Spectrum of the Chromosphere: Sir N. Lockyer, K.C.B., F.R.S., and F. E. Baxandall.—Further Observations of Nova Persei, No. 2: Sir N. Lockyer, K.C.B., F.R.S.—The Growth of Magnetism in Iron under Alternating Magnetic Force: Prof. E. Wilson.——To be read *in title only*; On the Electrical Conductivity of Air and Salt Vapours: Dr. H. A. Wilson.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—The Electrical Transmission of Power in Coal Mines: H. W. Ravenshaw.—Portable Electric Lamps: S. F. Walker.

CHEMICAL SOCIETY, at 3.—Annual General Meeting.

FRIDAY, MARCH 29.

ROYAL INSTITUTION, at 9.—Polish: Lord Rayleigh, F.R.S.

SATURDAY, MARCH 30.

ROYAL INSTITUTION, at 3.—Sound and Vibrations: Lord Rayleigh, F.R.S.

ESSEX FIELD CLUB (Essex Museum of Natural History, Stratford), at 5.—Twenty-first Annual Meeting.——At 6.30.—Neolithic Implements from the North Downs: J. P. Johnson.—On Borings of the Ash-bark Beetles (*Hylesinus*): Miller Christy.—Lantern Demonstration of Colour Photography as applied to Natural Objects: E. Sanger Shepherd.

MONDAY, APRIL 1.

SOCIETY OF CHEMICAL INDUSTRY, at 8.—The Effect on the Marsh Test of some Commercial Products containing Selenium and Tellurium: A. E. Berry.—A New System for the Manufacture of Borax and Nitrates: Dr. W. Newton.—Basic Superphosphate: its Preparation and Use as a Manure: John Hughes.—The Preparation of Pure Cineol from Eucalyptus Oil by means of the Arsenate: Watson Smith.—Action of Caustic Potash and Soda on Stannous Sulphide: Dr. F. Mollwo Perkin.

VICTORIA INSTITUTE, at 4.30.—The Maori's Place in History: J. Rutland.

TUESDAY, APRIL 2.

ZOOLOGICAL SOCIETY, at 8.30.—On the Myology of the Tongue of Parrots, with a Classification of the Order based upon the Structure of the Tongue: G. P. Mudge.—On the Structure of the Larynx in *Cogia* and *Balaenoptera*: Prof. W. B. Benham, F.R.S.—On a Collection of Lizards from the Malay Peninsula, made by Members of the "Skeat Expedition," 1899–1900: F. F. Laidlaw.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Burrator Works for the Water-supply of Plymouth: E. Sandeman.

ROYAL PHOTOGRAPHIC SOCIETY, at 8.—Animals and Birds in their Native Haunts: Charles Reid.

WEDNESDAY, APRIL 3.

GEOLOGICAL SOCIETY, at 8.

ENTOMOLOGICAL SOCIETY, at 8.

SOCIETY OF PUBLIC ANALYSTS, at 8.—On the Maumené Test for Oils: C. A. Mitchell.—Some Arsenic Estimations relating to Malt Kilns: T. Fairley.—The Aeration Test for Effluents: Dr. S. Rideal.

THURSDAY, APRIL 4.

LINNEAN SOCIETY, at 8.—On some British Freshwater Rhizopods and Heliozoa: G. S. West.

CONTENTS.

THURSDAY, APRIL 4, 1901.

SPACE, ATOMS, MOLECULES AND THE ETHER.

Matter, Ether and Motion. By A. E. Dolbear, Ph.D. English edition edited by Prof. Alfred Lodge. Pp. vii+376. (London: Society for Promoting Christian Knowledge, 1899.)

La Constitution du Monde, Dynamique des Atomes. Par Madame Clemence Royer. Pp. xxii+800. (Paris: Librairie C. Reinwald, 1900.)

Mutmassungen über das Wesen der Gravitation, der Elektricitäts und der Magnetismus. Von Dr. med. Hermann Fischer. Pp. 42. (1899.)

Ueber mögliche Bewegungen möglicher Atome. Von Dr. med. Hermann Fischer. Pp. 92. (Dresden: Hellmuth Henkler, 1900.)

A QUARTER of a century ago the Society for Promoting Christian Knowledge published a small book of 125 pages on "Matter and Motion," by Prof. Clerk Maxwell, and it is interesting to reflect that the necessity of adding the ether to the title of a new book issued by the same publishers is largely due to the important modern developments of the ideas which, in his more abstruse writings, the author of the original book suggested. There is, no doubt, a considerable demand at the present time for a book dealing in a popular way with general notions about molecules and the ether; but it is desirable that, in attempting to meet this demand, scientific accuracy no less than simple and popular treatment should be aimed at.

Dr. Dolbear is fortunate in having it stated conspicuously that his book is "edited by Prof. Lodge," who in his preface remarks that

"the luminous manner in which the author deals with the great problems as to the nature of electricity, magnetism and the kinetic relations between ether and matter will make this book interesting and instructive to a wide circle of readers."

But even the editor is bound to admit that

"I do not agree with all the author's statements, particularly that on p. 75, where he maintains that transfers of energy are always from bodies having higher rates of motion to those having lower rates. . . ."

An examination of the book shows that it contains many statements quite as open to objection as that cited by Prof. Alfred Lodge. A few extracts will give an idea of the style of the book.

On pp. 14–17 the author takes a great deal of trouble to prove that we shall never be able to construct a microscope sufficiently powerful to see individual molecules. To prove this, he tries first to argue from a rather far-fetched analogy between the powers of the microscope and the stage-coach and the railway; then he refers to the impossibility of seeing molecules owing to their rapid motions; and finally he states that

"there is every reason to believe that the molecules of all bodies are so perfectly transparent that they could no more be seen than the air, even if there were no difficulty from their smallness and their motions."

It would be more correct to refer to p. 149 and to point out that the limits of microscopic vision are defined by the wave-length of light.

On pp. 48–49, speaking of different kinds of motion, we are told:

"For instance, a compound of a free path motion with a vibratory motion will give a wave or sinuous motion if the direction of vibration be at right angles to the free path."

A little further down, on p. 49, the author says:

"Indeed, we know that some sorts of motion are propagated in the ether. For instance, what we call light is an example. Its form is *undulatory;* and as we have seen an undulatory motion is a compound of a re ctilinear and a vibratory. . . ."

While seven lines lower down he says:

"I am not aware that any simple rectilinear motion is known to occur in the ether; there may be, and likely enough is, such."

In speaking of non-Euclidean geometry, he suggests a rather curious idea of the relations between men of science of different countries:

"This new geometry I have alluded to has been worked at by the best mathematicians of all civilised nations, and they agree in their conclusions. They certainly would not do so if there were the slightest apparent reason for rejecting them; for national jealousies are too strong, and a sense of the value of truth too great, to allow any such notions to gain currency anywhere if there were any possibilities of breaking them down."

Here is how the author defines mass, on p. 61:

"It has become necessary to find some measure for matter that shall be independent of position, and this has been found by dividing the weight of a body at a given place by the value of gravity at that place and calling the quotient the mass, so that if w represents the weight of the body at a given place and g the value of gravity at the same place, that is the velocity per second that gravity will give to a body if left free to fall, then $w/g = m$, the mass."

This definition is calculated to make any reader think that the mass of a body weighing 1 lb. is 1/32·091 at the equator and 1/32·255 at the poles. How is such an inference to be reconciled with the statement that it is "independent of position"?

Further on (p. 346) we have another definition of mass:

"Mass as a property of matter is generally defined as the amount of matter considered, and is measured by what is called acceleration, that is, the velocity it acquires in a second when acted on by a constant force or push."

On p. 106 we have the following definition of temperature:

"The word 'temperature' is used to denote the degree of heat there may be in a unit volume of the substance. . . ."

According to this, calorimetry would be made easy, for (*e.g.*) a cubic foot of lead and a cubic foot of air at the same temperature should contain the same "degree of heat"! As a final sample, we quote the author's explanation of the heating of a gas by compression on p. 322:

"When a gas is condensed by pressure the individual molecules have less free space to move in, and they consequently collide with each other more frequently. Being

A A

elastic their average amplitude of vibration is increased proportionally, and a greater number of them will strike with greater velocity upon the walls of the containing vessel per second than before. Thus the temperature and the pressure of the gas are increased. We say that mechanical energy has been converted into heat energy, or sometimes simply into heat, though what has really happened has been the transformation of external translational motion into internal vibratory motion, which the elasticity and mobility of the molecules permit. When by friction or percussion a body is heated, the same thing precisely has happened; translatory motion has been transformed into vibratory, through the agency of the molecules, which have, therefore, acted as machines for transformation."

Madame Royer has produced a volume of 800 pages, in which she has endeavoured to expose fallacies in the existing theories of matter and to formulate a new theory of her own. The book is illustrated by coloured plates and pretty pictures of molecules built up of atoms. It deals in turn with the history of theories of matter, properties of atoms, vibratory phenomena (including heat, light, sound, smell and taste), solid bodies, liquids and gases, vital processes, gravity, theory of the tides and cosmic evolution.

Madame Royer seems to believe that atoms are fluids in their nature (the indivisibility of atoms has long been a thing of the past) and that there are three states of the cosmic substances, namely, the initial or ethereal state, in which the atoms are without mass and preserve the properties of perfect fluids; the material state, in which the atoms only possess a variable finite portion of their initial expansive substance and all their fluid properties are attenuated; and the vitaliferous state, in which the atoms are not subjected to the laws of inertia and gravity, but can overcome these in producing automatic movements. No such thing as attraction is supposed to exist, but the fluid atoms are held together by an ethereal pressure; they would be spherical when isolated, but when formed into molecules they become compressed into polyhedral forms. The authoress takes exception to the accepted theory that quantity of matter is synonymous with mass; but does not this mainly depend on what we define to be *matter*?

The explanation of gravity attributes this phenomenon to pulsating pressures in the ether—an idea by no means novel, the hydrodynamical theory of pulsating spheres being well known. How far Madame Royer has worked on old lines, and how far she has invented a new theory, it is not our present purpose to examine. We cannot discover anything very remarkable in her new theory of the tides, the principal point of which appears to be that it is necessary to discuss the tides in the earth and the atmosphere as well as in the sea.

It may be convenient here to state roughly in an abridged form the fundamental assumptions stated on pp. 68–70:

"(1) The primary elements of cosmic matter are volumes of fluid, which tend to expand by reason of their internal activity, but are kept from so doing by external and mutual pressures. (2) The cosmic elements constituted by centres of emission of an indefinitely expansive substance are active, and repel one another according to the law of the inverse square. (3) Ponderable bodies are constituted of elements in which the expansive forces are attenuated, and their inertia is inversely proportional to the radius of their virtual sphere. (4) The masses of ponderable bodies are equal to the sums of the inertiæ of their elements, and vary directly as their number and inversely as the cube roots of their expansive forces. (5) The variations of volume of complex bodies under changes of pressure and temperature are the result of correlative variations in volume of their elements, which remain always in contact and are bounded by planes of mutual intersection. [Is it certain that the boundaries are always plane?] (6) It follows that the universe is absolutely filled [with a medium, of course] under constant average pressure, and the local and temporary variations of pressure are the cause of all motion."

The book is evidently the outcome of many years of thought and study on the part of its writer, and it would be of little use to express a single opinion, favourable or unfavourable, on it in a review. Some of the ideas give one the idea that there is much to be said in their favour. The suggestion that what we call atoms may be represented better by portions of fluid than by solid bodies is, whether tenable or untenable, certainly worth careful consideration, and should, if new, certainly be labelled and consigned to its proper place in the storehouse of accumulated thought which is being built up under the general title of "theories of matter." But is it new?

Dr. Fischer, in his first paper, takes as his starting point Korn's theory, according to which gravitation and electricity are referred to a periodical pressure to which the whole solar system is exposed. He considers, however, that it is not necessary to go outside the solar system to find an explanation of the phenomena, but that they can be explained very well by certain ordered motions within the system itself. He assumes the existence of two kinds of atoms, namely, the atoms of chemical elements and those of the ether. The majority of element-atoms are supposed to be elongated, those of the ether being spherical, of average equal size and practically of the nature of mathematical points.

"Possible motions of possible atoms" is an inviting title for his second paper. Its sections deal with space and time, matter and force, the chemical atoms, the ether atoms, the motion of chemical atoms and molecules, and cosmogony. In summing up, Dr. Fischer arrives at the following conclusions:—(1) Discrete deformable active atoms can only be of approximately spherical shape, never with sharp corners or edges; (2) Element-atoms of the most varied forms can be built up of such discrete atoms; (3) Owing to their activity atoms can move, and every motion is due to some force acting on matter; motion is only produced by leaps or bounds, after which it remains constant in magnitude and direction, and can only increase and decrease by jerks. A curvilinear motion is to be regarded as made up of a series of elementary rectilinear motions; (4) Elastic stresses presuppose deformable active atoms; (5) After elastic repulsions, deformable active atoms of certain dimensions may either designedly come into contact or separate; (6) With regard to oscillatory motions, approximately spherical atoms move uniformly, while element-atoms and molecules, especially those of elongated form, can either be turned about their axes or they can perform elliptic or circular oscillations made up of elements of rectilinear motion in directions along, perpendicular to, or inclined to their

axes; or the parts of a molecule may oscillate about their common centre of mass; (7) All oscillations are either ordered or unordered motions.

The various types of oscillation are held by Dr. Fischer to account respectively for chemical light-vibrations, electric light-vibrations, heat, gravity, electric and magnetic phenomena.

While Madame Royer's speculations on the nature of things lead her to think that the laws of nature are never disturbed by "that imaginary being called God, who has no place in an autonomous universe," Dr. Fischer concludes his paper with the quotation

"Die Himmel erzählen des Ewigen Ehre."

We far prefer the spirit of the latter writer, who in the course of his work clearly sees that theories of matter can but be approximate mechanical representations of the truth. It is true that a good deal of progress has been made of late years in the conception of elements and media which reproduce more or less closely the physical phenomena known to us; but whether we regard the universe as filled with a single medium and atoms as singularities occurring in it, or regard everything, including the ether, as built up of discrete atoms, a reduction of the number of varieties of atoms and media is not necessarily synonymous with an advance in physical theory. What is rather wanted is to reduce to their minimum the number of fundamental hypotheses required for the mathematical deduction of the physical phenomena known to us. This was the spirit which actuated Maxwell, and while since his time we have become more and more familiar with molecules and the ether, it is doubtful whether our advances in reducing their properties to mathematical formulæ have been so great as they ought to be. With the exception of Larmor, there are few physicists now carrying on the work of Maxwell, and there is, unfortunately, a growing school who conceal their ignorance of the causes of things by referring everything to "molecules" or "the ether," and endowing these with new properties without troubling much if such properties are reconcilable with those previously attributed to them. What is equally important, as our theories of matter advance, fresh properties become known to us, so that as soon as we have climbed to the summit of one hill, we see a still higher one ahead. G. H. B.

ALLEGED HYPOSTOMIAL EYES IN THE TRILOBITES.

Researches on the Visual Organs of the Trilobites. By G. Lindström. Kg. Svn. Vet. Akad. Handlg., Stockholm. Bd. 34, No. 8. Pp. 74; 6 plates. (1901.)

THIS memoir of 74 pp., illustrated by six most beautiful plates, deals in reality with the joint labours of the author whose name appears upon the title-page and his talented assistant, G. Liljevall, to whom the first detection of the central fact of the presence of supposed eyes on the labrum (hypostome), the labour of cleaning and preparing the specimens described, and, above all, of making the original drawings (for which no praise can be too high) are due. The material described is mostly a rich collection preserved in the Swedish National Museum; but it is explained, with comment none too flattering, that "collections of foreign species and the waste (vast) European and American literature" have been taken into account. The work opens with a short introduction, dealing mainly with the detailed surface anatomy of the hypostome and the orientation of the supposed hypostomial eyes, or "maculæ," as the authors name them, together with an account of the first observations upon which, by comparison with the cephalic eyes of the compound type, they were led to regard the maculæ of the facetted kind as visual in function. There then follows a chapter upon the blind Trilobites. A detailed dissertation upon the origin and nature of the ridge hitherto designated the "eye-lobe," "ocular fillet," or "Augen Leiste," and known by a variety of other names, next follows; and the authors, finding that "in a long series of genera succeeding each other it has no connection whatever with any eye," prefer to term it the "facial ridge"; and they subdivide the blind species into series characterised by its presence or absence.

In the foregoing section much is made of the young larvæ of Olenellus, discovered by Ford and Walcott, as furnishing a clue to the development of this facial ridge, and of the fact that during the growth process of the higher forms the pygidium follows the head region in order of appearance, and that the intervening "thorax" or body-segments are intercalary in origin. Passing to detail concerning the head, Bernard's terms, "rhachis" and "pleura" are preferably employed, and in dealing with its anatomy a passing compliment is paid to the Japanese embryologist, Kishinouye. Attention is next drawn to an important series of growth stages of Liostracus, described by Brögger in 1875, but generally overlooked, and from the study of these the conclusion is reached that the developmental changes of the head segments in the higher Cambrian and Silurian forms are of a different order to those of the Olenellidæ and Paradoxidæ, which Dr. Lindström would apparently regard as representative members of distinct series; and the final result is arrived at that the earliest oculate genus was Eurycare of the Olenellus schists, and that Olenus and Parabolina were probably blind.

The succeeding section is devoted to the consideration of the eyes of the Trilobites, the detailed structure of which the authors, with immense labour, have investigated, by sections taken at various planes and by other means at their disposal. They have been thus enabled to distinguish four types of cephalic eye, which they believe to have probably succeeded one another in the following order, viz. the simplest or Harpes type, of simple ocelli; the Eurycarid, biconvex or lentiform type; the Megalaspid or prismatic type; and the Phacopsid or "aggregate" type—each of which is duly figured with as much detail as is forthcoming, and in section as observed for thirty-six species. Further detail under this head is impossible in these pages; and we pass at once to the fuller consideration of the "maculæ," or hypostomial eyes so-called.

Although the authors record these organs for some 136 species of thirty-nine genera, they state at the outset that the genera in which they have found them lens-bearing are relatively few, and that the lenses or "granules," even where recognisable, have been found to be present only

over the lower third of the macula, with the exception of the Asaphidæ, Illænus and Lichas, of which they remark the entire macula shows "the structure which characterises" it as a visual organ. Beyond this, the macula, for which an average diameter of 0·99 mm. is given, is described as "oblong or ellipsoidal, and for two-thirds of its surface perfectly smooth or rather glossy," and its "granules" or lenses are estimated to be but 0·055 mm. in diameter at their largest.

With the maculæ, as with the cephalic eyes, a wide range of modification is recognisable, which, if the authors' assumption of a visual function for the former be correct, leaves little doubt that the facetted type is for it a culminating one. They state that the maculæ, "whether they show any organic structure or not," have commonly an "excessive thinness of their shell," and in so far as they enter into comparison with other Crustacea, while they call attention to the similarity "in the formation of the superior surface of the head in the Trilobites and the embryos and newly-hatched larvæ of Limulus," they incline to the belief that, concerning the cephalic eyes, Limulus "stands completely isolated amongst all Arthropods," except for a certain resemblance between its cornea and that of Peltura." They similarly deny resemblance to the Phyllopods, and regard "the eyes of the Trilobites" as showing "the greatest conformity with those of the recent Isopods."

Full perusal of the details which they attribute to the hypostomial macula shows them to have discovered an interesting and important organ. Comparison is instituted between it and a thin area of the hypostome of the living Apus; but, if sound, there is not much to be said from this standpoint for the "eye" theory in any but the facetted forms. For the types which remain, the study of the remarkable details described in the memoir leaves us in doubt as to the evidence for the supposed visual function. Convinced of its actuality, however, in an attempt to bring the living Crustacea into line, the authors fall back upon the fact that in the embryo Limulus the median eyes have been described by Packard and others as originally ventral, and that there have been recorded for the Lepadidæ two ventro-lateral eyes in an adult by Darwin, two ventro-lateral and a ventro-median one in a larva by Claparede, and similar indications by Hesse and Spence Bate.

Remarking upon the supposed habits of the Trilobites, of which we know nothing very definite beyond that a burrowing habit has been suggested, our authors express themselves averse to the popular idea that they "lived in abyssal depths . . . where the most intensive darkness prevailed." There are, however, considerations arising out of recent discovery concerning these animals worthy of note in this association. Owing to the wonderful conditions for preservation which characterise the Utica slate deposits near Rome, N.Y., certain Trilobites, during the last six to seven years there unearthed, as all zoologists are well aware, in the hands of Dr. Beecher, of Yale College, Conn., have yielded results of importance second to none in the palæontology of the period. The proof that but one pair of antennæ were alone present, and that they were uniramous, brings the adult Triarthrus at once into line with the Nauplius larva, as distinct from all other known Crustacean forms; while that of a simple uniformly jointed condition of the post-oral appendages, most, at least, of which were biramous, and of the Phyllopodan tendency of those posterior and last developed, more than fulfils the highest expectations of the philosophic morphologist, and amply justifies our trust in the larval form. One conspicuous feature of these appendages is the recurrent development from each of an inwardly directed and tapering gnathobase, most assuredly concerned with its fellows in the seizure of the prey and, by transfer of this from limb to limb, with its passage to the mouth. We know nothing of the habits of these animals as they swam, but from this feature the possibility is suggested that, like the living Apus, they may have swum upon their backs; and, if so, the presence of hypostomial eyes would become the more readily intelligible. On the other hand, the possibility that the "maculæ" may have been luminous organs must not be overlooked; and bearing upon this surmise, it is well to remember that such organs are known to exist in a lenticulate and aggregated form, and that the probable presence of one of simple type in a sponge, taken in conjunction with the extent to which like organs are functional as a lure to the prey, would dispose of any anomaly in their possession by blind animals. And finally, inasmuch as the remarkable organs present in the Chitons, some of which, being lens-bearing, were by Moseley described as eyes, so far as experiment with light has yet progressed, have given but negative results, it becomes a question whether, until we know more concerning even these, the term "æsthete" may not be well extended to them all. Arguing by analogy from these to the Trilobite "maculæ," it must be admitted that their visual function is not proved.

In the further inquiry into the nature of these remarkable organs there lies a most promising field. As we cannot experiment with them, we provisionally retain an open mind concerning their functions; and while we are profoundly grateful to our authors for their intensely interesting memoir and the great labour they have bestowed upon it, we shall await with much interest the further results of their inquiry.

G. B. H.

THE RELATIONS OF THE OSTRICH-LIKE BIRDS.

On the Morphology and Phylogeny of the Palaeognathae (Ratitae and Crypturi) and Neognathae (Carinatae). By W. P. Pycraft. *Trans.* Zool. Soc. London, vol. xv. pp. 149–290, pls. xlii–xlv.

THE relation of the flightless ostrich-like birds (Mr. Pycraft says we must no longer call them Ratitæ) to more typical representatives of the class Aves has long been one of the puzzles of ornithology, and it is therefore a matter for satisfaction that the author of this important memoir has undertaken the task of revising and extending our knowledge of the anatomy of the existing members of the former group. The work was undertaken in connection with Mr. Walter Rothschild's revision of the cassowaries, of which, indeed, it forms the sequel; and the thorough manner in which it has been carried out forms a model of what such researches should be, and enables zoologists to draw their own conclusions on the questions at issue, if they are unable to accept all those at which the author arrives.

For a long time ornithologists have been hesitating whether or no to include the tinamus of South America in the same group as the ostrich-like birds; but this hesitating spirit does not commend itself to Mr. Pycraft, who boldly says that the affinities between the two imperatively forbid their separation. And it is this innovation which leads him to reject the time-honoured title, Ratitæ.

The inclusion of the tinamus in the group renders it necessary to assume (even if we had not to do so on other grounds) that the ancestors of the ostrich and its kindred were formerly endowed with the power of flight. Further, the author regards the group as a convergent one, which has had a multiple origin from the common avian stem before this began to split up into the more specialised "Carinate" types. The cassowaries and emeus are regarded as representing the most primitive branch, which culminated, perhaps, in the more advanced ostrich. From this it apparently follows, although it is not stated in so many words by the author, that the divergence of the Ratites (to call them by their old name), including the tinamus, took place while birds still retained teeth. While this may be so, it must be confessed that some palæontological evidence in its favour would be most welcome.

It may be added that, according to the genealogical tree given by Mr. Pycraft, the loss of the teeth in birds must have taken place at a still later epoch, for we find the cretaceous Ichthyornis branching off long after the divers and ducks had been differentiated. This seemingly implies that the origin of the latter is to be carried back to the Jurassic epoch, when, so far as we yet know, Archæopteryx was the sole representative of bird life. The author promises a supplementary memoir on Apteryx, where he will, perhaps, explain how we are to get out of this difficulty.

A slight discrepancy between the aforesaid "tree" and the text likewise stands in need of explanation. On p. 264 of the latter it is stated that the ostrich-like birds "are to be regarded as polyphyletic—probably triphyletic," and yet in the "tree" we find them arising from five distinct branches.

Space does not allow of allusion to the many interesting observations on the osteology and pterylosis of the group recorded by Mr. Pycraft, but these really form a storehouse of information of the utmost value to future workers. As he himself would doubtless be one of the first to allow, opinions may legitimately differ in regard to many of the conclusions arrived at by the author, but as to the value of his investigations all opinion must be in accord. R. L.

OUR BOOK SHELF.

Researches on the Past and Present History of the Earth's Atmosphere. By Dr. T. L. Phipson. Pp. xii + 194. (London: Charles Griffin and Co., Ltd., 1901.)

IN style and scope, Dr. Phipson's book reminds us of essays submitted to the Smithsonian Institution for the Hodgkins Fund Prize, and afterwards published in the Smithsonian Report. A more or less popular description is given of the atmosphere in its various relationships to man, and in its meteorological aspects; while in many places short statements are made of observations and investigations carried out by the author himself. The book should thus prove of interest to general readers as well as to meteorologists and other students of science.

In the early chapters, the thesis which Dr. Phipson seeks to establish is "that the primitive atmosphere of the earth was nitrogen, into which volcanic action poured more or less carbonic acid and vapour, and that after vegetable life appeared, free oxygen made its appearance in the air, and has increased in quantity from those primitive times to the present day." In connection with the subject of the variations in the amount of carbon dioxide in the air, it might have been well to refer to the work of Arrhenius, Chamberlin and others on the effect of variations in the proportion of the gas in air upon the mean annual temperature, and past geological conditions.

Dr. Phipson regards argon as allotropic nitrogen or a carbide of nitrogen. The hydrogen gas driven off from meteorites when heated is, he holds, produced by the decomposition of water vapour by the meteorite during the passage through the air, or the absorption of water, the oxygen of which combines with some of the constituents of the meteorite when it is heated, thus setting hydrogen free. He refers to the variation in brightness of the star Algol as "still a mystery to astronomers," though the spectroscopic work of Vogel has placed the cause of variability almost beyond doubt. Like many other writers who have not followed closely the physical geography of recent years, Dr. Phipson believes in the Gulf Stream myth, going so far as to commit himself to the statement that "The mild climate of the British Isles is very greatly due to this immense current of warm water, without which we should be no better off, in this respect, than people who live in the Arctic circle." To understand how unfounded this statement is, we refer the author to a paper in the U.S. *Monthly Weather Review* of September 1900.

In a short chapter on meteorites the remark is made, "They are, no doubt, of the same composition as the moon; and are, I believe, minute satellites of our earth, thrown off like our larger satellite was thrown off, in the earliest stages of its existence." Here again we have statements with little evidence to support them. Nothing is known of the exact composition of the moon, so the words "no doubt" in the sentence quoted are, to say the least, gratuitous.

While, therefore, we think the book contains an interesting account of the earth's atmosphere, we suggest that in several places statements are made as if they were accepted conclusions, whereas they are often opposed to the opinions of competent authorities.

Catalogue of the Mesozoic Plants in the Department of Geology, British Museum (Natural History). The Jurassic Flora. I. The Yorkshire Coast. By A. C. Seward, F.R.S. Pp. xii + 341; plates xxi. (London: British Museum (Natural History), 1900.)

FOSSIL plants from Gristhorpe Bay and neighbouring parts of the Yorkshire coast are so widely distributed among museum collections that Mr. Seward's descriptive catalogue of them will be welcomed by many museum curators in Britain and on the continent. But the volume is more than a catalogue; it is a history of Oolitic plant-remains of Yorkshire, exemplified by the fine series preserved in the British Museum. In addition to the data provided by this material, the descriptions are based upon specimens in many other collections which have been examined and considered. As might have been expected, the identification of type-specimens was a difficult task, and in many cases it has been found impossible to specify the type, which fact, remarks Mr. Seward, "has afforded a practical demonstration of the need of some system for the centralisation and cataloguing of all specimens which have served for the diagnosis or illustration of new species."

In an introduction a brief historical survey is given of our knowledge of the Jurassic plants of Yorkshire, and also of the Jurassic plant-bearing strata of France, Germany and other countries which resemble those of the Yorkshire coast.

In the descriptive part of the catalogue the specimens are grouped, so far as possible, in accordance with their natural affinities. Fifty-five species are described, and are distributed as follows:—Bryophyta, 1; Equisetales, 2; Filices, 20; Cycadales, 23; Coniferæ, 9. There is a resemblance between this flora and the Wealden flora, among the common characteristics being the absence of Angiosperms and abundance of Cycads and Ferns.

In conclusion, Mr. Seward remarks: "It is in the southern tropics that we must look for existing forms which afford the most striking links between the vegetation of to-day and that which has left imperfect records in the Jurassic sediments of the Yorkshire coast. The climate was presumably more tropical than that of North Europe at the present day; there is no evidence that the plants of Jurassic times grew under conditions which induced xerophytic characters, moisture being probably abundant and favourable to the luxuriant growth of Equisetums and Ferns."

Practical Electrical Testing in Physics and Electrical Engineering. By G. D. A. Parr. Pp. vi + 392. (London: Longmans and Co., 1901.) Price 8*s.* 6*d.*

Mr. Parr is head of the electrical engineering department of Yorkshire College, Leeds, and the book before us represents the instructions and experiments given to students in the practical course in that department. It is not our object to criticise that course, the value of which must largely depend on the theoretical teaching accompanying it; suffice it to say that it is apparently modelled very closely on that given by Prof. Ayrton at the Central Technical College. Whether there is sufficient justification for the publication of Mr. Parr's book must depend on whether the details of the system and apparatus are sufficiently widespread; in the majority of cases the instructions given for each experiment imply the provision of special apparatus for carrying out the test, and the instructions are given, if we may use the phrase, in terms of that apparatus. A more general description of the experiments would be of wider use, though probably not so convenient for the student actually passing through Mr. Parr's course. There is a good appendix describing the chief instruments and apparatus used, and another appendix giving solutions of the various problems raised by the experiments which we do not think so valuable, except as a labour-saving device to the demonstrator or idle student. The experiments are, on the whole, well devised to bring out clearly the fundamental laws of electricity and magnetism. We are sorry, however, to see included an experiment to "prove" Ohm's law, in which P.D. is measured by a high-resistance galvanometer; a galvanometer can only be employed to measure P.D. if Ohm's law be true, so that it cannot logically be used for this purpose in an experiment to prove the law. The method given second by Mr. Parr, in which an electrometer is used to measure P.D., is the only satisfactory one for proving Ohm's law. Technical teachers who are seeking to develop a practical course will find this volume a valuable guide.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* Nature. *No notice is taken of anonymous communications.*]

Audibility of the Sound of Firing on February 1.

It is an interesting question how far the accounts of various observers as to the sound of the minute guns on February 1 having been distinctly heard at many distant stations and not heard at others comparatively near by attentive listeners, and as to the character and duration of the sound, can be explained by known laws of the propagation of sound in the atmosphere. To this question I should like here to offer such answer as I have been able to arrive at after careful consideration and some rough calculation.

The firing line extended from the *Majestic* at the eastern end to the *Alexandra* at the western, in a direction some 6° N. of W. for about 8 miles. The eastern half was a double line of 16 pairs of ships, the distance between the two lines being about ¼ mile, nearly the same as that between the successive ships in each line (2½ cables or ¼ sea mile); while the western half was a single line of 14 ships.

Some stress has been laid by observers near the firing line on the want of simultaneity in the discharges from the different ships. There is doubtless need of more accurate information on this point, but I cannot help thinking Mr. Hinks's estimate that, as "the firing ran down the double line, the interval between the successive pairs of flashes was about half a second," is excessive. This would add, to an observer at Southsea, 8 seconds over and above the 19 to 20 seconds by which the sound of the westernmost pair of the double line was necessarily behind

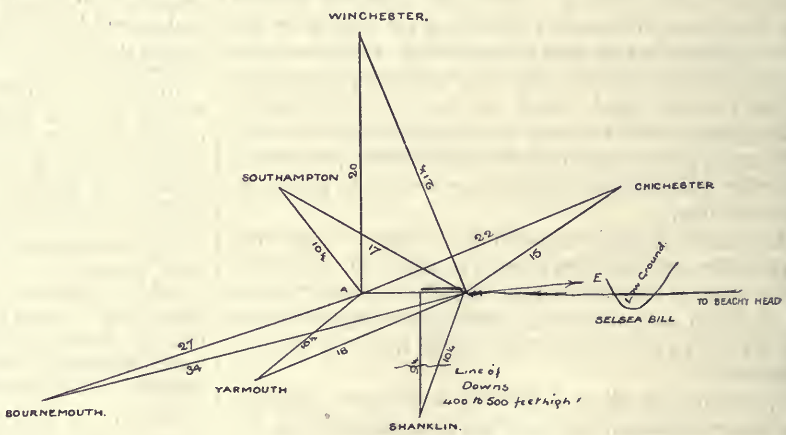

Fig. 1.

that of the first pair, whereas he says that the whole sound "lasted only about 20 seconds." I do not think, therefore, in the absence of more exact information, account need be taken in a general explanation of the supposed want of simultaneity, which I estimated on such information as I could get as not amounting to a difference of more than 2 or 3 seconds.

Mr. Hinks's observation is in another respect important, as it would seem to show that the second half of the firing line was unheard at the distance of 4 to 5 miles from its eastern end.

The known causes which would or might affect the audibility of the sound impulses arriving at any station are, I think, these: the position of the station relatively to the firing line, the direction of the wind and the variation in its speed with the height above the earth's surface, the variation in temperature of the different strata of the atmosphere, and for greater distances the curvature of the earth's surface.

Of these, for distances not exceeding 30 to 35 miles from the firing line, I believe the dominant factor to be the first, that is, relative position of the station.

The accompanying diagram (Fig. 1), drawn roughly to scale, shows this, I think, conclusively.

At Shanklin the reports were heard, but they were not very

loud or at all comparable with such as are heard there (and felt too) when gunnery practice with big guns is going on near Portsmouth. This is what might have been expected, since the nearest distance from the firing line was $9\frac{1}{2}$ miles from a point close to the west end of the double line of ships, and the distance from its extremities about $10\frac{1}{4}$ miles. Hence the sound impulses from the whole line arrived within the interval required by sound to travel $\frac{3}{4}$ of a mile, or about $3\frac{1}{2}$ seconds, and thus concentrated were audible, although a line of downs 400 to 500 feet high intervened at a distance from Shanklin of about 4 miles.

At Yarmouth a gentleman, who went on to the pier specially to listen, heard "not a single gun." This is explained by the fact that he was so near the prolongation of the firing line westward that, though only $10\frac{1}{2}$ miles from the western end, he was 18 miles from the eastern extremity, and so the sound impulses, spread over an interval corresponding to $7\frac{1}{2}$ miles, or about 36 seconds, must have arrived at intervals of a little more than a second as separate sounds from the successive ships, each by itself too feeble to be audible.

The same explanation holds for Bournemouth west and a little south of the prolongation, and for Chichester east and a little north of the same, where the sounds were not heard, the impulses being spread over an interval of about $33\frac{1}{2}$ seconds.

Winchester is 20 miles nearly due north from the western end of the firing line, and its distance from the eastern end is about $21\frac{1}{2}$ miles. The difference of $1\frac{1}{2}$ miles corresponding to about 7 seconds might perhaps have been expected to have produced sufficient concentration to make the reports audible, but they were not heard, and probably this is partly due to the intervention of the downs at the foot of which Winchester lies.

As to Southampton I have no information, but as it corresponds in position to the N. of the line almost exactly to Yarmouth on the S., there can be little doubt but that there too the firing was inaudible.

Thus far an explanation founded on the supposition of a still atmosphere of uniform temperature appears to be sufficient. But we have good evidence of the reports having been distinctly heard at distances of sixty, seventy, and even to seventy-five miles from Portsmouth in directions varying, from the eastern prolongation of the firing line, northwards through north-east to due north; but, so far as I know, not west of the north line. For these, at any rate for stations not far from the prolongation of the firing line, some totally different explanation must be found, and the first step must be to consider the effect of the wind.

Prof. Sir G. Stokes first pointed out in 1857 that, if the speed of the wind increases with the height above the earth's surface, the path of a sound ray cannot be straight, but must be curved and bent *downwards* towards the surface for rays *in the direction* of the wind, but *upwards against* the wind.

Now on February 1 there was a steady gentle wind, estimated at somewhere about five miles an hour, from the west with a cloudless sky, and no *visible* irregularities of cloud or fog to interfere with the normal propagation of sound. Hence for places west of the firing line the sound rays, on Stokes's principle, were diverted upwards into the upper atmosphere, and so passed over the heads of places at even moderate distances, so that no sound reached them. For places east of the same the contrary effect was produced, and closer examination is necessary to trace the consequences.

Proceeding from Stokes's principle, it is shown in Lord Rayleigh's "Treatise on Sound," ch. xiv., that on the hypothesis of the speed of the wind increasing upwards from the surface in direct proportion to the height, the path of a ray of sound advancing with the wind would be a catenary whose axis is vertical and directed downwards from its vertex, so that the ray, after ascending in its curved path to the vertex, would descend in a similar path again to the horizontal line through the point whence it started. Thus a ray starting from A (Fig. 2) in the direction AT would reach B in the horizontal line through A by the path ACB of the catenary, whose vertex is C, midway between A and B; and hence all the sound energy, which in air with no differential motion of its strata would have been spread over the circular sector TAB, must be concentrated between the curve ACB and the horizontal base AB. Now the angle TAB, when not large, is very nearly proportional to the distance AB, and hence in a vertical plane the concentration of the energy is proportional to the distance AB. On the other hand, in the horizontal plane the energy is spread out in azimuth proportionally to the distance AB, and thus the concentration in the vertical plane is balanced by the spread in the horizontal plane, so that the sound energy reaching two observers at different distances from A in the horizontal line AB would be about the same in amount.

There is, however, this difference, that, as the distance AB is greater, the difference in length between the curved path ACB and the direct line AB is greater, and this produces a greater retardation in time between the extreme curved ray and the horizontal ray, so that, the same energy being received in a longer time, the impression on the ear at a distant station would be enfeebled as compared with a nearer one.

Assuming this general reasoning to be correct, I have endeavoured to apply it quantitatively to the case of Eastbourne, or rather Beachy Head, for which we have the valuable observations of your correspondent, "H. D. G."

The firing line extended eastward passes directly to Beachy Head over a sea surface, with the exception of about two miles across the low peninsula of Selsea Bill. I have assumed the direction of the wind to coincide with this line, as it approximately did, and, farther, in the absence of definite data as to the rate at which the wind speed increased upwards, I have assumed it to amount to five miles per second for each mile of vertical height. I find then that at the distance of sixty miles from any firing point, which is about the distance of Beachy Head from Spithead, all sound rays starting at a less elevation above the horizon than about 11° 23′ would be bent round to the horizon between these two points, the extreme ray having reached an elevation of just over three miles; and the length of its path exceeding the direct horizontal distance by about four-tenths of a mile, it follows, from the known speed of sound, that the sound energy from a single gun would be at Beachy Head spread over an interval of very nearly two seconds. I conclude, therefore, that no single gun or pair of guns could have

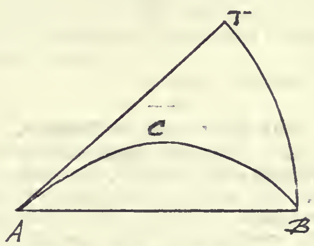

FIG. 2.

been heard there. But since the interval along the line between successive ships or pairs of ships corresponds only to a sound interval of just over one second, the sound impulses from successive ships would overlap (as they would not do at smaller distances, such as Chichester), and might so reinforce one another as to become audible. Doubtless the reflections of rays from the smooth sea surface would also contribute to this result.

Of course, the assumed data are too hypothetical for any dependence to be paid to these figures as exact results, but I think they suffice to show that the observations of "H. D. G." may thus be fairly accounted for.

His description of the sound heard as "er-er-pup-pup" would correspond with the general roll and the explosion from a pair of guns in the double line not fired exactly simultaneously, while the duration which he notes of about eleven seconds for the whole sound would correspond fairly well with the interval, some eighteen seconds, by which the sound from the last ships of the double line would be behind that from the first, and would seem to prove that the sounds from the single line farther westward were inaudible.

It is well known that the speed of sound in air does not depend directly on the density, but is affected by temperature, so that in an atmosphere of varying temperature the course of a ray must be curved. In the normal condition it is stated that the fall of temperature is about 1° C. in 330 feet of vertical height, and the consequence is that every ray of sound must be deflected *upwards*, and so at a little distance from the source would pass to the upper regions of the atmosphere over the heads of observers on the same horizontal line. This effect is probably small compared with that due to the wind. It would add to the upward bending effect for rays proceeding against the wind (in our case

westward), and somewhat flatten the curved paths with the wind; but it would not probably affect materially the general explanation above.

"H. D. G." truly observes that, owing to the curvature of the earth, his station was nearly 2000 feet below the horizontal line of Spithead, but this also would not materially alter our explanation.

So far for the sound heard at distant stations not very far from the east-west line from Spithead. When, however, we come to consider the case of Oxford and other places nearly due north, where the sound was heard, and in particular the duration of continuous sound (20 seconds) and succession of sounds and silences noted by Sir W. J. Herschel, our explanation entirely fails. It is true that the differences of distance from Oxford to the different ships were so small that the impulses from all the forty-six ships must have arrived within the interval of about half a second, but they would have diminished in intensity (according to the law of the inverse square of the distance, which in the absence of wind in their direction must be assumed) so as to be less strong than the impulse from a single gun at the distance of ten miles, a distance at which, we have seen, it would have been inaudible.

Was there a southerly current in the upper atmosphere between the Solent and Oxford? Or was the state of the atmosphere abnormal as to temperature, so that the upper regions were warmer than the lower, as hardly seems probable? Or, lastly, were the sounds heard by Sir W. J. Herschel diffraction effects outside the upward curving sound rays, as the intervals of sound and silence seem to suggest? Or is any other explanation possible from known laws?

Possibly some light may be thrown on these questions by other correspondents, or such experts as Sir G. Stokes, Lord Rayleigh or Prof. Osborne Reynolds.

The Cherbourg Peninsula at its northern end is about the same distance to the south of Spithead as Oxford to the north. It would be interesting to know if the sounds were heard by ships in the channel between the Isle of Wight and Cherbourg.

Ashcombe, Shanklin, March 12.

The New Star in Perseus.

In sending you a provisional light-curve of Dr. Anderson's new star for publication in Nature, my principal purpose has been to ascertain the nature of the curious fluctuations in the latter part of its course. I have no doubt that they are real, as even the slight irregularity in the descending curve, about March 5, has been independently detected in Leyden, and probably elsewhere also; but the periodicity that seems to establish itself in the past six or seven days may be only apparent. In this country the weather has been generally unfavourable for some weeks, and it is possible that astronomers in other parts of the world will be able to fill the gaps between the observed parts of the descending curve (on February 25, March 1, 3, 5, 6, 13, 17, 20, 21, 22, 23, 25, 27).

This star is remarkable in still another respect. It is a well-known fact that new stars have almost exclusively made their appearance in the Milky Way; moreover, it has been pointed out recently by Sir Norman Lockyer in this journal that the Novæ are not equally distributed along the galactic zone; like the "Wolf-Rayet" stars, they seem to avoid the region comprised between Cassiopeia and Carina. Nova Persei 1901 is no exception to the general rule, it being situated on a feeble distance of the central plane of the Milky Way, but as in the case with the other new star discovered by Dr. Anderson, in Auriga, it lies in a relatively poor region of the galactic zone, in which phenomena of this kind have but rarely occurred. Notwithstanding this, I think that the tendency among the new stars to group themselves in the opposite region of the Milky Way holds good as a rule.

C. Easton.

Rotterdam, March 27.

NOVA PERSEI.

The observations of the new star in Perseus have not decreased in interest since they were last referred to in Nature. Strictly according to precedent a nebular spectrum, somewhat similar to that observed by Gothard in Nova Aurigæ, followed the disappearance of the dark lines in the spectrum; but about the same time a new phenomenon in relation to Nova was observed; the star behaved like a "collision-variable."

Sudden changes of magnitude have been one of the most interesting features of this new star. Since the time (February 23) that the Nova attained its greatest brilliancy, the star gradually diminished in brightness, decreasing rather rapidly till the 13th March, and somewhat more slowly up to the 17th. Since this date periodical variations have occurred, the star decreasing to a 5·5 magnitude star and rising to about 4·2 in a period of three days (about). Thus minima were observed on March 19, 22, 25 and 28. On the evenings of the 30th, 31st and April 1 the star was of mag. 4·2, 4·3, 4·4, so that either another minimum had occurred between the times at which these observations were made or the periodicity is undergoing a change. It is important, therefore, that the light of the Nova should be observed as often as possible, so that such changes may be accurately determined.

Whether this result is due to the complete capture of the denser swarm or to other changes brought about in the sparser one, it is as yet impossible to say.

We append some extracts from a paper communicated to the Royal Society by Sir Norman Lockyer last Thursday.

Colour.—The colour has undergone some distinct changes since the observation on March 5 last, when it was shining with a claret-red hue. On the 9th and 10th it was observed to be much redder, due probably to the great development of the red C line of hydrogen.

On the 23rd and 24th the star was noted as yellowish-red, while on the 25th (after the sudden drop in magnitude) it was very red with perhaps a yellow tinge.

Since that date the star has again become much less red than formerly, and on April 1 was distinctly yellow with a reddish tinge.

The Visual Spectrum.—Since March 5 the spectrum has become much fainter, the bright lines of hydrogen being relatively more prominent than they were before; indeed, C and F throughout this period have been the most conspicuous lines, especially the former, while the bright lines $\lambda\lambda$ 5169, 5018 and 4924, and the line in the yellow at or near D, were the most prominent of the others.

All these lines have been gradually becoming weaker, but there is an indication that λ 5018 has been brightening relatively to λ 5169.

Accompanying the great diminution in the light of the Nova observed on the evening of the 25th, the spectrum was found to have undergone a great change: the continuous spectrum had practically disappeared, and a line near D (probably helium D^3) became more distinct. The other lines were hardly visible.

The Photographic Spectrum.—The spectral changes recorded in the photograph in one part of the spectrum follow suit with those observed visually in the other.

On March 6 the photograph was very similar to those obtained in the earlier stages, the only apparent difference being in the relative intensity of the bright hydrogen lines as opposed to those having other origins, most of which have been shown to be probably due to iron and calcium. The hydrogen lines have sensibly brightened, while the others have become much feebler.

The photograph of March 10 shows a further dimming of the bright lines other than those of hydrogen.

On March 25, when the next good photograph was taken, the spectrum had undergone great modifications. The hydrogen lines are still very bright, though they do not show the structure which they did in the photographs taken between February 25 and March 10. The bright lines other than those of hydrogen which are seen in the earlier photographs have now disappeared and other lines become visible. The continuous spectrum has also greatly diminished.

Rough determinations of the wave-length of these new lines have been made by Mr. Baxandall by interpolation between the hydrogen lines. They are as follows:—

387. Broad and merging into Hζ (3889).
436. Faint.
447. Not very strong. Probably Helium (λ4471·6).

456. Faint.

464. Very strong broad line. Possibly the 465 line of the bright-line stars.

468. Moderately strong. Possibly new hydrogen (λ 4686) seen in bright line stars.

471. Weak. Probably helium (λ 4713).

The hydrogen lines in the spectra are $H\zeta$, $H\epsilon$, $H\delta$, $H\gamma$ and $H\beta$.

The lines at λ 370 and 464 are perhaps identical with those observed by von Gothard[1] in the spectrum of Nova Aurigæ, after it had become nebular, but associated with these lines in his record there is the chief nebular line at 5006, no trace of which is yet visible in the spectrum of Nova Persei. On the other hand, $H\beta$, which is the brightest line in the present spectrum of Nova Persei, does not appear at all in von Gothard's spectrum of Nova Aurigæ.

Characteristics of the Hydrogen Lines.—A detailed examination of the lines as photographed on several evenings shows that their structure has been undergoing changes. On February 25 there were three points of maximum luminosity on the F line, the two maxima on the blue side being of equal intensity and greater than the third on the red side. By March 1 the centre one had greatly been reduced in magnitude, and on the 3rd it had been broken up into two portions, thus making four distinct maxima.

Rough measures made on the relative positions of these points of maxima show that the difference of velocity indicated between the two external maxima is nearly 1000 miles per second, while that between the two inner maxima is 200 per second. We thus have indications of possible rotations or spiral movements of two distinct sets of particles travelling with velocities of 500 and 100 miles per second.

A similar examination of the F and G lines of hydrogen in the photographs obtained with the 30-inch reflector has also been made by Dr. Lockyer. In this longer series the most important fact comes out that the change of maximum intensity changes from the more to the less refrangible side of the bright hydrogen line,[2] and the narrowing of the bright maximum in the middle.

So far as the observations have gone they strongly support, in my opinion, the view I put forward in 1877, that new stars are produced by the clash of meteor swarms. I have suggested some further tests of its validity.

We may hope, since observations were made at Harvard and Potsdam very near the epoch of maximum brilliancy, that a subsequent complete discussion of the results obtained will very largely increase our knowledge. The interesting question arises whether we may not regard the changes in spectra as indicating that the very violent intrusion of the denser swarm has been followed by its dissipation, and that its passage has produced movements in the sparser swarm which may eventuate in a subsequent condensation.

THE BEER POISONING EPIDEMIC.

THERE is now a pause in the literature of the most interesting, but at the same time most disastrous, beer poisoning epidemic, and the present seems a fitting opportunity to summarise the chief facts ascertained with regard to it, the deductions to be drawn from them, and, last but not least, the lessons which they teach so far as concerns the prevention of a recurrence of the calamity.

The first fact of transcendental importance was ascertained by Dr. Reynolds, namely, that the beer consumed by these unhappy individuals contained arsenic in such an amount as undoubtedly in many cases to account for the symptoms from which they suffered. So far as subsequent workers are concerned, their results have amply confirmed this fact, and there can be no doubt that the majority of patients in Manchester suffered from what has always been called arsenical poisoning. The next step was directed to ascertain how the arsenic got into the beer. Of this, fortunately, there can be no doubt it came into the beer from the sugar, and it got into the sugar through the sulphuric acid used either directly or indirectly in the manufacture of the invert sugar or the glucose. It is beside our purpose here to discuss whether all the cases of poisoning were due to the use of sugar made from sulphuric acid supplied either by one firm or prepared from one variety of pyrites. This, although a matter of paramount importance, is not essentially a matter for the man of science to decide. A definite answer to this question can only be obtained by the careful sifting of evidence, the examination of the books of various firms, &c., and is, indeed, a matter for the lawyer rather than for the chemist or pharmacologist. There can be no doubt, however, that the majority of cases observed could be traced to the consumption of beer and stout in the preparation of which sulphuric acid, supplied since the spring by one firm, had been used.

The next actual fact with regard to the causation of the epidemic was, unfortunately, discovered too late to allow of its full significance being thoroughly worked out. Two full months after the consumption of arsenicated beer had ceased, Dr. Tunnicliffe and Dr. Rosenheim demonstrated the presence in relatively large quantities (0·3 per cent.) of selenious acid in the sulphuric acid which was used in the preparation of the invert sugar supplied by the firm implicated in the recent epidemic. These observers subsequently further demonstrated the presence of this substance, which was, indeed, from their earlier work *a priori* almost certain, in the invert sugar itself and also in two different samples of beer identical with that consumed by the poisoned patients in Salford. They also pointed out at the same time that this substance is highly poisonous, certainly as, if not more, poisonous than arsenic, giving rise to symptoms almost identical with this latter poison. Exact quantitative estimations of the amount of selenium in the beer are, so far as we are aware, not yet published, but reckoning from the acid and the sugar we may calculate that this substance was present to the extent of about one quarter the amount of the arsenic present. It follows, then, that the beer consumed in the recent epidemic contained at least two poisonous substances, viz., arsenic and selenium, both of which got into the beer from the sulphuric acid used in the preparation of the sugar.

So far as concerns the actual ætiology of the epidemic, the above are all the facts which we have at present in our possession. Incidentally, however, numerous other points of extreme interest to the physician, the pharmacologist and toxicologist have arisen in the course of the inquiry.

So far as the pharmacology of arsenic is concerned, it is greatly to be regretted that our information concerning the exact amount of arsenic consumed by the individual patients is so inaccurate. This inaccuracy arises from two conditions. Firstly, it has not been in all cases absolutely established that the beer quantitatively examined for arsenic, although coming from the same source as, was identical with that consumed by the respective patients; secondly, the actual amount of beer taken by each patient was in many cases an unknown quantity. The largest amount of arsenious acid found in beer during the epidemic was 1·4 grains per gallon. Some of the sufferers undoubtedly consumed more than a gallon of beer per diem; some, however, did not consume more than a pint. This would mean that, although the former received a highly poisonous dose of arsenic, the latter would do so only in the cases of the very highly arsenicated beers, which were relatively rare. If we assume that arsenic was the only poisonous agent at work, we must also admit that it caused grave poisoning in very minute doses; in some cases, from the published records, these must have been as small as 1/200th of a grain per diem.

[1] *Ast. Phys. Journ.* vol. xii. p. 51, 1891.

[2] The latest photograph, taken on April 1 shows this peculiarity in a far more pronounced manner, the intensity of the less refrangible component of the hydrogen lines being more than four times that of the more refrangible component.

These profound symptoms of poisoning from such minute doses have given rise to various explanations. The fact that the toxic power of arsenic varies largely according to the chemical form in which it is present, the arseniates, for instance, being barely half as poisonous as the arsenites, has led many to assume that the arsenic was present in the beer either as an arsene, or even in some more subtle biological form. The work of Gossio and others upon the power of the penicillium brevicaule to form highly poisonous gaseous substances from minute traces of solid arsenic compounds has been adduced by many in support of this hypothesis.

A further consideration of interest in this connection is the fact that arsenic must be considered, at any rate to some extent, a cumulative poison. The interesting and minute work of Gautier upon the excretion of arsenic under normal conditions by the skin, the hair and the menstrual fluid, and the storing of it in the thyroid gland, the thymus gland and the brain, are of especial interest. The recent researches of Sslowzow should also find mention here. This observer found that in animals poisoned with arsenic the arsenic was stored in the liver, and further, that it formed a compound with the nucleins, which showed itself to be resistant to the action of hydrochloric acid and pepsin, and that it was, in all probability, stored in this form in the cell nuclei. This work, so far as concerns the storing of arsenic in the liver and its excretion by the epidermal appendages, has been recently confirmed by Dixon Mann.

That arsenic is slowly excreted has been known for some time. E. Ludwig found arsenic in the urine of a dog forty days after the last dose had been ingested, Wood found it in the urine of patients eighty and ninety days after intoxication with arsenic.

Although arsenic may be in this sense cumulative, it does not follow that its poisonous action is cumulative. In fact, its forming an indigestible nuclein compound speaks against this. Further, we know from clinical experience, from the Styrian arsenic eaters, and from numerous pharmacological experiments on animals, that tolerance to arsenic is easily produced. Indeed, continued small doses of arsenic, so far from causing symptoms allied to those which occurred in the beer poisoning epidemic, as a rule improve nutrition and have a general tonic action.

If we pass from the consideration of the nature of the poison to the symptoms which occurred in the Manchester patients, we find many points of extreme interest. Speaking generally, the phenomena present corresponded more or less closely with the classical symptoms of arsenical poisoning. It must be remembered, however, that the discovery of selenium opens the whole question of arsenical poisoning afresh. So far as pharmacological experiments upon animals go, the only difference between the chronic poisonous action of these two substances is that tolerance to selenium is apparently never produced, and that this substance, in continued small doses, produces wasting by virtue of a specific stimulating action which it exerts upon the breaking down of the nitrogenous constituents of the tissues. Thus we must confess that the presence of selenium along with arsenic in the Manchester beer explains many otherwise anomalous symptoms.

It has long been known that excess of alcoholic beverages causes in the drinkers a disease known as peripheral neuritis. The *rôle* played by alcohol in this disease has heretofore been regarded as sufficiently important to justify the designation of alcoholic neuritis for this condition. It has, however, been observed that the drinkers of certain kinds of alcoholic beverages are much more prone to this affection than the drinkers of others, and further, that the strength of the beverage in alcohol seems to bear no proportion to its proneness to cause so-called alcoholic neuritis. Drinkers of distilled spirits and wines are much less liable to suffer from peripheral neuritis than beer and stout drinkers. These considerations have led many physicians to look upon this disease as caused by the beverage rather than by the alcohol (C_2H_5OH). Peripheral neuritis was a prominent symptom in the Manchester epidemic, and there can be little doubt it was caused by the arsenic and selenium compounds in the beer. Other metallic and organic poisons, such, for instance, as beri-beri, give rise to a similar condition. This epidemic has, therefore, very much increased the previous doubt concerning the part played by alcohol itself in the so-called alcoholic neuritis.

With regard to the lessons to be learnt from the recent beer-poisoning epidemic, the chief one certainly is to beware of mineral acids in the preparation of all foodstuffs. It is difficult to see how mineral acids, or at any rate acids (in this connection must be observed the difficulty of freeing an acid like tartaric acid from lead) can be dispensed with. They can, however, certainly be put on the market, from whatever source they may be obtained, pure. Although absolute chemical purity must be regarded as a dream of the fatuous ignoramus, there should be no difficulty in the sulphuric acid manufacturers providing an acid which one can term at least harmlessly impure. A further important result of the investigations attending this epidemic is the discovery of selenium in poisonous doses in a beverage actually consumed. This substance has no doubt slipped in and out of many previous arsenic epidemics, escaping observation, as it were, between the stools of chemistry and pharmacology. Now that we are awake to its poisonous existence, in the next arsenic epidemic, which we hope may be long deferred, we shall be able, no doubt, to work out the exact part it plays. It is interesting to note in this connection that it is an impurity of both brimstone and pyrites acid, and that it occurs along with tellurium in certain Japanese sulphurs which are free from arsenic.

MUSICAL ARCS.

WE have already described in a previous issue (NATURE, December 20, 1900, p. 182) the discovery of a new musical instrument in the electric arc made by Mr. Duddell and communicated by him to the Institution of Electrical Engineers last December. The fame, if not the music, of Mr. Duddell's arc penetrated, it appears, to Vienna, where the experiments were repeated at the Technological Institute, and thence returned to the English lay Press. The *Daily Mail* of January 12 last contained an article on "Music in Flame," the result of an interview with Prof. Ayrton on the subject of Mr. Duddell's experiments, in the course of which he suggested that it might be possible to utilise the discovery for the purpose of public entertainment. Would it not be possible, for example, to play a tune upon the arc lamps used in lighting a hall, the musician being at a distance—even outside the building—and playing on the ingenious key-board devised by Mr. Duddell? At the time this article appeared the prophecy may have seemed somewhat extravagant. Mr. Duddell's experiments were conducted, it will be remembered, by shunting an arc burning between solid carbons—the cored carbon arc has no music in its soul—by a circuit containing capacity and self-induction, and the note emitted by the arc was varied by altering the capacity or self-induction in the shunt circuit. The shunt circuit was, however, placed directly across the terminals of the arc, and there was no evidence of any possibility of playing tunes on the arc from any distance; and, further, the arc lamps used in the experiment were hand-fed and it was not unreasonable to suppose that the mechanism and magnet coils of an automatic arc lamp would effectually interfere with the music.

Extravagant, however, as Prof. Ayrton's suggestion may have seemed, it appears from Mr. Duddell's reply to the discussion on his paper (just published in the *Journal* of the Institution of Electrical Engineers) that it is more than justified by the truth. During the time that Mr. Duddell was experimenting on the musical arc at the Central Technical College, Mr. Bradfield noticed that an arc with which he was experimenting in Sir W. de W. Abney's laboratory started playing tunes. About the same time also Sir Norman Lockyer noticed that the arc in his laboratory was behaving in an erratic manner, though he did not detect any definite tune. At the time neither Mr. Bradfield nor Sir Norman Lockyer were able to account for this strange behaviour, but on the publication of Mr. Duddell's paper the explanation became evident. All the arcs were being supplied from the street mains and the disturbances were due to the shunt circuit with which Mr. Duddell was working at the Central Technical College. The arcs at Sir W. Abney's and Sir Norman Lockyer's laboratories were thus able to detect and repeat the tunes Mr. Duddell was playing on his arc, although they were in no way adjusted to make them specially sensitive, and were only connected to Mr. Duddell's arc by virtue of being on the same distributing network of supply mains. Sir. W. Abney's laboratory is on the opposite side of the road to the Central Technical College and at a distance of about 400 yards in a straight line, and at a much greater distance if measured along the street mains. Sir Norman Lockyer's laboratory is at about the same distance, on the same side of the road as the College.

If such remarkable results as these can be obtained without any design or arrangements of the circuit, who shall say what cannot be effected by a proper study of the best conditions and attention to the necessary details? Those who heard the music discoursed by the arcs at the Institution of Electrical Engineers will agree that some improvement is necessary before the arc can compete as a musical instrument with the violin or grand organ. But it is sufficiently demonstrated, we think, that Prof. Ayrton's prophecy is by no means excessive, and the time is perhaps not far distant when every central station will have its resident musician to play patriotic airs on the street arcs at the Coronation of the King and like occasions, and we shall be able to realise something of the grandeur of "the morning stars singing together."

LITTLE'S EXPEDITION TO OMI AND THE TIBETAN BORDER.[1]

A HOLIDAY trip from Central China (Chung-King), through the red sandstone basin of western Sze Chuan to the granite frontiers of Tibet, and back again by the traditional water-highway of the Yangtse, is not an experience which falls within the reach of every mercantile explorer in the East; and it derives additional interest in Mr. Little's case from the fact that he was accompanied by his wife. The story of the expedition is told in the form of a diary, a form in which it is almost impossible to avoid a certain amount of monotonous reiteration of incident in the daily record of progress, and which is, perhaps, a little too official in its method for an ordinary traveller's tale; but it is interesting all through, and the deductions which Mr. Little draws from his observations afford valuable food for reflection to those who look to the opening up of China to western methods of economic development. From Chung King to Kia ting, the town which lies at the foot of the classical Omi (the Fusilama of western China), Mr. Little and his wife adopted the Chinese traditional mode of transport, which consists of a sedan chair carried on the shoulders of coolies; and it is a method which, in the present stage of Chinese social advancement, secures for a traveller as much respect and attention as a coach-and-four would in England. It at once lifts him morally and physically above the steaming crowds of humanity which, in a region which is free from the depleting processes of famine, swarm together in one great pitiless struggle for existence. The whole basin of the Yangtse to the foot of the western mountains presents the same aspect of overcrowded population. Every acre of available soil is cultivated, every yard of productive land is occupied. There is no room to pitch even the smallest of tents, and travellers have perforce to put up with the accommodation afforded by the indigenous hotel. It is the varied nature of the sort of entertainment which is found at these Chinese inns, with the everlasting accompaniment of personal unrestrained curiosity on the part of a people who look on all foreign devils (especially a feminine devil) as fair game for their inquisitiveness, which forms the leading feature in Mr. Little's account of his outward journey. The trip was made in 1897, and it is worthy of remark (*àpropos* of more recent events in China) that even then Mr. Little was able to discern a very considerable change for the worse in the attitude of the people towards strangers; and this change had taken place during the previous ten years. Fifteen years before Mr. Little's journey that delightful writer and traveller, Baber, had visited western Sze Chuan and Mount Omi, and his account of his travels certainly tends to confirm Mr. Little's view that a growing antipathy to foreign incursions was gradually accumulating which would eventually tend to mischievous results. Our travellers were occasionally treated to something worse than the derisive jeers of the townspeople. "Clods of earth and cabbage-stalks" now and then followed the maledictions of the crowd. And yet there was much good-natured hospitality and courtesy frequently shown both by priests and people. How far the interference of missionaries with the old traditions of a form of Buddhism which seems to be of a far higher and purer type in western China than anything in Tibet, may have influenced the minds of the people is open to question. Mr. Little is evidently doubtful on the point. With every desire to give missionaries credit for their devoted spirit of enterprise, he seems to think that their efforts in the work of regeneration have not always been wisely directed.

Of the wonderful beauty of Mount Omi scenery, its temples and groves, its priests, its pilgrims and its precipices (from the summit of one of which the crowning "glory of Buddha" is to be seen), Mr. Little has much to say, and he says it well. When the Chinese introduce railways more freely into their country, along with that "western knowledge and machinery" which is to give to them the "command of the industrial world," Omi (beloved of Baber and photographed by Mrs. Little) will be as much an object of western pilgrimage as of eastern.

Mr. Little makes the height of Omi to be 10,500 feet above sea, and Sai King Shan (a mountain which he subsequently visited), 11,100. This exactly reverses the altitudes given by Baber, who makes Omi 11,100 feet—the height which is preserved in Mr. Little's map. Hypsometrical determinations are proverbially unsatisfactory, especially when the observations are made under the influence of very varied "weather" conditions. Possibly, also, Mr. Little's results may be affected by the fact that he "boiled his thermometer" (he says he did so, repeatedly) instead of registering the temperature of the steam.

The Littles did not penetrate far into Tibet. Indeed, it depends on whether Ta chien lu (Dar chen do; both names seem to be correct) is to be regarded as the frontier of Tibet, or whether the boundary is politically (as it is geographically) to be found in the Tung river.

[1] "Mount Omi and Beyond." By A. J. Little. Pp. xiv + 272. (London: W. Heinemann, 1901.)

Ta chien lu is a typical Tibetan town, with its "curved roofs, gilded pinnacles surrounded by a mediæval wall," and its extensive and gaudy "lamasarai" Walled in by gigantic mountains as it is, Ta chien lu has become a most important economic and strategical centre. Since the Koko Nor trade route has been abandoned, all the trade of Tibet (skins, wool, gold and musk) passes into China this way; and it is by this route that the soft, irruptive Chinese tide made its way, by sheer force of patient persistence, into the strongholds of the hardy Tibetan and reduced Tibet to a dependency. Mr. Little hardly appreciates the chicken-hearted nature of Tibetan morale, so much is it disguised by the stalwart, muscular personality of the mountain-bred nomad. The Tibetan submits to slipshod Chinese domination without a murmur.

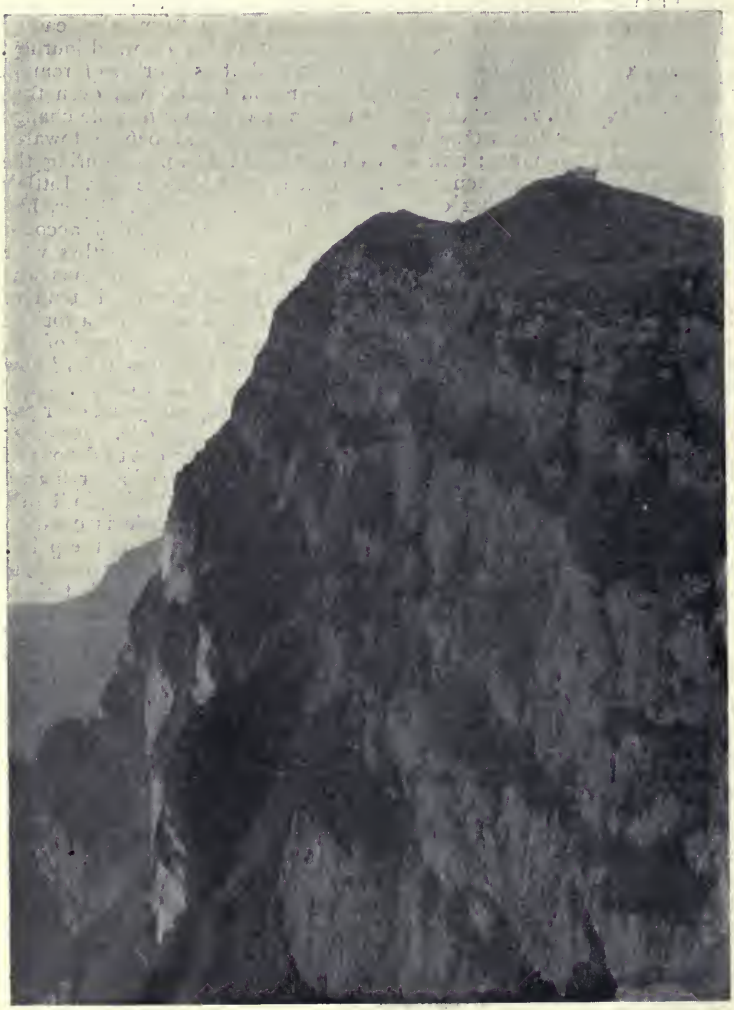

FIG. 1.—Summit of Mount Omi, with Temples.

Ta chien lu is the great western tea mart, and the trade (along with pawnbroking, according to other observers) is altogether in the hands of the Lamas. The manufacture of brick tea for the Tibetan market is faithfully described. It is enough to say that Tibetans like the tea so manufactured, and will "use no other." The bridge at Luting over the Tung, which alone makes the route practicable, is a work of Chinese enterprise which has now lasted for 200 years without repair. It is an iron suspension bridge, and for details of its construction (which are really worth attentive study) the reader cannot do better than refer to Mr. Little's book.

The return journey down the Yangtse, through the rapids and reaches of its upper course, is a feature in the story which will be more or less familiar to many recent travellers. The book is interesting throughout, and not the least value of it is the vista which it opens up of future economic possibilities in that teeming eastern region, the Yangtse basin.

PROF. JOSEF VON FODOR.

BY the death of Prof. von Fodor, of Budapest, the eastern part of Europe has lost its great teacher of hygiene, and the world one of its most diligent investigators in the domain of public health. His investigations had chiefly to do with the soil, subsoil water and ground air, and his authority on these matters is universally recognised. His chief treatises were on air, water and soil in connection with diseases, to which a happy reference was made by the public orator at Cambridge when von Fodor was awarded the hon. LL.D. degree on the occasion of the London meeting of the International Congress of Hygiene and Demography in 1891, as follows:—

"Quis nescit urbem florentissimam, quod Hungariæ caput est, nomine bilingui nuncupatam, fluminis Danubii in utraque ripa esse positam. Quis non inde nobis feliciter advectum esse gaudet salutis publicæ professorem insignem, virum titulis plurimis cumulatum, qui etiam de Angliæ salubritate opus egregium conscripsit? Idem, velut alter Hippocrates, de aëre, aquis et locis præclare disseruit. Olim Hippocrates ipse corona aurea Atheniensium in theatro donatus est; nos Hippocratis æmulum illustrem laurea nostra qualicunque in hoc templo honoris libenter ornamus.

Duco ad vos bacteriologiæ cultorem accerrimum, Iosephum de Fodor"

Of this degree von Fodor was justly proud, as he showed by wearing the scarlet gown to which it entitled him on important occasions.

He was a sincere, unaffected and amiable man, whose premature death has been a very severe shock to his many friends and admirers.

W. H. C.

NOTES.

A MEETING of the local branch of the general committee for the purpose of founding a memorial to the late Prof. Fitzgerald was held on March 28 in Trinity College, Dublin. Dr. Tarleton presided. The meeting was attended by representatives of the leading societies and clubs of the University. It was resolved that the proposed memorial would most appropriately take the form of an endowment of research in physical science by advanced students. In this manner the work of the late professor would best be carried forward. Letters were read from many distinguished scientific men expressing sympathy with the movement. An executive committee was elected and

empowered to take the requisite steps to afford the many friends and admirers of the late Prof. Fitzgerald an opportunity of forwarding the object in view.

M. SABATIER, professor of chemistry in the University of Toulouse, has been elected a member of the section of chemistry of the Paris Academy of Sciences, in succession to M. Haller, who has been elected a member of the Academy. Prof. Davidson, of the University of California, has been elected a correspondant of the section of geography and navigation.

THE American Academy of Arts and Sciences elected the following foreign honorary members at the last meeting:—Prof. J. H. Poincaré, Paris (Mathematics and Astronomy); Prof. Henrich Müller-Breslau, Berlin (Technology and Engineering); Prof. H. Kronecker, Bern (Zoology and Physiology); Prof. R. Koch, Berlin (Medicine and Surgery); Sir T. Lauder Brunton, London (Medicine and Surgery); Prof. A. V. Dicey, Oxford (Philosophy and Jurisprudence); Mr. W. E. Hearn, Melbourne (Philosophy and Jurisprudence); and Dr. Henry Jackson, Cambridge (Philosophy and Archæology).

THE ninth James Forrest lecture of the Institution of Civil Engineers will be delivered by Dr. Frank Clowes on April 25. The subject will be "Chemistry in its Relations to Engineering."

THE *Frankfurter Zeitung* announces the death, at Waiblingen, Wurtemberg, from malaria, of Dr. Schlichter, the well-known African traveller and geographer.

THE death is announced of Mr. W. Hodgson, who for more than half a century devoted his leisure to the collection of facts relating to the flora of his native county, Cumberland. He was the author of a "Flora of Cumberland," which was published about two years ago.

THE *Athenaeum* announces the death of Dr. Franz Melde, professor of astronomy and physics and director of the mathematical and physical institute of the University of Marburg, on March 17, at the age of sixty-nine. Dr. Melde distinguished himself in every branch of experimental physics, notably in his special subject acoustics, and his book on "Zeitbestimmungen" proved a valuable contribution to astronomy.

REUTER'S Agency is informed that the whaler *America*, which has been bought by Mr. Evelyn B. Baldwin, the American explorer, for his forthcoming journey to the North Pole, will sail from Dundee on June 18, by which date Mr. Baldwin expects to arrive from the United States. The *America* will proceed direct to Norway, where she will join the two other ships which are to form part of the expedition, and, after taking on board stores and equipment, will procee for the North.

THE ship which has been built for the German Antarctic Expedition was launched at Kiel on Tuesday. The Berlin correspondent of the *Times* states that among those who were present at the ceremony were Count Posadowsky, the Secretary of State for Home Affairs, Prof. von Drygalski, who will have charge of the expedition, and representatives of the Foreign Office, the Admiralty, and the local authorities. The vessel was christened the *Gauss* by Prof. Baron von Richthofen, who the course of a short speech said that the German nation would follow the fortunes of the expedition with hope and with anxiety. The name *Gauss* was selected by order of the Emperor in honour of the Göttingen professor, the late Karl Friedrich Gauss, who did much to stimulate Antarctic research. A telegram was received from Count von Bülow cordially wishing the expedition every success.

THE following are among the lecture arrangements at the Royal Institution, after Easter:—Dr. Allan Macfadyen, six lectures on cellular physiology, with special reference to the enzymes and ferments; Mr. Roger Fry, two lectures on naturalism in Italian painting; Prof. Dewar, three lectures on the chemistry of carbon; Prof. W. M. Flinders Petrie, three lectures on the rise of civilisation in Egypt; Prof. J. B. Farmer, two lectures on the biological characters of epiphytic plants; Mr. J. Y. Buchanan, three lectures on climate: its causes and effects. The Friday evening meetings will be resumed on April 19, when a discourse will be delivered by Prof. J. J. Thomson on the existence of bodies smaller than atoms. Succeeding discourses will probably be given by Dr. Hans Gadow, Mr. Charles Mercier, Prof. J. Chunder Bose, Mr. R. T. Glazebrook, Mr. A. Henry Savage Landor, and other gentlemen.

THE annual meeting of the Iron and Steel Institute will be held in London on May 8 and 9. As a tribute of respect to the memory of her late Majesty the Queen, it has been decided that the usual annual dinner shall not be held this year. At the opening meeting on May 8 the retiring president, Sir William Roberts-Austen, K.C.B., will induct into the chair the president-elect, Mr. William Whitwell. The Bessemer Gold Medal for 1901 will be presented to Mr. J. E. Stead. Among the papers that are expected to be submitted to the meeting are the following:—On the properties of steel castings, by Prof. J. O. Arnold; on the physical properties of steel, by Mr. J. A. Brinell; on the heat of formation of carbides and silicides of iron, by Mr. E. D. Campbell; on the use of hydraulic power in the manufacture of iron and steel, by Mr. R. M. Daelen (Düsseldorf); on dust in blast-furnace gas, by Mr. A. Greiner; on the economical significance of high silicon in pig iron for the acid steel processes, by Mr. Axel Sahlin; on crystals of carbo-silicide of manganese and iron from a blast-furnace burden, by Mr. J. E. Stead; on the effect of copper in steel rails and plates, by Messrs. J. E. Stead and John Evans (Middlesbrough); on the measurement of Young's modulus for iron rods by tension and by bending, by Mr. H. E. Wimperis. The autumn meeting of the Institute will be held in Glasgow on September 3 and following days, simultaneously with the holding of the International Engineering Congress, of section V. (Iron and Steel), of which the Iron and Steel Institute has undertaken to take charge.

THE annual general meeting of the Chemical Society was held on Thursday, March 28. Dr. T. E. Thorpe, who occupied the chair, referred to the death of her late Majesty Queen Victoria, and said he was proud to think that the Chemical Society, in so far as it had ministered to the progress of chemistry, contributed in some measure to the lustre of a reign so pre-eminently associated with the development and spread of science in this country, and with the extension of those arts which rest upon chemistry. During the past year the publications of the Society were exceptionally full and valuable. The volume of *Transactions* for 1900 contained no less than four memorial lectures, giving an account of the life-work of Victor Meyer, Bunsen, Friedel and Nilson. The council had determined to issue those memorial lectures which had appeared up to the end of 1900 in a separate form. Acting upon the result of the voting of the Fellows on the question of the day and hour of meeting, the council had decided that the suggested change should be provisionally tried during the coming session. The ordinary meetings of next session would therefore be held on the first and third Wednesdays of the month, at 5.30 p.m. A reference was made to the movement for a uniform system of atomic weights, and it was announced that a committee of the Society had decided to recommend (1) that $O=16$ be taken as the basis of calculation of atomic weights; (2) that in assigning a number as the atomic weight of any element only so many figures should be employed that the last may be regarded as

accurately known to one unit in that figure. Prof. J. Emerson Reynolds was elected president of the Society, in succession to Dr. Thorpe. At the annual dinner of the Society, held on Wednesday, March 27, toasts were proposed and acknowledged by Dr. Thorpe (who presided), Prof. Tilden, the Lord Chancellor, Sir Herbert Maxwell, Lord Kelvin, Prof. Dewar, Mr. A. B. Kempe, Prof. S. P. Thompson, Prof. Emerson Reynolds, Sir W. S. Church, Sir Francis Mowatt and Sir Henry Roscoe.

AT the annual meeting of the Institution of Naval Architects, on March 27–29, the Earl of Glasgow was elected president. The next meeting of the Institution will be held at Glasgow, on June 25–28. An international engineering congress will be held in Glasgow early in September, and the Institution has undertaken the management of the section relating to naval architecture and marine engineering. The Earl of Glasgow delivered an address, in which he reviewed the progress of shipping during the past year, commenting upon the announcement recently made by the First Lord of the Admiralty, that, for the first time in our history, submarine boats have been ordered for experimental purposes. At the close of the president's address, Prof. G. H. Bryan, F.R.S., was presented with the gold medal of the Institution for his paper on the action of bilge keels. Prof. J. H. Biles then read a paper on naval construction in the United States. Among other matters he noted some rather important details common to the larger classes of American ships. Cofferdams filled with obturating material, which is expected to expand when in contact with the water, are fitted very generally at the sides of the ship. This material is the pith of the corn stock, and has been experimented upon very fully by the navy department, with the result that designs have been prepared with the intention of adopting it generally. It is evident that if the corn stock material swells when in contact with water sufficiently to fill up holes made by shot, it will have an important effect upon the margin of stability and probably of buoyancy of a ship in action. Another paper read before the Institution was on an instrument for measuring the rolling of ships, by Mr. A. Mallock, who, after pointing out the difficulty of accurately measuring the angle of roll of a ship, described an indicator which would give a very accurate measure of the rolls in all circumstances.

IMPORTANT papers were read at the meeting referred to in the foregoing note. Herr Otto Schlick described experiments to determine the cause of small vibrations in the *Deutschland* during her trial trip in June last. The conclusion arrived at from his experiments is that one blade of the propeller has a greater resistance in turning than the other blades, or that the opposite blade has a correspondingly less resistance. Such greater resistance of the one blade is in most cases probably to be attributed to its greater pitch. The least deviation in the pitch, which cannot be proved by ordinary instruments, appears to cause perceptible vertical vibrations, and therefore the greatest care should be taken in the manufacture of propellers, not only for the sake of doing away with vibration, but also to save power and prevent breakage of the blades. Mr. C. H. Wingfield discussed the view that the thrust of a submerged propeller is greatest on those parts of the blade which are most deeply immersed, and gave reasons for an opposite conclusion. Papers on the mathematics of engine-balancing were read by Mr. J. Macfarlane Gray and Prof. W. E. Dalby. Captain W. Hovgaard, of the Danish Navy, dealt with the motion of submarine boats in a vertical plane. He pointed out that for such submarine boats as are now generally constructed, of from 100 to 200 tons displacement, and with our present means of underwater propulsion, a speed above twelve knots must be considered high. Mathematical considerations show that such boats should be long, deep, and comparatively narrow, with great metacentric height. Moreover, the necessity for drawing the centre of gravity forward and the centre of lateral resistance aft leads to a deep, narrow forebody and a flat and broad aftbody, with large horizontal fins aft. The French submarine boats *Gustave Zédé*, *Morse* and others approximate to this type. Boats of less than six knots may be regarded as of low speed. In such boats great length is not necessary, and, on the whole, is objectionable as regards internal arrangements and weight of hull. In them it is not requisite to draw the centre of lateral resistance so far aft of the centre of gravity as in the high-speed boat, and they should, therefore, be of short length, small depth and great breadth. The metacentric height should be made as great as possible by a low centre of gravity, and large horizontal fins should be fitted aft. The Holland Torpedo Boat Company's first boat, the *Holland*, approaches this type, but differs in having greater depth and stability. For submarine boats to be able to travel below the surface for a distance of two, or perhaps three, miles is sufficient for most purposes.

MR. H. G. WELLS commences, in the current number of the *Fortnightly Review*, a series of speculative papers upon some changes of civilised life and conditions of living likely to occur in the new century. To construct a prehistoric animal from one or two fossil bones is a much easier task than the prediction of future developments from the point of view of the present; but Mr. Wells attempts to do this, and even if his prophetic visions do not materialise they will convince the conservative mind that there is some virtue in dissatisfaction at many of the methods of to-day. The subject of the first article is land locomotion in the twentieth century, and it scarcely requires a prophetic afflatus to know that the present systems will be largely superseded or modified. Horse traffic, with its cruelty and filth, while the animals exhaust and pollute the air, must give place to motor carriages in a few years. The railways will then develop in order to save themselves. There will be continuous trains, working perhaps upon a plan like that of the moving platform of the Paris Exhibition, or utilising the principle of the rotating platform outlined by Prof. Perry in these columns (vol. lxii. p. 412, 1900). Nothing is said about the possibilities of aëronautics, not because of any doubt as to its final practicability, but because "I do not think it at all probable that aëronautics will ever come into play as a serious modification of transport and communication." It is, of course, impossible to project ourselves into the future so as to say exactly what will or will not come to pass; for an estimate of future performances can only be made with the material now available, and it leaves out of account the completely novel discoveries which often revolutionise the whole conditions. Nevertheless, it is not unprofitable to meditate upon the promise of progress.

AN address on weather knowledge and agriculture, delivered by Dr. Richard Börnstein at the Royal College of Agriculture of Berlin, in celebration of the Kaiser's birthday and of the two hundredth anniversary of the foundation of the kingdom of Prussia, has recently been issued in pamphlet form ("Wetterkunde und Landwirtschaft." Berlin: Paul Parey). Its concluding pages refer in most complimentary terms to the Kaiser's generous share in the promotion of scientific ballooning in Berlin, but the bulk of the address deals with the development of the German service of weather forecasts, and with suggestions for improving their accuracy and utility. Dr. Börnstein would have forecasts issued by local meteorological authorities, based on information supplied by telegraph from a central department and supplemented by knowledge of local climatology; he would also secure a more intelligent use of the information conveyed in the forecasts by the extension of instruction in the laws

of atmospheric changes. It is not in Germany alone that such knowledge would be of advantage. There are occasions in which the weather in any one or more of the districts of the British Isles could be easily characterised by a single word of one or more syllables, but to go a little further into detail and make a forecast describing the weather of the ensuing twenty-four hours in ten words, and no more, requires, on the part of the recipient, some intelligent acquaintance at least with weather telegraphese. It appears that in Germany the local authorities have taken the matter up with the prospect, according to Dr. Börnstein, of securing a more effective weather service than any other country in Europe.

THE paper on combined trolley and conduit tramway systems, read by Mr. A. N. Connett at the last meeting of the Institution of Mechanical Engineers, is one of considerable interest and importance. Of the four systems of electric tramways only the conduit and the trolley can be considered to be commercially practicable, since the surface contact system, though not wanting many and distinguished advocates, can hardly be said to be properly out of the experimental stage, and the accumulator system is still waiting for a thoroughly satisfactory traction cell. The trolley and the conduit are both in wide use, especially in America and on the Continent, and there are many lines at work combining the two systems. The trolley is objected to in large towns on the ground of its ugliness, its potential danger and the disadvantage involved in using the track rails as a return conductor. The conduit, on the other hand, is too expensive for country or suburban lines where the cheaper trolley is admissible. We have, therefore, in the case of tramways running into crowded towns from the outlying districts, a need for a combined system; this involves a special construction of the car to enable a quick change to be made from the one system to the other at the point of junction, and it is the problem thus raised that Mr. Connett discusses. The paper also deals at some length with the relative merits of side and centre slots for the conduit system, and gives a comparative estimate of the costs of installing conduit and trolley systems respectively; it is to be noted that the conduit is about twice as expensive as the trolley.

ACCORDING to a recent report the expectations of the constructors of the great Chicago Drainage Canal, which was made for carrying away the sewage of the city, containing over a million inhabitants, have been realised. The idea of pouring the sewage of a large city, amounting to 50,000 cubic feet a minute, into an open channel and allowing it to flow away without any attempt at purification was both novel and startling. Now it appears, after eight months' working, none of the actions threatened by the towns bordering on the river below Chicago have been commenced, and it is reported by competent authorities that the water in the canal is free from objectionable features. In fact, the water-way is used largely by pleasure boats and the water taken by the manufactories situated on the banks. It has also been found, on investigation by the Government Commission, that so far no appreciable effect has been made in lowering the water in Lake Michigan, a consequence that excited at one time great fears on the part of the harbour authorities round the coast. The immunity from the objectionable conditions which prevail in the Manchester Ship Canal owing to sewage being discharged into it is due to the large volume of clean water that is always passing down the water-way from Lake Michigan, a stream 22 feet deep and running at the rate of a mile an hour being sufficient to neutralise the foul condition of the 50,000 cubic feet of sewage sent into it every minute.

THE embryos of the New Zealand tuatera lizard recently received in this country have afforded to Mr. H. S. Harrison opportunities for studying the early dental developments of that remarkable reptile, the results of which are published in the *Quarterly Journal of Microscopical Science* for March. The outcome of these studies is to show that Sphenodon (or, as it is often incorrectly called, Hatteria) in its early stages possesses numerous sharp-pointed teeth very similar to those of many ordinary lizards; and as these are of irregular size at a certain period, it is inferred that they represent several coalesced dental series. On the completion of this alternating series a period of repose occurs, after which a development of uniform teeth takes place. By a secondary formation of bone round their bases, these teeth acquire what may be called false sockets. Subsequently the sides of the jaws are invested with a highly calcified layer of bone, which, when the teeth become worn down and the sides of the jaws exposed, assists the edges of the latter in the assumption of dental functions in the adult.

TO those interested in domesticated animals, whether from the point of view of the breeder or of the study of variation under human influence, the spring number of *Bibby's Quarterly* should prove very welcome, as it contains an unusually large number of reproductions of photographs of prize and other cattle, sheep, horses, &c. As marking the changes introduced by breeders, such photographs are of very considerable importance, and their reproduction in a journal of this description renders them accessible to all. A feature of the present number is an article by Prof. J. C. Ewart on "Prepotency and Exclusive Inheritance." The numerous photogravures in this article illustrate the predominating influence of one or other parents on their offspring in many breeds of domesticated animals. In an article on Boer farm life, attention cannot fail to be arrested by the photogravures of an arum-field and of flocks of domesticated ostriches. Arums, it appears, are grown as food both for pigs and ostriches.

OPPORTUNITY to study the geology and physical geography of the basin of the Thames is afforded by the Saturday afternoon excursions of the London Geological Field Class, which commence on April 27. Visits have been arranged to places of geological interest both north and south of London, and the excursions provide exceptional facilities for examining some of the greater movements which the south-east of England has experienced. Particulars can be obtained from the honorary general secretary, Mr. R. H. Bentley, 43, Gloucester Road, Brownswood Park, N.

REFERRING to the periodic variations of glaciers, the remark was made in our issue of March 7 (p. 444) that, in the Swiss Alps "of fifty-seven glaciers observed in 1897, fifty were still decreasing, five were stationary and twelve were increasing." A correspondent points out that this would make sixty-seven glaciers observed, and the author informs us that the difference arose from a clerical error in copying the numbers from the original memoir. The number thirty-nine should be substituted for fifty, making the total number of glaciers observed to be fifty-six instead of fifty-seven.

THE first place in the March number of *La Geographie* is given to a review of Colonel Yates' book on Khurasan and Sistan, by Prof. Vambéry. M. Bonin continues his account of a journey from Pekin to Russian Turkestan by Mongolia, Koko-Nor, Lob-Nor and Dzoungaria. Papers on three expeditions in the French Congo region are contributed by MM. Jobit, Lœfler and Huot, and Mr. J. W. Hodge reviews recent ethnographic and archæological explorations in the United States.

WE have received a copy of the "Report of Progress of the Survey of Tides and Currents in Canadian Waters" for the year ending June 30, 1900, by Mr. W. Bell Dawson, engineer in charge. Considerable advance has been made in the preparation of tide-tables, and a pamphlet issued during the year on the currents in the Gulf of St. Lawrence has already been

noticed in these columns. The observations secured during the year will, when worked up, afford an accurate knowledge of the times of the tides and of the turning of the tidal streams in the lower St. Lawrence. Many new observations of the tide-levels at different stations have also been obtained.

A METHOD for the preparation of amides from the corresponding aldehydes, which appears to be of general application, is described by Messrs. Pickard and Carter in the April number of the *Journal* of the Chemical Society. The aldehyde dissolved or suspended in water is shaken with a slight excess of ammonium persulphate and a certain quantity of lime, and after the reaction is over there is no difficulty in separating the amide in quantities amounting to 30 to 40 per cent. of the aldehyde taken. The method also lends itself to the preparation of alkyl-substituted amides, potassium persulphate being substituted for the ammonium salt and the alkylamine being present.

THE following species, among others, have been taken at Plymouth recently by the Marine Biological Association:—Mollusca: *Æolis aurantiaca*, *Gastrochaena modiolina*. Crustacea: *Achaeus Cranchii*. Polychæta: *Magelona papillicornis*, *Owenia fusiformis*, *Scalisetosus assimile*. Echinoderma: *Ophiocnida brachiata*. Hydrozoa: *Heterocordyle Conybeari*, *Syncoryne Loveni*. The pelagic fauna is increasing in richness and variety. The following have been taken:—Medusæ: *Amphicodon amphipleurus*, *Margelium octopunctatum*. Crustaceæ: *Podon intermedius*; large numbers of the nauplii and the *Cypris* stage of *Balanus*. Polychæta: post-larval stages of *Arenicola*, Trochospheres and later larvæ of Polynoids and Phyllodocids. Among the species breeding may be mentioned the following:—Crustacea: *Porcellana platycheles*, *Zantho rivulosus*; several species of *Portunus* and *Stenorhynchus phalangium*. Polychæta: *Myrianida pennigera*, *Polynoe scolopendrina*. Hydrozoa: *Hydrallmania falcata*, *Tubularia indivisa*, *Syncoryne Loveni*, *Garveia nutans*, *Diphasia rosacea*, *Sertularia argentea*, *Eudendrium ramosum*.

THE additions to the Zoological Society's Gardens during the past week include a Vulpine Phalanger (*Trichosurus vulpecula*) from Australia, presented by Mr. R. Kirkwood; a Patas Monkey (*Cercopithecus patas*) from West Africa, presented by Mr. H. E. Jung; a Common Coot (*Fulica atra*), European, presented by Mr. M. C. H. Hammond; two Picui Doves (*Columbula picui*) from South America, a Red-vented Bulbul (*Pycnonotus haemorrhous*) from India, presented by Mr. D. Seth-Smith; a Huanaco (*Lama huanacos*) from Bolivia, a Tawny Eagle (*Aquila naevioides*) from the Seychelles, a Nilotic Crocodile (*Crocodilus niloticus*) from Africa, four Menobranchs (*Necturus maculatus*) from North America, a West African Python (*Python sebae*) from West Africa, deposited; two Straw-necked Ibises (*Carphibis spinicollis*) from Australia, purchased; a Sykes Oriole (*Oriolus kundoo*), received in exchange.

OUR ASTRONOMICAL COLUMN.

RUTHERFURD MEASURES OF PLEIADES.—In the *Contributions from the Observatory of Columbia University*, No. 17, Mr. Harold Jacoby furnishes a revised discussion of the series of measures made by Rutherfurd of photographs of the Pleiades group dating from the years 1872 and 1874. The results of the first investigation were published in 1892, and are slightly modified in the present paper. Special reductions have been made to test the possibility of there being systematic errors arising from some form of optical distortion of the object-glass, and comparisons are given of heliometer and photographic measures. The final data are collected to form a catalogue of seventy-five stars in the cluster.

CATALOGUE OF SOUTHERN VARIABLE STARS.—Mr. Alexander W. Roberts has recently published in the *Astronomical Journal* (Nos. 491 492) a catalogue of the positions, magnitudes and elements of variable stars south of $-30°$ declination, reduced from observations made at the Lovedale Observatory with a $3\frac{1}{4}$-inch telescope during the years 1891–1899. In connection with the elements a new departure has been made by considering the epoch of a variable as the first maximum passage during 1900, all the stars being uniformly treated on this plan, except that Algol-variables are reckoned from the first *minimum* passage.

The author finds that the short-period variables have a mean variation of 1 magnitude, while the variation of the long-period class amounts to about 4·0 magnitudes. Reference is made to the possible connection of distinctive colours to the various types of variables.

The catalogue gives particulars of ninety-three variables, copious notes being included in explanation of individual stars.

ON A SOLAR CALORIMETER DEPENDING ON THE RATE OF GENERATION OF STEAM.

THIS instrument was shortly described in a note[1] which was communicated to the Royal Society of Edinburgh in July, 1882, and it has been fully described and figured in a paper[2] read before the Philosophical Society of Cambridge in December, 1900. In this paper the results obtained in Egypt in 1882 are detailed and discussed.

My object in designing the instrument and in taking it to Egypt was to find out for myself the amount of heat which can be actually collected from the sun's rays at or near the sea-level under favourable conditions. In such circumstances this amount must fall on land and sea alike, and it is the energy of this radiation which maintains the terrestrial economy.

The instrument measures the sun's heat in the same way as the calorific value of other fuels is commonly measured, namely, by the quantity of boiling water which a given quantity of it can transform into steam of the same temperature in a given time. The quantity of the sun's radiation used is measured by the capacity of the reflector which collects it. The reflector concentrates it on the boiler, which is a silver tube with blackened surface, placed in the focus of the reflector. Some radiation is necessarily lost at the reflector and some at the surface of the boiler, because perfect reflectors and perfect absorbers do not exist; but, when the distillation has been started and is in full running, the whole of the heat which penetrates the boiler is used in transforming water into steam, which is retransformed into water in the condenser and measured in the receiver. A portion of the heat of condensation is utilised in raising the feed water to the boiling temperature before entering the boiler.

The details of construction and the dimensions are fully set forth in the paper printed in the *Proceedings* of the Cambridge Philosophical Society. It will be sufficient here to give a brief summary. Fig. 1 shows a general view of the calorimeter mounted equatorially on a tripod. Fig. 2 shows the calorimeter in section. The sun's rays are collected by the reflector $B_1 B_2 B_3 B_4$, which consists of three conical mirrors, $B_1 B_4$, $B_2 B_3$ and $B_3 B_4$, so constructed that rays of light, parallel to the axis of the instrument O P, falling upon these mirrors are all reflected upon the length A B of the axis. A B is the *focal line* of the reflector. The mirrors are carried by arms, as shown, which are attached to the central tube C K. This tube, which is twelve inches long and has a diameter of two inches, is the condenser. It is connected by an india-rubber tube with the glass funnel Z, through which it is filled and by means of which the height of the water in the upper and narrower tube C A can be regulated. The portion A B of this tube is the boiler. It is of silver, blackened outside, and has a circumference of 37 millimetres. When the instrument is pointed to the sun all the rays which strike the mirrors are reflected upon this surface, which has an area of 18·8 square centimetres. The effective collecting area of the reflector is 904 square centimetres, so that the rays are concentrated 48 fold. The glass funnel Z is set so that the level of the water inside the calorimeter stands somewhere between E and F. F G H is a glass tube or dome which performs the functions of a water-gauge, a steam space and a means of watching the distilling operation with a view to being perfectly assured that there is no priming. The tube G L in the

[1] *Proceedings* of the Royal Society of Edinburgh, 1882, xi. 827.

[2] On a solar calorimeter used in Egypt at the total solar eclipse in 1882. By J. Y. Buchanan, F.R.S. *Proceedings* of the Cambridge Philosophical Society (1900), xi. pp. 37, 74.

axis of the instrument is the steam delivery tube. When everything was cold and the sun's rays were concentrated by the reflector on the tube A B, the water boiled in forty seconds. The steam rises in the glass dome, from which it finds exit through the tube G L. Condensation begins so soon as the steam has passed below the point B, and the water produced is collected at L in a graduated tube. After the distillation has been running for a certain time a considerable quantity of very hot water is collected at the upper part of the condenser, and it slowly rises through the narrow annular space B C to replace the water removed from the boiler by evaporation. The boiler is thus fed with water at the boiling temperature, and when the calorimeter has settled down into steady working, the whole of the heat which reaches the water from the sun is used in *transforming water at its boiling point into steam of the same temperature.* It is essential that the distillation be kept running continuously. If the meteorological conditions are such that the boiling is interrupted, then it is of no use making observations at all.

Locality.—Sohag, where the observations were made, lies on the left bank of the Nile, in lat. 26° 37′ N. The expedition

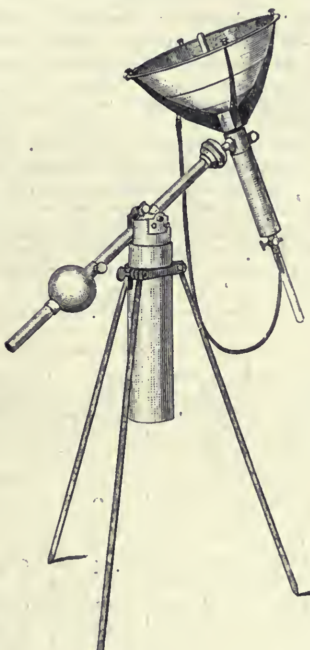

FIG. 1.

arrived there on May 8, 1882, and I was able to begin work on the 11th. As the instrument was new in every way, the work of the first few days was directed towards learning the manipulations and finding out and rectifying defects. Improvements of one kind or another were made every day up to the 15th. On the 16th, 17th and 18th experiments were carried out with the instrument in best working order, and under very favourable conditions. The sun's declination was 19° 22′ on the 17th, so that the mean meridian altitude during the three days was 82° 45′, corresponding to a zenith distance of 7° 15′. The following table gives the sun's zenith distance, as taken from the globe, at every half hour from noon to ± 4 hours, apparent time:—

Hours	0	0·5	1	1·5	2	2·5	3	3·5	4
⊙'s zenith distance	7°·25	10°·5	16°	22°·5	29°	36°	42°	49°	55°·5

The useful time for observation is from 9 a.m. to 3 p.m.

The principal object of the experiments was to ascertain the *maximum* rate of distillation under the most favourable circumstances. This occurred during the forenoon of May 18, when the meteorological conditions were as favourable as they could be. The sun shone steadily in a cloudless sky, and the air was motionless. The shade temperature reached 40°·5 C. in the course of the day.

Between 11h. 35m. 40s. and 11h. 39m. a.m., 5 cubic centimetres of water were distilled, being at the mean rate of 1·501 c.c. per minute at 11h. 37m. 20s. a.m. As the collecting area of the reflector is 904 square centimetres, this corresponds to 16·60 c.c. distilled per minute per square metre. At 11.37 a.m. the sun's zenith distance was 20°. Therefore we know that the sun's perpendicular rays, as received at or near the sea-level, have a heating effect sufficient to evaporate *more* than 16·6 c.c. of water per square metre per minute. Correcting this value for the obliquity of the sun's rays, by the method which shall be indicated presently, it becomes 17·04 c.c. per square metre per minute.

If we take the cubic centimetre of water to weigh one gramme and the latent heat of steam at 100° C. to be 535 gramme-degrees (grs.° C.), the evaporation of 17·04 c.c. water requires 9116 grs.° C. of heat; and this is the amount of heat in ordinary units per square metre per minute which can be collected from the rays of the vertical sun at the sea-level, and can be there utilised. Further, 9116 grs.° C. of heat are equivalent to 3875

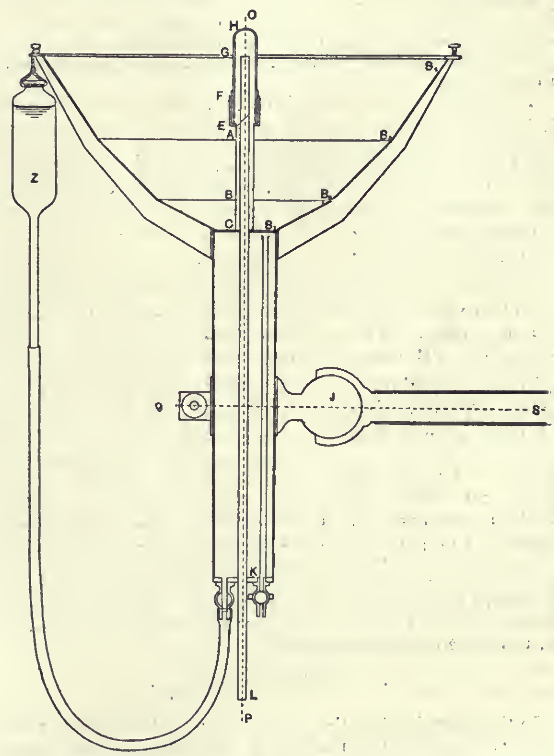

FIG. 2.

kilogramme-metres (kg.m.) of work, so that the working value of the sun's rays as collected by our calorimeter is 3875 kg.m. per minute, or 0·87 horse-power per square metre. No allowance has been made for instrumental imperfections. They certainly exist, but I do not think that more than ten per cent. need be allowed for them. If, however, we increase the working value of the sun's rays from 0·87 to 1·0 horse-power, the allowance is certainly sufficient; and this is probably very close to the true heating value of the sun's rays as they reach the sea-level. Taking the earth's mean distance from the sun's centre to be 212 times the radius of the sun, the radiation emitted by one square metre of the sun's surface is spread over, in round numbers, 45,000 square metres of the earth's surface. Therefore the intensity of the radiation of the sun's surface is equivalent to at least 45,000 horse-power per square metre. This figure, especially when used in connection with so very small a surface as one square metre, conveys no definite idea to the mind. The following consideration may assist in giving definition to our conception. The specific gravity of solid iron at ordinary terrestrial temperatures is about 7·5; therefore one cubic metre of it weighs at the earth's surface 7500 kilogrammes. Taking the force of solar gravity at the sun's surface to be twenty-eight times that

of terrestrial gravity at the earth's surface, one cubic metre of cold solid iron on the sun's surface would exercise a pressure of 210,000 kilogrammes. To lift this mass through one kilometre against solar gravity would involve the expenditure of 210×10^6 kg.m. of work: and if this amount of work were done in one minute, the engine employed would have to develop 46,667 horse-power.

Further, the heat which is equivalent to 210×10^6 kg.m. of work is 494,100 kilogramme-degrees (Kg.° C.). When iron is burned in oxygen so as to form the magnetic oxide, the heat evolved is given by the thermochemical equation

$$Fe_3 + O_4 = Fe_3O_4 + 264{\cdot}7 \text{ Kg.}^\circ \text{ C.}$$

Using this constant, we find that the mass of iron which by its combustion would furnish the above amount of heat, would weigh on the surface of the earth 313·5 kilogrammes, and would occupy a volume of 0·0418 cubic metre, or 1 square metre × 4·18 centimetres. Therefore the heat required could be produced by burning 4·18 centimetres of liquid iron on a hearth of 1 square metre per minute. With a supply of oxygen of high tension this would not seem to be an insurmountable task. This is put forward only as an illustration, and in no way as an explanation of the source of the heat of the sun.

With this caution, however, I should like to call attention to a coincidence.

The specific heat of Fe_3O_4 is 0·1678, and its molecular weight 232, whence the water value of the gr. molecule is 38·93 grs. The molecular heat of combination is 264,700 grs.° C. Dividing this number by 38·93 we get 6800° C. as the temperature of the Fe_3O_4 produced. Adding 273, we have 7073° C. as the absolute temperature which may be produced. In a recent work[1] Scheiner gives 7010° C. as the most probable effective absolute temperature of the sun.

Whilst the maximum value recorded by the calorimeter is the most important for the determination of the sun's heating power, the other values obtained are of use for testing the working of the instrument. The principal disturbing element is wind. During the forenoon of the 18th there was an almost complete absence of wind. We take the observations of that forenoon, neglecting those that show a diminution of intensity as noon is approached, because the sun's heating power cannot diminish as noon is approached. They are collected in the following table. In the first column *a* is the mean time corresponding to the mean rate of distillation under *d*. Under *b* we have the sun's zenith distance at this time, and under *c* the secant of this angle, so that $c = \sec b$. Under *d* are the mean rates of distillation, in c.c. per minute, for quantities of 20 c.c. collected. Under *e* are these rates reduced to their value per square metre per minute, $e = 11{\cdot}06\,d$. Under *f* we have the values of *e* corrected for the obliquity of the sun's rays. For this purpose the formula given by Herschel in his "Meteorology" is used.[2] It is, using the letters in our table,

$$e = f(\tfrac{3}{4})^c \text{ whence } f = \frac{e}{(\frac{3}{4})^c}.$$

In this equation $\frac{3}{4}$ is the transmission coefficient of the atmosphere; therefore *f* is really the solar constant expressed in cubic centimetres water evaporated per square metre per minute. Under *g* it is given in grs.° C. per square centimetre per minute, whence $g = 0{\cdot}0535f$. As we have assumed $\frac{3}{4}$ to be the transmission coefficient of the atmosphere, and have found the vertical intensity of the sun's rays outside of the atmosphere, we obtain at once its intensity at the sea-level $h = \frac{3}{4}f$. This is expressed in cubic centimetres water evaporated per square metre per minute, and it is practically unaffected by the value which we accept as the transmission coefficient of the atmosphere.

[1] "Strahlung und Temperatur der Sonne." Von Dr. J. Scheiner, Leipzig, 1899, p. 39.

[2] "Meteorology," by Sir John Herschel, Bart., Edinburgh, 1861, p. 10.

The figures in this table show that the values of the heating effect of the rays of the vertical sun, deduced from observations made when the sun was at zenith distances ranging between 10° and 44°, are practically identical. This affords very strong evidence that the calorimeter is a trustworthy instrument.

Reverting to our maximum value with an allowance for instrumental imperfection, if we take one horse-power per square metre as the intensity of the rays of the vertical sun at the sea-level, their intensity outside of the atmosphere is 1·5 horse-power per square metre, using Herschel's value for the transmission coefficient. This is equivalent to 15,882 grs.° C. per square metre, or 1·588 grs.° C. per square centimetre per minute. In round numbers we obtain 1·6 for the value of the solar constant. While it is possible that this value may be a little too low, reasons are given in the paper for believing that the values commonly received, which lie between 3 and 5 grs.° C. per square centimetre per minute, are much exaggerated.

Observations made during the Eclipse on the morning of May 17, 1882.

The calorimeter was directed to the sun as soon as after totality as possible. At 8h. 34m. the sun was totally eclipsed; at 8.51 the calorimeter was directed to the sun, but no boiling took place. At 8.58 the water began to "sing"; at 9.1 it boiled; at 9.3 it was boiling briskly, but it was not till 9.17 that the first drop of distillate fell into the receiver. By 9.19·5 1 c.c. had passed, and between 9.21 and 9.29·5 5 c.c. passed.

The observations made at this time are collected in the following table. In the first column is the apparent solar time of each observation, in the second column is the volume of distillate collected at that time, in the third column is the mean date of collecting each portion, in the fourth column is the date stated in minutes after totality, in the fifth column is the average rate of distillation in c.c.'s per minute during the interval, and in the sixth column is the percentage of the sun's disc exposed.

Apparent solar time, A.M.	Cubic centims. collected	Mean date and interval, A.M.	Minutes from totality	Rate of distillation	Amount of sun's surface exposed
h. m. s.		h. m. s.		c.c. per min.	
8 34 0	0		0		0·000
9 1 0	0		27		0·329
9 17 0	0				
9 19 30	1	9 18 15	44	0·400	0·509
9 21 0	0				
9 29 30	5	9 25 15	51	0·589	0·609
9 36 5	10	9 32 47	58·5	0·759	0·703
9 40 55	15				
9 45 45	20	9 40 55	67	1·034	0·788
9 47 0	0				
9 51 15	5				
9 56 0	10	9 51 30	77·5	1·111	0·864
9 59 50	15				
10 4 5	20	10 0 0	86	1·237	0·924
10 5 0	0				
10 8 52	5				
10 14 35	11	10 9 45	96	1·146	0·987
10 18 40	16				
10 22 20	20	10 18 30	104·5	1·161	1·000

From this table we see that when distillation has begun, it increases at a much greater rate than the exposed sun's surface. This must be so in the early stages, because we see that it is not till 26 minutes after totality, and when already 33 per cent. of the sun's surface has been uncovered, that the water in the boiler boils, and it takes 16 minutes more before any distillate is collected. Even when 50 per cent. of the sun is exposed, the rate of distillation is only 0·4 c.c. per minute. After this more weight may be attached to the observations, but their numerical significance is not great. Still, they show that useful information could be obtained by arranging for making trustworthy observations during the progress of an eclipse.

In the case of a total eclipse there must be an interval during which the sun cannot keep steam, however large the reflector

may be and however great its concentrating power may be. We have seen that when exposed cold as soon as possible after the total phase of the eclipse, it was twenty-seven minutes after totality before the water boiled. One-third of the sun was then uncovered. It is, therefore, reasonable to suppose that, if the eclipse had happened at noon, so that the first half of it could have been utilised as well as the second half, the sun would have kept steam in the calorimeter, and it would have continued to distil until two-thirds of the sun's surface had been obscured. Then distillation, if it did not cease, would become so slow that its rate would have no value, and fifty-four minutes would elapse before one-third of the sun would again be uncovered, during which the calorimeter would get cold. During this interval *steam must be kept artificially*. This is very easy. The glass tube which forms the steam dome is attached to a metal collar which screws down on a washer. It can, therefore, be easily detached. If, then, the steam tube of the calorimeter be connected by means of an india-rubber tube with a flask in which water is kept boiling, steam can be passed through the calorimeter at the normal rate until it is judged suitable to expose it again to the sun. There is no difficulty about this.

Although quite insignificant as a natural phenomenon, an annular eclipse is better for calorimetric experiments than a total one. On November 11, 1901, there will be an annular eclipse visible in Ceylon. The annular phase will last over ten minutes, and, at its greatest, 0·875 of the sun's disc will be covered. It is fairly certain that the calorimeter used in 1882 would not keep steam through this phase, but a larger reflector might be used. It would be worth while to have a reflector of such a size that steam would certainly be kept through the whole eclipse, especially during the annular phase, when all the radiation is from the peripheral region. J. Y. BUCHANAN.

THE MINING STATISTICS OF THE WORLD.

It is impossible to imagine a more concise, more intelligible, or more inexpensive collection of comparative mineral statistics than is contained in the General Report on Mines and Quarries prepared by Dr. C. Le Neve Foster for the Home Office, and it would be difficult to find an editor possessing in a more marked degree the requisite technical knowledge, literary skill and critical acumen for the difficult task of abstracting and collating the heterogeneous official mineral statistics of foreign countries and of rendering them intelligible to the general reader. In many countries the statistics published are imperfect or antiquated. Nevertheless, as regards output, Dr. Le Neve Foster has succeeded in getting together a mass of figures which, in the case of the more important minerals, may certainly be regarded as trustworthy. He has brought into one focus a representation of the present position of the mining industries of the world, and has thus rendered it possible to comprehend the enormous development that has taken place within recent years. The statistics given are of the greatest importance from a commercial point of view. In the United Kingdom alone the value of the minerals raised in 1899 was 97,470,000*l.*, and the vast sums representing British capital invested in mines in all parts of the world will be readily appreciated. Some indication of the remarkable strides made by the mining industry during the past ten years is afforded by the following comparison of the world's output of metals in 1889 and in 1899:—

	1889 Metric Tons	1899 Metric Tons
Iron	26,000,000	39,136,000
Gold	182	477
Silver	3,900	5,445
Copper	266,000	507,000
Lead	549,000	676,000
Zinc	335,000	511,000
Tin	55,000	74,000

In 1899 the world produced 723,239,000 tons of coal, 16,755,000 tons of petroleum, and 12,890,000 tons of salt. Nearly one-third of the coal supply was furnished by the British Empire. The United States supplied nearly another third, and Germany more than a sixth. The remainder was contributed mainly by Austria-Hungary, France and Belgium. The coal production of the principal countries was as follows:—

	Metric tons.
United States	230,254,000
United Kingdom	223,627,000
German Empire	135,824,000
Austria-Hungary	37,562,000
France	31,218,000
Belgium	22,072,000
Japan	6,761,000
India	5,016,000
New South Wales	4,671,000
Canada	4,142,000
Spain	2,671,000
Transvaal	1,938,000

In 1889 the United States for the first time outstripped Great Britain as a coal-producing country. In twelve months the British increase was 18,000,000 tons, but that of the United States was 30,000,000 tons. This enormous increase is undoubtedly due to the extended use of coal-cutting machinery. In the United States 23 per cent. of the total output of coal was mined by machinery. Only a little more than 1½ per cent. of the output was so obtained in Great Britain. The path of progress is, therefore, clearly indicated to British colliery owners.

As gold producers the British possessions take the first place, and, thanks to the increased output of Canada and of Western Australia, the British Empire reached a total of 5,475,000 ounces, or more than one-third of the world's supply. One-fourth of the world's salt, and more than half of the tin, are produced by the British Empire. On the other hand, the production of copper, lead, petroleum, silver and zinc is small in comparison with the world's output. The magnitude of the petroleum industry is surprising in view of the fact that its growth has been within the last half of the nineteenth century. The chief producing countries were:—Russia with 8,340,000 tons, the United States with 7,247,000 tons, Austria-Hungary with 325,000 tons, Roumania with 313,000 tons, and the Dutch East Indies with 217,000 tons. The United States has had to cede to Russia the position it so long held as first in the production of petroleum.

In 1899 the Transvaal was the greatest gold-producing country of the world, the output representing a value of 16,273,000*l.* Owing to the war, detailed statistics for 1899 are not available. In Cape Colony the outbreak of the war in October caused a rapid decrease in the output of the coal mines, and eventually stopped nearly all of them. In Natal, again, coal-mining was interfered with, and no official report for 1899 has been received. In Rhodesia, on the other hand, gold-mining made remarkable progress. The output of gold was 65,304 ounces in 1899, whilst in the previous year it was 18,085 ounces. The mining prospects of the country are certainly very satisfactory, more especially as the search for coal is giving most promising results.

The copious references to original sources of information given by the editor in footnotes form a very valuable feature of the report. In this connection it is noticeable that in his capacity of juror at the Paris Exhibition Dr. Le Neve Foster has had access to numerous special reports which, but for his assiduity, would hardly have come to the knowledge of English engineers. The great development of the iron ore resources of Luxemburg during the last thirty-two years, for example, was clearly illustrated in a table shown at the Paris Exhibition. In 1868 the output of iron ore was 691,000 tons, whilst in 1899 it was 5,995,000 tons. At another place in the volume the latter figure is given as 6,014,000 tons, there being apparently a slight discrepancy between the figures obtained by the Home Department of the Grand Duchy and by the German Customs Union, of which Luxemburg forms part. The political classification of the various States is in several cases a matter of difficulty, and has been attended to by Dr. Le Neve Foster with scrupulous care. It is possible, however, that in dealing with Austria and Hungary under one heading, while Sweden and Norway are dealt with separately, he will cause offence to the ultra-patriotic Magyars. Since the compromise between the two States, renewable every ten years, was not renewed in 1897, the Union is merely personal through the Emperor and Apostolic King, and in order to make it evident that Hungary is not a vassal State, the official denomination of the Austro-Hungarian Monarchy is to be preferred to the term Austro-Hungarian Empire used in the report.

Although not so trustworthy as the figures relating to mineral output, the statistics of persons employed and of accidents in mines are quite as important. The number of persons employed at mineral workings in 1899 throughout the world amounted to 4,312,000, of which 1,635,000 were engaged in the British Empire. The United Kingdom headed the list with 862,000 persons. Then followed Germany with 527,000, the United States with 488,000, France with 302,000, Russia with 239,000, Austria-Hungary with 219,000, Belgium with 164,000, and Japan with 133,000. Prior to the war the late South African Republic employed 100,000 miners. It appears that the British Empire employs more than one-third of all the persons engaged in mining and quarrying in the world. It must, however, not be forgotten that published figures are far from being absolutely accurate, and those cited by Dr. Le Neve Foster are merely the best obtainable at the present time. As an example of inaccuracy, the official returns from Ceylon give 1,108,306 persons employed in 1898 in mining in that island. It is incredible that the mining industry of Ceylon, which is comparatively insignificant as regards output, should afford occupation to as many persons as are employed in mining in all the other countries of the British Empire put together. Such figures are utterly useless for calculating death rates, and have, consequently, been discarded. The standard adopted for death rates is the number of persons killed per 1000 employed, and a comparison of the figures in different countries affords a good idea of the relative safety of the miner's occupation. In Great Britain, in 1899, there were killed in coal mines 1·24, in other mines, 1·76, in quarries 1·19, and in all mines and quarries 1·26 per 1000 employed. For the British Empire the average was 1·27 for coal mines and 1·64 for metal mines, and for the world 1·83 for coal mines and 1·64 for gold mines. In foreign countries the average was 2·25 in coal mines. It is evident, therefore, mining is conducted in Great Britain with a far smaller risk of accident to the workers than in most other countries. This gratifying result is due in no small measure to the untiring efforts made to improve the conditions of mining by means of legislation and Government inspection.

BENNETT H. BROUGH.

THE MINERAL CONSTITUENTS OF DUST AND SOOT FROM VARIOUS SOURCES.[1]

NORDENSKJÖLD collected and described three different kinds of dust, one consisted of diatoms, a second of a siliceous and apparently felspathic sand, both from the surface of the ice in Greenland; while a third consisted of sooty-looking particles composed of elements invariably associated with iron meteorites and of uncommon occurrence in terrestrial matter, namely, besides metallic iron, cobalt, nickel, carbon, silicon and phosphorus. He concluded that it was meteoric matter showered down upon the earth, and that cosmic dust is falling imperceptibly and continually.

A great variety of mineral matters, including dust from various sources, having been examined spectrographically by the authors, they give an account of its composition. Specimens which fell from the clouds were compared with those from known terrestrial sources. The first comprised (1) solid matter forming the nuclei of hail-stones collected during a storm on April 14, 1897; (2) solid matter from hail and sleet collected during a heavy shower from 2.30 p m. to 3 o'clock on March 28, 1896; (3) pumice from the Krakatoa eruption of 1883. These were examined for Prof. J. P. O'Reilly, who had collected them. (4) Dust from a dish exposed on November 16 and 17, 1897, in the outskirts of Dublin; and other samples with a similar origin which had fallen into porcelain dishes placed on a grass-plat in a garden. Varieties of flue-dust, (4) from Crewe gas-works, (5) iron-works, (6) sulphuric acid works, and (7) copper-smelting works, (8) volcanic dust from three different sources, (9) soot from laundry, laboratory, kitchen and bedroom chimneys. Flue-dust is characterised by the larger proportions of lead, silver and copper than other varieties of dust and coal ashes contain. Nickel and manganese are notably present, but the most striking feature is the quantity of rubidium, gallium, indium and thallium in all samples. Volcanic dust shows the bands of lime and magnesia with strong spectra of the alkali metals, and these are evidently its leading basic constituents.

Soot is of variable composition, not so much with respect to the substances present as to the relative proportions of each in any two samples. Its larger proportion of lime distinguishes it from dust collected from the heavens. Nickel, manganese, copper, silver and lead are constant constituents. The presence of nickel is probably due to minute quantities of this element being disseminated in coal, which is first converted by the carbon monoxide produced in the fire into nickel tetracarbonyl, which is naturally volatile but subsequently becomes decomposed and nickel or nickel oxide is deposited.

Dust from the clouds, collected either by itself or in hail, snow, sleet or rain, exhibits a regularity in composition not seen in other varieties of dust. It contains, apparently, the same proportions of iron, nickel, calcium, copper, potassium and sodium. The chief difference occurs in dust suddenly precipitated in sleet, snow and hail, since lead is found in larger proportions in these, and particularly so in one specimen from sleet.

It is evident that the presence of nickel is not positive evidence that the dust from the clouds comes from other than a terrestrial source.

The dust which fell on November 16 and 17, 1897, with its similarity in composition to that of meteorites, its being attracted by the magnet and its appearance are quite in favour of its being of cosmic origin. On the other hand, in its composition it is unlike volcanic dust, flue-dust or soot.

[1] By Prof. W. N. Hartley, F.R.S., and Hugh Ramage. Abstract of a ead at a meeting of the Royal Society, February 21.

STUDIES IN VISUAL SENSATION.[1]

THE object of these studies is to frame if possible a scale of visual sensation analogous to, and in correlation with, a scale of physical luminosity. The method is the employment of rotating discs.

If a disc be divided into eleven concentric areas of equal width, of which the inner is all white and the outer all black, while the intervening areas have sectors giving a series of 10 per cent. increments of white, this gives on rotation a series of grey rings between the black and white; but they are of very unequal values for sensation. While the step from black to the darkest grey involves a large stride in sensation, seemingly almost half-way towards the white, that from white to the lightest grey is of no great amount.

A contrast effect is very noticeable. Each grey annulus, especially in the darker rings, is differentiated in sensation into a darker moiety where it adjoins a lighter ring, and a lighter moiety when it adjoins a darker ring. But although contrast introduces a factor which somewhat distracts the judgment, the disturbance is not sufficient to invalidate the conclusion that equal, or approximately equal, increments of stimulus produce increments of brightness which differ widely in value.

By the use of slit discs on Maxwell's method the proportions of white stimulus may be so adjusted as to give, say, three rings intervening between white and black which do give approximately equal sensation steps. It is somewhat difficult, however, to estimate their value, and contrast again introduces a disturbing element. We obtain only a first approximation to a scale of sensation. Taking the black employed (admittedly only a very dark grey and not an absolute black) as a zero, and calling the value of the white 100 per cent., both for sensation and stimulus, we have, on the arbitrary scale thus formed, the following percentages:—

	Sensation.		Stimulus.	
	Increment.	Sum.	Increment.	Sum.
Black ring	0	0	0	0
Dark grey	25	25	6·5	6·5
Mid grey	25	50	13·5	20
Light grey	25	75	27	47
White ring	25	100	53	100

Here the equal increments of sensation are correlated with increments of stimulus very nearly in geometrical progression.

By interpolation a smoothed curve can be drawn through the observed mid-point of 20 per cent. stimulus and translated on to a disc. But this does not give a smooth increase of sensation from black to white through intervening greys. The value of the mid-point is too high.

Experiments with smoothed curves show that a mid-point of

[1] Abstract of the Croonian Lecture delivered at the Royal Society on March 21 by Principal C. Lloyd Morgan, F.R.S.

12 per cent. gives an approximately even passage from black into white.

The discrepancy between the ring-grading and the smooth shading is shown to be probably due to the contrast effects before mentioned, of which a rough quantitative estimate can be given.

The curve through ·12 per cent. mid-point, with equal increments of sensation correlated with increments of sensation in geometrical progression, is accepted as affording an arbitrary and empirical scale for increase of brightness due to increase in physical luminosity.

Colours are dealt with and even shading is obtained from black into blue, and into red, orange, &c.; white into similar colours, and one colour into another—for example, red into blue through intervening shades of purple.

The luminosity of these colours is determined in terms of the arbitrary scale on Sir Wm. Abney's method; and the results, as deduced from the empirical curve, are compared with those directly observed by the method of shading in rotating discs.

For comparison, the results are given in terms of the mid-points of curves analogous to that for the shading of black into white:—

Mid-point Percentages.

	Deduced from luminosity.	Observed by method of shading.
Yellow on black	13·8 per cent.	13·5 per cent.
Orange „	18·6 „	18·0 „
Light blue „	19·7 „	19·0 „
Red „	23·6 „	23·0 „
Full blue „	29·5 „	28·0 „
White on full blue	24·7 „	25·0 „
„ red	30·6 „	30·0 „
Orange on full blue	35·4 „	36·0 „
Yellow on light blue	39·1 „	40·0 „
Red on full blue	43·0 „	44·0 „

If these results be accepted as giving a sufficiently close agreement, it follows, first, that for colour shading the percentages of stimulus required are dependent on the luminosity of the colours employed; and, secondly, that all the data obtained by the method of shading can be plotted on a single curve which exhibits the relation of stimulus to sensation in visual impressions.

If we assume that the black on the arbitrary scale has a value of 1·87474, and if this amount be added to the stimuli throughout the scale, so that the white becomes 101·87474, the mid-point 13·87474, and so on, the scale becomes, so far as stimulus is concerned, an absolute scale. And on this absolute scale of stimulus, the sensations, plus some undetermined constant, form an arithmetical series, while the stimuli which are in relation to them form a geometrical series. In other words, the addition of this constant to the summed increments of stimulus at any stage of the scale causes these summed increments to fall into line as the terms of a geometrical progression. The stimulus value of the mid-point on the absolute scale is the geometrical mean between the values of the extremers on the same scale. *On this assumption*, therefore, and *between these limits*, Weber's Law and Fechner's expression of it hold good.

Its validity beyond these limits is questionable. Dr. Waller has shown good reasons for believing that near the threshold of sensation the completed curve shows change of sign, and becomes sigmoidal. Apart from the evidence he adduces, some such assumption seems to be well nigh necessary if we are to attempt to give a complete curve, which, near the threshold of sensation, does not land us in the maze of difficulties arising from the asymptotic character of a wholly logarithmic curve.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

DR. J. J. SUDBOROUGH, senior lecturer and demonstrator in chemistry of Nottingham University College, has been appointed professor of chemistry at the University College of Wales, Aberystwith.

RECENT gifts in aid of the funds of the McGill University, Montreal, amount to more than 42,000*l*. Of this sum, nearly one-third was provided by the chairman, Sir William C. Macdonald, who has already given over half a million sterling to the same institution. As the development of the University has recently been mainly on the lines of applied science and medicine, it is the faculty of arts which will mainly benefit by this new donation.

IN the Court of Appeal, on Monday, it was decided that School Boards cannot provide out of the rates for instruction in subjects prescribed by the Department of Science and Art, either in day schools or in evening continuation schools. It is thus declared illegal for a School Board to expend money out of a local rate for any purpose other than elementary education. In schools in which instruction is given in subjects such as those in the Science and Art Directory any assistance afforded to them must come from funds other than those provided by the rate-payers for primary education. As many School Boards have been providing instruction of this kind, it is evident that the decision accentuates the urgent need of an authority to describe the powers of the various bodies concerned with primary and secondary education.

THE Association of American Universities recently met at Chicago and discussed, among other topics, (1) inter-university migration of graduate students; (2) fellowship; and, (3) the examination for the degree of doctor of philosophy. From a report in *Science* we learn that with regard to the first topic it was considered desirable to promote by all possible means the inter-university migration of graduate students, to the end that they may come under the guidance of teachers of varying points of view, and so may receive the broadest possible introduction to their chosen field of study. As regards the question of fellowships, the opinion was expressed that it would be advisable to make some of the fellowships distinctly research fellowships, to be awarded only to students who had already taken the degree of doctor of philosophy, and who had, therefore, received their academic equipment for their life work. In discussing the best type of examination for the doctor's degree, it was held very emphatically that the practice which is growing up in American universities, especially in some of the departments dealing with natural science subjects, of permitting the candidate to pass his examination course by course, as is usual in undergraduate instruction, is a pernicious one, and one which stands in the way of the attainment of the best and broadest scholarship. It was held that the examination for the doctor's degree should, in all cases, be upon subjects and not upon courses of instruction, the underlying principle being that the courses of instruction which a graduate student attends are but a small part of the work which he is supposed to do in order to prepare himself for his examination.

MR. ANDREW CARNEGIE has presented to the Iron and Steel Institute thirty-two 1000-dollar Pittsburg, Bessemer and Lake Erie Railroad Company 5 per cent. debenture bonds, the income derived from which will be applied to awarding annually one or more research scholarships of such value as may appear expedient to the council of the Institute. The awards will be made on the recommendation of the council irrespectively of sex or nationality. Candidates, however, must be under thirty-five years of age, and application must be made on a special form to the secretary of the Institute before the end of April in every year. The scholarships will be tenable for one year, but the council will be at liberty to renew them for a further period if thought desirable instead of proceeding to new elections. The object of this scheme of scholarships is to enable students who have passed through a college curriculum, or have been trained in industrial establishments, to conduct researches in the metallurgy of iron and steel and allied subjects, with the view of aiding its advance or its application to industry. It is suggested that the National Physical Laboratory—on the governing body of which the Iron and Steel Institute is represented—would for many reasons be a very suitable establishment in which such researches could be carried out. There is, however, no restriction as to the place of research that may be selected, whether University, technical school, or works, the only absolute condition being that it shall be properly equipped for the prosecution of metallurgical investigations. The results of the researches are to be communicated to the Iron and Steel Institute in the form of a paper to be submitted to the annual general meeting of members. If the paper appears to the council to be sufficiently meritorious, the author will be awarded the Andrew Carnegie gold medal.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, March 7.—"Some Physical Properties of Nitric Acid Solutions." By V. H. Veley, F.R.S., and J. J. Manley, Daubeny Curator, Magdalen College, Oxford.

In continuation of their former investigations, the authors have studied the densities with especial reference to the contractions per unit mass, and also the refractive indices. The various experimental and instrumental errors are fully discussed, as also the several effects likely to be produced by the various substances with which the acid solutions of necessity came into contact. The results obtained for the physical properties are given in series of tables and compared with those calculated from various equations for straight lines; these show that the physical properties are discontinuous at points corresponding very approximately to the concentrations required for simple molecular combinations only of nitric acid and water. In the case of the contractions the best defined points of discontinuity correspond to the composition of the hydrates with 14, 7, 4, 3, 1·5 and 1 molecular proportions of water; in the case of the refractive indices, the most marked points correspond to the 14, 7 and 1·5 hydrates; a remarkable discontinuity at 95-100 per cent. concentration was also observed. These points of discontinuity, though to some degree, yet to another degree are ideal in that within the limits of 1 to 2 per cent. in the vicinity of such points there is a transition stage.

The values for μ are further expressed in terms both of Gladstone and Dale's and of Lorentz's formula, and it is shown that the values in neither case are constant, but decrease with increase of concentrations.

Anthropological Institute, March 12.—Prof. Haddon, F.R.S., in the chair.—Prof. Victor Horsley exhibited some trephined skulls from New Britain, and read a communication by Rev. J. A. Crump describing the methods employed by the natives and the objects aimed at. The operator is the medicine-man of the tribe, and he employs a flake of obsidian or piece of shell; with this he scrapes the exposed bone until a piece the size of half-a-crown is removed. As a rule the operation is resorted to in cases of fracture, and the mortality is about 80 per cent. In New Ireland, however, some forms of insanity, and even headache, are treated in the same way, and there are cases in which people have undergone the operation five times at various periods.—Mr. J. Gray read a paper on cephalometric instruments and cephalograms. An instrument was shown for taking head measurements, which was devised for field work and required no delicate adjustments. Two other instruments for obtaining diagrams of the contour of the head were also described, and head contours taken by them shown on the screen.—Prof. H. Louis described the "kingfisher" type of Malay kris, the handle of which resembles a kingfisher's head and beak; according to the Malay legend they were made in memory of a chief named Kingfisher, who invaded the peninsula from the Bugis Islands many centuries ago.

Zoological Society, March 19.—Dr. Henry Woodward, F.R.S., vice-president, in the chair.—Mr. Sclater exhibited and made remarks on some specimens of mammals from the Protectorate of Uganda recently received from Sir Harry Johnston, K.C.B. Amongst them were a skin and bones of a chimpanzee, which, so far as was known, was the only complete specimen of this ape that had reached this country from Eastern Africa. Other interesting objects in the collection were flat skins of two apparently new antelopes of the genera Cobus and Cephalophus. Mr. Sclater also laid upon the table a small case of Lepidoptera collected in St. Lucia, West Indies, by Major A. H. Cowie, R.E.—Mr. Tegetmeier exhibited a very fine head of the sable antelope (*Hippotragus niger*) from Barotseland.—A communication was read from Dr. G. Stewardson Brady which contained descriptions of a collection of Ostracoda belonging to the Zoological Museum of Copenhagen, most of the species represented in it being new to science. The collection was very varied in character, embracing examples of both marine and freshwater species from widely different localities.—Dr. C. I. Forsyth Major read a paper on *Lemur mongoz* and *Lemur rubriventer*, in which he pointed out that the species of Lemur which was generally called *Lemur mongoz* had absolutely nothing to do with the Linnean species of that name, which had been based on the description and figure of Edwards in his "Gleanings." The only ascertained localities in which the true *Lemur mongoz*, L., occurred were the neighbourhood of the Bembatoka Bay (N.W. coast of Madagascar) and the two islands Anjuan and Mohilla of the Comoro group. The earliest available name for the usually so-called *Lemur mongoz*—a very variable species, spread over a great part of Madagascar—seemed to be *Lemur fuscus*, E. Geoffr. The two species, as indeed were all the species of the genus, were easily distinguishable by the characters of their skulls.—Dr. Forsyth Major also showed that *Lemur rubriventer*, I. Geoffr. (of which *Prosimia rufipes*, Gray, was a synonym), was not, as had been supposed, the female form of *L. nigerrimus*, Scl., but a very well-marked species. A peculiar feature of the skull was a huge pneumatic cavity in the palatal, which invaded the whole bottom of the orbit.—A communication was read from Mr. P. Cameron containing an account of the Hymenoptera collected in New Britain by Dr. Arthur Willey. Owing to the fact of the locality having been but little explored previously, most of the specimens represented in the collection belonged to new species.—Mr. G. A. Boulenger, F.R.S., described four new species of freshwater fishes discovered by Mr. F. W. Styan, at Ningpo, China.—Mr. F. E. Beddard, F.R.S., read a note upon Garnett's Galago (*Galago garnetti*), in which he pointed out that a spiny structure, nearly similar to that previously described on the wrist of *Hapalemur griseus*, was also present on the hind foot of this animal.

Mineralogical Society, March 19.—Prof. A. H. Church, F.R.S., president, in the chair.—Mr. H. L. Bowman read a paper on the micas, tourmaline and associated minerals occurring in pegmatite at Haddam Neck, Connecticut. The occurrence resembles that at Auburn, Maine. A peculiar pink fibrous mineral surrounding prisms of lepidolite is shown to be a variety of muscovite.—Mr. G. F. Herbert Smith discussed crystals of calaverite from the Cripple Creek District, Colorado. They are triclinic, but pseudo-monoclinic owing to twinning about an axis parallel to the edge of the prism zone. The two individuals are interpenetrant with no apparent plane of separation. The crystals are also twinned in the ordinary way. Quantitative analyses made by Mr. G. T. Prior show that the material is nearly pure telluride of gold, $AuTe_2$, with only about 1 per cent. of silver.—Mr. W. Barlow exhibited models to show arrangements for the chemical atoms of crystals in harmony with the symmetry. The models are composed of closely-packed india-rubber balls of various sizes, each ball representing a single atom. Boracite, boric acid and cassiterite were dealt with. The structure assigned to boracite suggests an explanation of the peculiar dimorphism of this substance discovered by Mallard, and that representing cassiterite shows the twinning of this mineral.

Entomological Society, March 20.—Mr. G. H. Verrall, vice-president, in the chair.—Mr. C. J. Watkins sent for exhibition a series of larch twigs illustrating the winter condition of *Coleophora laricella*, the special feature being the manner in which the cases of the larvæ assimilated in colour with the bark of the larch.—Mr. G. B. Routledge exhibited a specimen of *Hydrilla palustris* taken on the wing by Mr. J. E. Thwaytes near Carlisle in 1899—the first male taken in that district. He also exhibited specimens of *Bembidium schuppeli*, a rare beetle captured on the banks of the river Irthing.—Mr. R. McLachlan exhibited Trichopterous larva-cases of the form known as "*Helicopsyche*" from the Prony River, New Caledonia, sent to him by Mr. J. J. Walker, R.N. They were large and remarkable for the size of the individual sand-grains of which they were built up. These sand-grains, Mr. Walker informs him, were water-worn particles of the heavier minerals of the river bed, such as chrome, nickel and iron ores. It is possible that similar cases were alluded to by Hagen in the *Stett. Entom. Zeitung*, 1864, p. 129, from the Munich Museum.—Mr. G. T. Porritt exhibited specimens of an almost black form of *Acronycta menyanthidis* from Skipwith Common, near Selby, and, for comparison, specimens from the moors near Huddersfield. The chief interest in the exhibit consisted in the fact that in both the districts where the melanic *menyanthidis* occurred, melanism was not a common feature: whereas in the Huddersfield district, where only the pale form of *menyanthidis* was taken, melanism was a conspicuous feature in many species, even in, and close to, the grounds, where only pale *menyanthidis* could be found.—Mr. H. W. Andrews exhibited a female specimen of *Amphidasys betularia*, with hind wings aborted and scarcely developed, taken at Paul's Cray, Kent, in May, 1896.—In connection with an announcement that the County Council had under consideration the feasibility of stocking the London parks with butterflies, Mr. H. Rowland-Brown stated that according to the

latest observations thirty-nine species of Rhopalocera were recorded within, roughly speaking, a ten mile metropolitan limit, but that of these he only knew of *Pieris rapae*, *P. napi*, *Vanessa atalanta*, *V. urticae*, and perhaps one or two others which could strictly speaking be said to inhabit the metropolis itself. Mr. A. J. Chitty said that *Pieris brassicae* had occurred, and that he thought *Vanessa polychloros* might be added to the list of those open to experiment. Mr. G. H. Verrall advocated the introduction of tropical and other foreign species in the great conservatories of Kew, where, without danger to the plants, they would be objects of great beauty and attractiveness, and Mr. Merrifield, while recognising the difficulties arising from soil, climate and surroundings, expressed his belief that certain hardy species would successfully resist their bird enemies.

Royal Microscopical Society, March 20.—Mr. A. D. Michael, vice-president, in the chair.—Messrs. Staley and Co. sent for exhibition a Bausch and Lomb Camera Lucida. It was described in the *Journal* of the Society last December, and is intended for reproducing an object diagrammatically, natural size.—Mr. E. M. Nelson read a paper on the working aperture of objectives for the microscope, in which he showed that in recording delicate observations it was advisable to state the precise ratio of the utilised diameter of the objective to the full available aperture. He then proceeded to explain the different methods by which this ratio, which he termed the working ratio, or W.R., could be measured. Dr. Tatham confirmed Mr. Nelson's views in regard to the necessity for recording the working aperture of objectives, and expressed his appreciation of the value of the methods proposed by the author for obtaining this measurement.—A paper, by Mr. H. G. Madan, on a method of increasing the stability of quinidine as a mounting material, was read by Mr. Nelson in the absence of the author. Mr. Madan found that by keeping quinidine heated to a certain temperature for a considerable time it was converted into colloid quinidine, which condition it had retained for a year; but whether the tendency to revert to the crystalline form was entirely overcome, time alone could show. Mr. Karop said of all media, quinidine, on the whole, was the best yet discovered for mounting diatoms, but it was very troublesome on account of its tendency to crystallisation. He hoped the material prepared as suggested by Mr. Madan would be marketed.—Mr. Rousselet read a paper on some of the rotifera of Natal, by Hon. Thos. Kirkman, illustrated by mounted specimens shown under microscopes. Mr. Rousselet had appended a technical description of *Pterodina trilobata*, one of the rotifers mentioned in the paper, a mounted one of which was among those exhibited; an excellent drawing of this rotifer, by Mr. Dixon-Nuttall, was also shown.—Mr. W. H. Merrett read a paper on the metallography of iron and steel, demonstrating the subject by the exhibition of a large number of lantern-slides of sections of different classes of these metals under various conditions of hardness, stress, &c. The methods by which these sections had been prepared and polished were also explained.

Royal Meteorological Society, March 20.—Mr. W. H. Dines, president, in the chair.—Dr. Hugh Robert Mill delivered a lantern lecture on climate and the effects of climate. He remarked that climatology is as much a branch of geography as of meteorology, in fact more, for it not only deals with the distribution of atmospheric conditions over the earth's surface, which is a geographical question in itself, but all the varieties of climate that give individuality to different countries are produced by the disturbing or controlling influence of land forms. After making a few remarks on the principles of scientific photography and also calling attention to spurious photographs, the lecturer proceeded to distinguish between "weather" and "climate." Weather is the condition of the atmosphere at any moment with regard to wind, warmth, cloud, electricity and precipitation; whilst climate may fairly be called the average weather of a place. Dr. Mill then exhibited on the screen a large number of photographs which he had himself taken in many countries, in order to illustrate the peculiarities of climates in which heat, cold, wind and rain respectively predominate, showing how the varying conditions of climate created by the greater land forms are responded to by the various adjustments of minor land-forms and of plants, and how they are taken advantage of by man.

CAMBRIDGE.

Philosophical Society, March 4.—Prof. Macalister, president, in the chair.—The ossification and varieties of the occipital bone, by Prof. Macalister. These deviations from the normal type, which occur in one out of every four skulls, may be divided into two great groups, (1) those depending on variations in the union of the five elements of the squama, supra-occipital, interparietal right and left and pre-interparietals right and left; (2) the second group consists of the variations due to the development of new centres of ossification in the lambdoid suture.—On the fifth book of Euclid's elements, by Dr. M. J. M. Hill.—Exhibition of Mr. Graham Kerr's method of reconstructing objects from thin sections, by Mr. J. S. Budgett.—Note on the colour vision of the Eskimo, by Mr. W. H. R. Rivers. Ten men and eight women from Labrador were tested with Holmgren's wools and found to have normal colour vision. In naming colours a limited number of terms were used which were extensively modified by suffixes to express differences of shade and tint of colour. The language was exceptional in possessing names for green and blue which were as definite as those for red and yellow, but resembled most other primitive languages in having no word for brown.—Note on the influence of external conditions on the spore-formation of *Acrospeira mirabilis* (Berk. and Br.), by Mr. R. H. Biffen. Chlamydospores of this fungus sown on pea extract gave rise to a sterile mycelium; on Klebs' solution and 5 per cent. glucose or cane sugar to numbers of intercalary sporangia; on beer-wort to sporangia and chlamydospores; on chestnut extract to endoconidia and chlamydospores—the former being in the greatest abundance when the extract was most dilute. Sowings of the spore-balls gave very similar results, the chlamydospores being replaced by spore-balls except in the case of beer-wort, where "ascogonia" were formed. Intermediate forms between the loose spiral "ascogonia" and the closely coiled helices of the spore-balls could be raised by transferring the mycelium from chestnut extract to beer-wort. Increasing the rate of transpiration caused the chlamydospores to become smooth and thick-walled, while diminishing it caused them to become smooth and thin-walled, instead of being rather thick and warted. The envelope of the spore-balls instead of being a single layer became several layers thick on checking the rate of transpiration.—On a reserve carbohydrate, which produces mannose, from the bulb of *Lilium*, by Mr. J. Parkin. Besides starch, the bulbs of several species of the genus *Lilium* examined contain another reserve-carbohydrate which exists as a sort of mucilage in the cell-sap. The sugar obtained from it by hydrolysis with weak acid is *mannose*.—Notes on new and interesting plants from the Malay Peninsula, by Mr. R. H. Yapp. The only partially explored mountain ranges of this region possess a very rich flora, unaffected by the presence of introduced species such as form a marked feature of the vegetation of the inhabited districts of the plains. A number of the specimens exhibited (which were chiefly collected on one of these mountains) are probably new, and belong to various natural orders, chiefly among the gamopetalous Dicotyledons. An interesting and little known fact is the storage of large quantities of naturally filtered water in the hollow internodes of several species of bamboo. The paper concluded with a brief account of two curious epiphytic ferns, whose fleshy stems are tunnelled by galleries inhabited by ants; forming, in fact, living ants' nests.—The prevention of malaria, by Dr. J. W. W. Stephens. This paper, after a brief historical account of the discovery and the investigation of the malarial parasite, described the researches of Dr. Christophers and the author on the disease in several localities on the west coast of Africa. The result of the work there done leaves no doubt that malaria is avoidable under the conditions of life in West Africa.—On the effects of a magnetic field on the resistance of thin metallic films, by J. Patterson. A. C. Longden, in the *Physical Review*, xi, 2, 40, described a method of making standard high resistances from thin films of metals deposited on glass by means of the kathode discharge. He has shown that the resistance of these films is much greater than that calculated from the ordinary specific resistance of the metal. The author has made experiments to determine what effect a magnetic field would have on the resistance of a film deposited in this manner from a bismuth kathode. The results obtained show that the change of resistance in the magnetic field is entirely different from that of ordinary bismuth. A film of cobalt $1\cdot4 \times 1\cdot3$ cm. with a resistance of $682\cdot2$ ohms was made, but no change in a field of 27,500 lines could be detected.—On the theory of electric conduction through thin metallic films, by Prof. J. J. Thomson. The author applies the theory, developed by him in a report to the International Congress of Physics at Paris in 1900, to the case of electric conduction through thin metallic films. He shows that when the thickness of the film

becomes comparable with the mean free path of the negatively electrified corpuscles, which on that theory are supposed to carry the electric current, the specific resistance of the substance forming the film will increase, and how it is possible from measurements of this increase to approximate to the mean free path of the corpuscles. It is also shown that the effect of a magnetic field on the resistance decreases with the thickness of the film.

Paris.

Academy of Sciences, March 25.—M. Fouqué in the chair.—On the Egyptian metals. The presence of platinum among the characters of a hieroglyphic inscription, by M. Berthelot. A metallic box, covered with inscriptions, and dating from about 700 B.C., had a portion of one of its characters made of an alloy of platinum. The specimen was too small for a complete analysis, but from its behaviour towards aqua regia it appeared to be a native platinum, possibly obtained from the alluvial deposits of Nubia or the upper regions of the Nile valley.—On the electrochemical relations of the allotropic states of metals, especially of silver, by M. Berthelot. The thermochemical behaviour of the different allotropic modifications of silver rendered it probable that a definite electromotive force could be observed in a cell containing the metal in two different states as electrodes. On experiment, this was found to be the case, the direction of the current agreeing with the thermal sign of the heats of transformation.—On secondary radio-activity, by M. Henri Becquerel. The radiation from a radium salt consists of three parts, the first, very easily absorbed, and capable of being deviated by a magnetic field; the second, similar in its nature to the kathode rays; and the third, very penetrating, but not capable of deviation by a magnet. Experiments are described showing the differences in the power of exciting secondary radiation possessed by these three classes of rays.—The origin of thermal sulphurous waters. Sulphosilicates and oxysulphides derived from natural silicates, by M. Armand Gautier. An experimental study of the mode of production of sulphurous waters. Granite and other igneous rocks, when finely powdered andtreated with water at 250°–300° C. give a liquid identical in character with ordinary thermo-sulphurous waters, although of greater concentration.—On some new derivatives of dimethylamido-benzoylbenzoic acid, by MM. A. Haller and A. Guyot.—A correction of a preceding communication by M. de Jonquieres.—On a formula of M. Fredholm, by M. G. Mittag-Leffler.—M. Sabatier was elected a correspondent for the Section of Chemistry in the place of M. Haller, named a member of the Academy, and Mr. Davidson a correspondent for the Section of Geography and Navigation, in the place of the late M. A. David.—On the general expression of the rational fraction approximating to $(1+x)^m$, by M. H. Padé.—On the formation of nodal lines of sand or dust, by M. C. Maltézos. A suggestion as to the cause of formation of small sandy hillocks on the sea shore.—The specific heat of a gaseous mixture of bodies in chemical equilibrium, by M. A. Ponsot.—The theory of the Wimshurst machine without sectors, by M. Bordier.—On the measurement of the period of the waves used in wireless telegraphy, by M. C. Tissot. The period of the oscillator was measured by the method devised by Fedderson and improved by Décombe. The periods measured were between $0{\cdot}6 \times 10^{-6}$ and $1{\cdot}8 \times 10^{-6}$.—The Ritchie telautograph, by M. Brauer. This apparatus transmits handwriting continuously without the use of clockwork.—On induced radio-activity and gases rendered active by radium, by MM. P. Curie and A. Debierne. It has been shown in a previous communication that the radio-activity induced by radium salts is effected through the intervening air. It is now found that the nature and the pressure of the gas are without effect upon the phenomenon, but that if a high vacuum is kept up the second body is not affected. On leaving the apparatus for some time, the secondary radio-activity is again observed, and if the gases evolved are again pumped off they are found to be extremely active in spite of their small mass. Their activity is so great that the glass tube containing them becomes fluorescent, and is visible in the dark.—The direct production of X-rays in air, by M. A. Nodon. Under the simultaneous action of ultra violet rays and an electric field X-rays may be produced without the use of a Crookes' tube.—A method for determining atomic weights founded upon the law of transparency of matter for the X-rays, and the application of this to the atomic weight of indium, by M. L. Benoist. The action of hydrogen upon realgar and the inverse reaction. The influence of pressure and temperature, by M. H. Pelabon.—The heat of formation of acetals compared with that of isomeric compounds, by M. Marcel Delépine.—On the acidimetric value of the monosubstituted benzoic acids, by M. G. Massol.—The passage from anisol to anisic acid by five successive oxidations, by M. J. Bougault.—On the law of the auxochromes, by M. P. Lemoult.—On naphthylol-naphthyl-oxynaphthylmethane, by M. R. Fosse.—The action of zinc upon the dibromide and diiodide of tetramethylene, by M. l'abbé J. Hamonet. On certain causes of variation in the quantity of gluten in wheat, by MM. Léo Vignon and F. Couturier.—Nervous conduction and muscular conduction of electrical stimuli, by M. Aug. Charpentier.—The variation of visual acuteness with lighting and adaptation; measurement of the migration of the pigment of the retina, by M. André Broca.—Curves of thermometric ascent, by M. S. Leduc.—On a parasite observed in the syphilitic, by M. H. Stassano.—On *Schistocerca americana*, its migration and area of geographical distribution, by M. J. Künckel d'Herculais.—The effects of lightning and "gélivure" upon trees, by MM. L. Ravaz and A. Bonnet. By an experimental study of the effects of electricity in motion upon the vine, the conclusion is drawn that the supposed disease of the vine known as "gélivure," and to which a microbial origin has been ascribed, is in reality due to the effects of lightning.—On the age of teschenite, by M. P. Choffat.

OSTWALD'S INORGANIC CHEMISTRY.

Grundlinien der anorganischen Chemie. Von W. Ostwald. Pp. xix+795. (Leipzig: W. Engelmann, 1900.)

NOTWITHSTANDING the great advances that have been made during the past generation in our theoretical knowledge regarding solutions and chemical equilibrium in general, elementary inorganic chemistry is taught to-day much in the same manner as it was in the early seventies. The ordinary student at the end of his junior course has a very hazy knowledge of chemical facts, and scarcely a trace of chemical common-sense; but to make up for these deficiencies he knows all about atoms and molecules. If he is asked how he would convert, say, cadmium sulphate into cadmium chloride, he will doubtfully reply, "Treat the cadmium sulphate with hydrochloric acid"—this because he knows no general principles concerning the facts of chemistry. If, on the other hand, he is asked why hydrogen and chlorine combine, he will probably answer with confidence somewhat in these terms: "They combine on account of the mutual attraction exercised by the chlorine and hydrogen atoms." He does not see that he is merely restating the fact in terms of an hypothesis, and that the question, in our present state of knowledge, has, properly speaking, no answer. The "heuristically" trained student has a better knowledge of certain facts, but he is equally ignorant of general principles, and equally unable to distinguish between what is fact and what is theory. To him, as to the other, chemical symbols, formulæ, and combining weights are part and parcel of the atomic theory, instead of a convenient method of expressing actual facts—a method, it is true, arrived at through the atomic theory, but a method which would persist though the atomic theory were abandoned to-morrow.

When such a student continues his course so far as to study modern theoretical and physical chemistry, he is loth to part with his old ideas, which enabled him to explain everything so beautifully (although in some mysterious, unfortunate way they never seemed to help him much when he was asked anything about facts), so that example and precept, experiment and lecture, do little to change his general attitude of mind towards the science.

All this is, of course, not the fault of the student, but the fault of the teacher, or rather of the text-books. The time that the student can devote to chemistry is, as a rule, so limited that some sort of text-book is indispensable, and this the teacher is obliged to follow more or less closely if he is to avoid confusing the student. Now of the elementary text-book of chemistry it may be said, "plus cela change, plus c'est la même chose;" the theory is almost invariably put before the student in its ancient form long before he needs to know anything about it, and long before he has a sufficient command of facts and principles to understand its derivation or appreciate its importance. The idea that a student must know the atomic theory and the means by which the present system of atomic weights has been arrived at, before he is taught the quantitative use of chemical symbols and equations, is pretty much on a par with the idea that a child must know the derivation of the alphabet from Egyptian hieroglyphics before he can be taught to read. From practical experience of teaching on both systems, the present writer can say that the student may be made to use symbols and formulæ very early in his course without attaching to them any theoretical significance whatever, and that he then uses them more carefully and correctly, because they represent to him definite quantities of definite materials, and not intangible atoms and molecules with which he can juggle at pleasure.

What is wanted, then, is an elementary text-book of chemistry developed from the outset in accordance with our modern theoretical knowledge. This want Prof. Ostwald's book is intended to supply, and the eminence of the author as investigator, writer and teacher is a sufficient guarantee of interesting and instructive reading.

So far as general arrangement is concerned, the book differs in no important respects from other text-books in the systematic description of the elements and their chief compounds. Physical and theoretical matters, however, are made subservient to the descriptive work, and are introduced as occasion requires. Thus the gas-laws come under the heading of oxygen; chemical forces, molecular weight, partial pressure, mass action, chemical equilibrium and catalysis, under hydrogen. The phase-rule is introduced in connection with water, to receive further exemplification under chlorine, sulphur, &c. In the same chapter are also discussed combining weights, the atomic and molecular theories and the law of reaction. Thermochemical equations are taken up in connection with hydrogen peroxide, photochemical action under chlorine, and electrolysis under hydrochloric acid. Valency appears halfway through the book in connection with phosphorus, and the last chapter of all deals with the choice of combining weights and the periodic system of the elements. Atoms and molecules are conspicuously absent.

These examples show the plan of treatment adopted; theory is throughout properly subordinated to fact and clearly distinguished from it.

As an instance of the modern aspect presented by the descriptive work in detail we may take the following section, which treats of the soluble salts of bismuth.

"*Bismuthion.*—Bismuth forms one sort of elementary ion, the trivalent bismuthion $Bi^{\cdots}$. This is almost the only ion derived from bismuth, for the tendency of this metal to form complex ions is extremely small, only a few complex organic ions containing bismuth being known.

"Bismuthion is colourless and forms an extremely feeble base with hydroxyl. The phenomenon of hydrolysis is consequently so pronounced in bismuth salts that it can be used as a characteristic test for them. As the basic compounds formed in this way are very slightly soluble in water, the bismuth salts can be precipitated by merely diluting them with water: on addition of acid the precipitate is re-dissolved.

"The best known bismuth salt is the *nitrate*, which is obtained in the form of the hydrated crystals, $Bi(NO_3)_3,5H_2O$, when the solution of bismuth in nitric acid is crystallised. When water is poured over these crystals, a snow-white crystalline powder of basic nitrate,

B B

$Bi(OH)_2NO_3$, separates out. . . . The nitric acid which is liberated passes into solution, so that a portion of the bismuth salt can remain dissolved. There is thus in the solution a chemical equilibrium with respect to the precipitate of basic salt, which is characterised by the concentration of the hydroxyl ion of the water being reduced, by the hydrogen ion of the free acid, to such a value as corresponds with the solubility-product of the basic salt. . . .

"When sodium thiosulphate is added to bismuth salts, a clear solution is obtained, which slowly decomposes with deposition of bismuth sulphide. The solution probably contains the sodium salt of a complex bismuth-thiosulphuric acid ; for on addition of potassium salts, a very slightly soluble precipitate of $K_3Bi(S_2O_3)_3+H_2O$ separates out, which may be looked upon as the potassium salt of this acid. Although it is probable that we are here dealing with a complex bismuth ion, accurate investigations are still wanting. It has been proposed to use the precipitate, which is of a yellow colour, as a means of detecting and precipitating potassium."

It seems almost a pity that the author, having before him the problem of presenting the material in such a new light, should not have seen fit to depart entirely from the traditional arrangement and set out the whole matter as he himself thought best. As he tells us in the preface, his choice was deliberate, and was no doubt well-considered, but the limitation in adhering to the historical treatment makes itself felt here and there throughout the book. It is new wine in old bottles.

No teacher of chemistry who takes the slightest interest in his profession or in his science can afford to leave this book unread. For the first time he has laid before him a presentation of the facts of elementary chemistry from the standpoint of modern theory, written as only Ostwald could have written it, and compelling attention, whether the reader agrees with the author or not. We understand that an English translation of the work has been undertaken, so that the student also will soon have it at his disposal. J. W.

AN AMERICAN ZOOLOGICAL TEXT-BOOK.

Text-Book of Vertebrate Zoology. By. J. S. Kingsley. Pp. viii + 439. Illustrated. (London: George Bell and Sons, 1900.) Price 12*s*. net.

AMONG the multitude of text-books upon various branches of zoology, or on zoology as a whole, that it has been our fortune to peruse, there are few, if any, of which we can say that they contain so much information in a comparatively small space as is the case with the one before us. Nor is this all ; whereas many works of a kindred nature are written in such an extremely abstruse style, and are so overloaded with technicalities as to be well nigh unreadable by any but the most thorough-going and uncompromising biological student, the style of the present volume is so easy, and the technical terms are so carefully explained, that a reader with little or no previous knowledge of anatomy or zoology would readily comprehend the nature of the structures described.

We refer in this connection to structures rather than to animals, because vertebrate morphology, based upon embryology, forms a leading feature of the book, the whole of the first part of which, comprising considerably more than half of the text, is devoted to this section of the subject. A systematic survey of all the leading groups of vertebrates constitutes the second moiety. And since there are few works known to us in which these two great divisions of the subject receive such an equal share of attention, on this ground alone Prof. Kingsley's treatise has a decided advantage over many of its fellows. Neither are his descriptions confined to the vertebrates of the present day, their extinct predecessors receiving a considerable share of attention. The work is, therefore, thoroughly comprehensive in its scope ; and is, in fact, for the most part exactly what such a treatise should be. Although it by no means does away with the need for text-books dealing with the palæontological aspect of the subject, it serves to indicate that the day when the zoologist and palæontologist worked on separate lines is gone for ever.

In a very large number of instances those whose studies are chiefly devoted to the anatomical and embryological side of zoology fail to keep themselves abreast of modern views in regard to systematic classification. But this cannot be laid to the charge of the author of the present volume, who has adopted a thoroughly modern and up-to-date system of classification, as is especially noticeable in his treatment of the fishes and of that group of vertebrates typified by the lampreys and hag-fishes, for which a popular collective title is at present a desideratum. The division of mammals into Prototheria and Eutheria alone is also a feature in accord with modern ideas.

Indeed, not only is Prof. Kingsley thoroughly up-to-date as regards classification, but in one instance, at least, he is ahead of contemporary opinion. We refer to his treatment of that difficult subject, the classification of birds. In his preface the author states that

"he has been unable to recognise in the so-called orders of ornithologists groups of birds of more than family rank, while their families are equivalent to genera in the other classes of vertebrates."

Accordingly, we find the class Aves divided into four ordinal groups only, namely, the (1) Saururæ, as represented by Archæopteryx ; (2) Odontormæ, typified by Ichthyornis ; (3) Odontholcæ, containing Hesperornis ; and (4) Eurhipiduræ, including all living birds. While our sympathies are to a very great extent on the side of the author in this matter, we are by no means prepared to go the whole way with him in this sweeping change, and venture to think that in this, as in most other matters, a *via media* is to be found. Moreover, we feel sure that if all existing birds are to be included in a single ordinal group, there is not the slightest justification for separating the cretaceous toothed birds (Hesperornis and Ichthyornis) as separate groups from the mere fact that they retain teeth, and in one instance biconcave vertebræ.

But all this is, to a great extent, a matter of detail, from which we return to the consideration of the work as a whole.

On one point, and on one point only, we take leave to consider that the author is unsound, and this is in connection with nomenclature. As he tells us in his preface, he refuses to change well-known generic names on the ground of priority, because "these are the names of morphological literature." If systematic zoologists have,

practically unanimously, come to the conclusion that Molge, and not Triton, is, for example, the proper title of the newts, and morphologists refuse to accept the change, we can only say so much the worse for the morphologists.

As we have already said, great credit is due to Prof. Kingsley for the attention he has devoted to the systematic part of his subject, as his own special studies are mainly directed to the anatomical and embryological aspects. But in these days it is well nigh impossible for a man to gain sufficient knowledge of a section of a subject with which he is not thoroughly familiar as to avoid mistakes when writing on it. And it would have been better for the reader had the author invoked the aid of a few specialists to revise the proofs of the systematic section of the work. Many awkward "misprints" and other errors would thereby have been avoided.

Restricting our criticism in this respect to the chapter on mammals, we may call attention to quite a number of "misprints" between pp. 395 and 399, most of which will be self-apparent to those conversant with the subject. One of the most serious is *Choeropus* for *Choeropsis* (p. 398); the one name indicating a marsupial and the other a hippopotamus!

But there are more serious errors still. On p. 399 we are told, for instance, that among the fossil genera of antelopes are Cosoryx, Tragelaphus and Antidorcas; the second being the title of the existing bushbucks, or harnessed antelopes, and the third that of the springbuck, which is alluded to on the same page as *Gazella euchore*, Cosoryx being also mentioned higher up on the same page as a deer! Neither is it correct to say that the American deer form only a sub-genus of Cervus. Again (p. 400), the domesticated Indian cattle are not the typical representatives of Bibos, and, indeed, do not belong to that group at all; while the statement (p. 401) that mastodons occur in Africa is, so far as we are aware, not founded upon fact. Were we disposed to dwell upon them, many other errors of a kindred nature might be pointed out, but we pass on to the illustrations.

Such of the latter as relate to anatomical structures and the development of the embryo are far the most satisfactory, and serve their purpose well, although frequently not of a very high class from an artistic point of view. But when we turn to the figures of birds and mammals we are surprised that any publisher could have been found willing to print such ghastly productions. Perhaps the very worst amongst a hopelessly bad lot are those of a bird of paradise on p. 350, and of the Sumatran rhinoceros on p. 355. Smudgy daubs is a mild way of describing them; and in the present age of cheap photographic illustration, the appearance of such ill-executed caricatures in any book is nothing short of a disgrace to all concerned in its production.

As regards the palæontological aspects of the subject, we think the author is to be congratulated on the manner in which it is treated. Of course there will be errors—and the omission of any mention of Ophthalmosaurus when noticing the Ichthyosauria (p. 313) is one—but they are few and far between; and in the main the relations of the extinct to the living types are well explained.

Apparently the book has been previously published in America, and its reproduction in this country may be taken as an indication that it has met with a favourable reception in the land of its birth. In spite of the blemishes to which we have referred (and they are, after all, not very great), we have no hesitation in saying that Prof. Kingsley's little volume is worthy of a hearty welcome on this side of the Atlantic on the part of both teachers and pupils.

R. L.

POPULAR BIBLICAL STUDIES.

The Social Life of the Hebrews. By the Rev. Edward Day. The Semitic Series. Pp. 255. (London: John C. Nimmo, 1901.)

THE present volume is the second of a series published under the editorship of Prof. Craig, of the University of Michigan, with the object of presenting "in popularly scientific form" the results of recent researches in Semitic fields. Prof. Craig has laid down for the last two years an ambitious programme of the work to be done in his series, and has announced the titles of no less than thirteen books of the series, but up to the present time only two of them have appeared. The first, by Prof. Sayce, was devoted to the social life of the Babylonians and Assyrians, and was reviewed by us last year; the second, which has appeared this year, and with which we are concerned, deals with the manners and customs of the ancient Hebrews. Mr. Day has undertaken a subject of great interest and, at the same time, one of great difficulty, inasmuch as almost the only sources accessible are limited to the Books of the Old Testament.

The publication of the late Prof. Robertson Smith's "Kinship and Marriage" and "Religion of the Semites" marked a great advance in Semitic learning, and since that time all writers on the customs of the Hebrews have been in great measure indebted to these books. In the first part of his book Mr. Day summarises to a certain extent the main features of Prof. Robertson Smith's work, though with some serious omissions. The Clan, the Family and Sacrifice are dealt with in three short chapters, none too much space for such important subjects, though doubtless enough for a popular work, while the remainder of the first part treats of the Hebrews during the period of the Judges. But no explanation at all has been given of the significance of circumcision, either as a sacrificial rite or from its connection with the *hôthên* "wife's father"; and though this may be due to the fact that the book is a popular work, yet, on the same grounds, a good deal of the matter relating to the licentious temple worship and similar customs might have been omitted. More, too, might have been said with advantage on the subject of totemism, which is but briefly discussed. The difficult subject of the Hebrew idea of the immortality of the soul has, perhaps, been reserved for another volume of the series, but we should have been glad to see a little more space devoted to the popular beliefs concerning Sheol, which is only spoken of once. Some reference, also, might have been made to the stress laid by the Hebrews on the importance of posterity and of prolonging the family name, which thereby acquired a terrestrial immortality. The chapter on the conception of Yahweh towards the

end of the book is better thought out, and will suffice for the needs of a popular work.

A characteristic of the book to which we must take serious exception is the frequent omission of references to passages on which Mr. Day bases his deductions. It is not enough to say "suicide was not discountenanced" (p. 172); if the statement is to be fully accredited, all the arguments, with chapter and verse, should be given in full. Moreover, we cannot congratulate Mr. Day on his attempt to provide us with a translation superior to that of the Authorised Version of the words *'ăsereth d'bhârîm*, or of I. Sam. ii. 8; the former he renders by "the Ten Words," a most infelicitous choice of the meanings of *dâbhâr* open to him, while the latter is translated "He taketh the needy from the city-dump" (p. 144); surely the old English word "dunghill" is not too outspoken for a popular book? Again, we must protest against such barbarisms as "pled" for "pleaded" (p. 28); "demonic" for "demoniac" (p. 56); "a few nearby men" (p. 62); and "he was the power back of nature" (p. 88); or such a hybrid as "David ben Jesse" (p. 63). We could wish, too, that Mr. Day's thirst after "local colour" (p. 225) had not led him to describe Samson as "being peculiarly susceptible to female charms" (p. 53); or his labours as "deeds of a purely personal character, in which a man of great strength got a little needed exercise, and at the same time revenged himself upon his personal enemies" (p. 66); or to refer to the rich of Samaria as "wealthy nabobs" (p. 102). The use of modern colloquialisms is unpardonable in all descriptions of Biblical events, challenging, as they do, the classic English of the Authorised Version. What can be said in defence of the following: "It is probable that the star-gazing of the society belles of Jerusalem, a Babylonian importation, was, like similar attempts to acclimate (!) foreign cults, in the nature of a fad, as was charioteering in the capital in the days of Absalom and Adonijah" (p. 116), or, "It was a long way . . . from the city-dump to a seat among the nobles of the land; but Yahweh knew the way" (p. 151)? Moreover, we are not by any means convinced that the "modern picnic" (p. 45) is the survival of the ancient sacrificial feast, even with the limitation "though seldom of such an exclusive character." It is a great pity that Mr. Day has thought fit to include such colloquialisms as the above in a work on which he has evidently spent time and care. We think, however, that he has not made the most of his opportunities.

OUR BOOK SHELF.

The Table of British Strata. By Dr. H. Woodward and Mr. H. B. Woodward. (London: Dulau and Co., 1901.)

THIS table will be welcome to students and teachers, for the existing charts are now quite out of date. To compile such is a laborious and somewhat thankless task, for it is impossible to please every one; indeed, the authors admit that in two respects, retaining the Permian in the Palæozoic and placing the Wealden in the Jurassic, they "seek to assert general rather than individual opinion." As to the former, the question seems to be largely one of locality; but in the latter we should have preferred the conservative side, at any rate till better cause is shown for the change; especially since it has led to the virtual suppression of the Neocomian as a system. For the same reason we are glad to see the Tremadoc group left in the Cambrian system. The latter they allow to be an important geological system, though we should have liked to see the alternative title, "Primordial Silurian," entirely suppressed, for it is commemorative of nothing less than an unwarrantable usurpation. The authors include the Solva Beds of St. Davids with the Menevian, which no doubt is justified by the presence of Paradoxides; but in that case too small a thickness is assigned to the system, for this addition would make it at St. Davids over two thousand feet. Remembering its importance on the Continent, we should have ventured to exalt Rhætic, thin as it may be in Britain, to the dignity of a system, and we think that over much importance is conceded to the subdivisions of the Tertiary series. Are the Thanet Sands or the Oldhaven Beds—not to mention others—more important than the Lower Calcareous Grit or the Stonesfield Slate? Yet we find the former among Formations and the latter in Subdivisions. Does not the statement that the glacial deposits contain only derived fossils beg a disputed question? It would be well to add "slates" to the economic products of Charnwood, for the "honestone," which is mentioned, is very local. A notable feature is the recognition as formation of Torridonian, Uriconian, Dalradian and Lewisian in the Archæan rocks, though some objection may be taken to the third name, on the ground that as originally defined it was a much too heterogeneous assemblage, and we may doubt whether the Moine schists, having regard to their history, form a good type. These criticisms, however, affect only points of detail, and some may even regard them as excellences, while as to the general excellence of the table and its high value to students there cannot be the slightest question.

Differential and Integral Calculus for Beginners. By Edwin Edser, A.R.C.S. Pp. vi + 253. (London: Nelson and Sons, 1901.)

THIS is a book written to supply the wants of students in advanced physics who require some knowledge of the calculus to enable them to read treatises on physical science, but who have not time to devote to a thorough study of higher mathematics. It is the outcome of a series of articles printed some time ago in the pages of the *Practical Teacher*. Most of the text-books which have been written on the subject of the calculus treat it too fully, and deal with examples of too complex and difficult a character to be really suited to the needs of students, who chiefly want the calculus to enable them to understand the theory of comparatively simple experimental problems in mechanics and physics. The present little book is one of several that have been written in recent years with the object of supplying this want. The author has treated the subject in a very simple manner, and does not assume the reader to have more mathematical skill than is involved in a familiar knowledge of elementary algebra and geometry. The opening chapter deals with the elements of coordinate geometry, and explains the nature of the circular and exponential functions sufficiently to render it needless for the ordinary student to refer to other books. This is further ensured by the addition of an appendix dealing with trigonometrical ratios and formulæ. Two chapters are spent on the differentiation of simple and complex functions, two others on maxima and minima and expansions, and two more on simple integrations by direct and special methods. This is followed by a section devoted to applications to problems in geometry, mechanics and, more especially, in physics. The final chapters deal with double and triple integration and simple differential equations.

In general the book is well written, and suitable for beginners. A good feature is the introduction of several numerical problems. The subject in this way is more vividly brought to the student's mind than when the examples, as is ordinarily the case, begin and end in

mere symbols. The analytical working out of problems is given with unusual fulness. On the whole this is a distinct advantage to the beginner, though in some cases it has been a little overdone, as, for instance, on pages 190–193, where more than $2\frac{1}{2}$ pages are devoted to the analytical work of a triple integration. Each chapter contains several examples fully worked out, and concludes with a number of exercises to which the answers are appended.

The arrangement of the book is good, but the section dealing with real and imaginary quantities early in the book, and that on the hyperbolic functions towards the end, might have been omitted without much real loss to the beginner, and certainly the former section is introduced too early.

A mistake occurs on page 101 in reference to an application to alternating electrical currents. The arithmetical average has been confused with the square root of mean square, with the result that the statement made is incorrect.

Engineering Chemistry. A manual of Quantitative Chemical Analysis for the use of Students, Chemists and Engineers. Second Edition. By Thomas B. Stillman. Pp. 503. (Easton, Pa.: The Chemical Publishing Co., 1900.)

THIS work is intended to be placed in the hands of the student who is commencing quantitative analysis, and hence the first eleven exercises deal with general elementary determinations, after which he will take up that portion of the book which deals with his special requirements. Schemes are then given for the analysis of coal and coke, iron ores, water, both for sanitary and technical purposes, of coal, oil, producer and flue gases, iron and steel, cement, building materials, paper, soap, lubricating oils, paint and asphalt. On account of the wide scope of the book, the author has secured special articles from experts on blast furnace practice, boiler tests, carbon compounds of iron, practical photometry, electrical units and energy equivalents. As must necessarily be the case from the size of the book and the variety of subjects dealt with, the work is written in a very compressed style throughout, so much so, in fact, that it is scarcely a suitable work to put in the hands of "students commencing quantitative analysis." The large amount of practical information in it, however, will render it a useful work of reference for chemists engaged in engineering work. In some respects there is room for improvement. The superabundance of decimal places in numerical results, which is, unfortunately, characteristic of American technical literature, is very much in evidence. Thus in an analysis of water for technical purposes, the constituents of which, on account of their minuteness, are weighed with an accuracy of about two, or at the most three, significant figures, in the final statement of results no less than five places are given. An even more striking case is in the section on calorimetry, in which the water equivalent of a calorimeter is laboriously worked out to six significant figures, 203·460, the experimental result being casually given as 227·22. Another example is in the determination of the heating value of a gas, the result being expressed as 10726·7 B.T.U. per pound. The section on photometry is somewhat out of date, no mention being made of any standard of light other than the sperm candle. The chapter on pyrometry and many of the numerical data also require bringing up to date, many of the tables and calculations being based upon the weight of a litre of hydrogen taken as 0·08958. A noteworthy feature, and one adding considerably to the value of the book, is the introduction of a short bibliography at the end of each special chapter. It is curious to note that in some cases recent papers of importance are given as references, but ignored in the text. This is especially noticeable in the chapter on pyrometry.

LETTERS TO THE EDITOR.

Darwinism and Statecraft.

EVERY one who is interested in the bearing which the teaching of biology has to the affairs of the nation must have followed with interest not only this last work of Prof. Pearson, but also his many contributions to the subject of heredity. Very opportune, also, is Prof. Lankester's appeal in his review (March 21) to "the greatest in the land," for apart from the fact "that the crowd cannot guide itself in its blind impotence," it is being otherwise led by the hysterical nonsense of a halfpenny Press that is degrading journalism and the people by the substitution of bombastic ignorance and assertiveness for knowledge and real merit.

It seems to me that the statement in Prof. Pearson's book of what the British parent ought to say is just what he should not say, and that the implication in Prof. Perry's review that the development of the faculties ought to begin at the public schools is open to objection because such beginning can and ought to be made very much earlier. The statement which Prof. Pearson would have the parent say would be better if it were altered so that for "son" we should read "children," for surely we require thinking and observing daughters as well as sons; and, moreover, the statement seems to imply that the parent expects the public school or the University to teach his son to think and observe, whereas, if the parent did his duty, the most that he ought to expect of these institutions would be the further development of his children's thinking and observing powers, and not their initiation in these matters.

We need thinking men, it is true; but what is the nature and source of the early influences that makes or mars their careers before they will be brought into contact with the educational system that is to make them thinkers? Are we not on the wrong track when we talk of "making thinkers" or of "training men to think"? Remembering the nature of the child, rather it seems to me that we should be nearer a successful issue if we turned our energies in the direction of retaining and developing the thinking powers it naturally possesses. Any one who chooses to observe the development of a child's mind will, if he does not suppress its natural bent, convince himself that a child from three to five years of age possesses thinking powers of greater capacity than we are in the habit of crediting to it. One of the external evidences of a thoughtful mind is the asking of questions which bear definite and logical relations to each other; and this is precisely what an average child of that age, when talking to a person in sympathy with it, is persistently doing. It is not content with a flimsy and evasive answer, and how strong is its intellectual craving is manifested by its evident disappointment or display of temper when its ignorant parents impatiently curb its curiosity. It is very seldom that one finds a mother who has endeavoured to retain her child's thinking capacities. I was once present when the four-year-old little daughter of such a mother was making inquiries about the planet Venus, and after she had been informed that both Venus and the earth travelled round the sun and were illuminated by it she put the query, "Then if there were people on Venus our earth would look to them like Venus looks to us?" This question demonstrates that a child possesses thinking powers sufficiently vigorous to enable it to see the logical relationships of bodies to each other that would certainly do credit to many of its superiors in point of years. This is not an isolated instance, and my impression, derived from observation and from conversation with observant persons, is that the average child, if not suppressed, is capable of a quality of thinking that leads its elders, when they try to follow it, into an intellectual quagmire of inconsistency and absurdity from which they beat an inglorious retreat by angrily bidding it "not to ask silly questions." If they bid themselves not to give silly answers their request would be just. Let me give an instance of the intellectual stagnation upon which the children who will become the nation's men are being reared. I once heard a child ask its mother, "What makes the flowers grow?" Promptly came the answer, "Jesus!" No wonder when children's intellects are muddled with such unprovable assertions that they cease to think. I recall my

own younger days, and the questions I wanted answered: they were answered negatively as a rule, and those that were positively so never allowed me to reconcile them with the facts around me, and I have since learned that they were mostly perversions of the truth, designed to secure a theological end. Little wonder I ceased to think by the time I got to school, and it is a matter of surprise to me that the examination system which followed did not convert a state of abeyance into one of absolute destruction.

There is no need to "make" thinking men; they are born to us if we will but retain, develop and strengthen the qualities that every healthy average child possesses. But to do this we want, above all else, thoughtful, intelligent and well-informed women who, as mothers, will recognise their duties to the State and will endeavour to retain and train the natural qualities, physical and intellectual alike, of the children that are to become the nation's men and women. The old style of domestic wife and mother—an uninteresting, mechanical drudge or a gaudy doll—may have been good enough for our forefathers, but for us it means loss of national time and energy which, if utilised, can be converted into factors capable of retaining the supreme position that we are fast losing. Granting that the results of a mother's pernicious training can be remedied in later life, it is obviously waste of valuable energy, time and money to organise an elaborate system of education to undo that which ought never to have been done. And, therefore, I urge that our national progress depends very largely upon "the hand that rocks the cradle": if it rocks that with an intelligent purpose, it will be well with our future men; if not, then England, like Tyre, Venice and Rome, "whose greatnesses it has inherited," "must be led, through prouder eminence, to less pitied destruction."

G. P. MUDGE.

THE ROYAL LIBRARY AT NINEVEH.[1]

OUR readers who are in the position of being able to recall the "discovery" of Nineveh, which was announced between the years 1845 and 1854, will have no difficulty in remembering that the exhuming of colossal bulls and bas-reliefs from the site of the palace of the great kings of Nineveh was almost contemporaneous with the discovery of the means whereby the wedge-shaped characters, which were found cut upon them in long, symmetrical lines, could be read and understood. It was a coincidence of the most remarkable kind that the excavations at Nineveh yielded at that time such a large mass of new material for Rawlinson, Norris and Hincks to work upon, and it may be safely said that the correct information concerning Bible history which they succeeded in producing from it convinced the general public of the trustworthiness of Rawlinson's system of decipherment more effectually than his epoch-making translation of the inscription of Darius the Great, which was cut on the face of the now famous rock of Behistun, would ever have done. The bulls and colossal figures and bas-reliefs, which Sir Henry Layard drew out of their hiding places, appealed strongly to the popular imagination, which already at that time saw in them the prototypes of the mysterious figures that the prophets of the Hebrew god Yahwe saw in their visions, but for the scientific seeker after the knowledge of the long-lost cuneiform language they did little. It was soon recognised that the texts engraved upon them contained many duplicates, and also that they did little more than set forth, in stereotyped and vaunting phrases, the names and titles which the kings of the Second Assyrian Empire arrogated to themselves. But further examination of the smaller objects which were found in the ruins of the Assyrian palace at Nineveh resulted in the discovery of a large collection of "tiles," as they were first called, made of baked clay, which were inscribed with texts written in cuneiform with minute characters, and this "find" is, for cuneiform decipherment, probably the greatest which has ever been made. An investigation of these minutely written texts showed that they consisted of lists of cuneiform signs arranged on a definite plan, of lists of words and phrases, and of connected narratives, which might well come under the general description of "literature"; in fact, the thousands of tablets and fragments of tablets which had been sent home, without the least idea of their value having entered into the heads of those who found them, turned out to be neither more nor less than the fundamental matter upon which the whole of the great superstructure of Assyriology has been built. We now know of a certainty that, at the close of the eighth century before Christ, Sargon, king of Assyria, possessed a few tablets, the contents of which concerned the business of his kingdom, and that he kept these in a chamber in his palace. It seems also that his two successors, Sennacherib (B.C. 705–B.C. 681) and Esarhaddon (B.C. 681–B.C. 668), added other tablets to Sargon's, and that we may also regard the united collections of these great kings as the nucleus of the Royal Library at Nineveh.

The great literary king of Assyria was, however, Ashurbanipal, and it is to him that the world is indebted for whatever knowledge of the Assyrian and Sumerian language it possesses. This mighty hunter and warrior found time to take an interest in the welfare of the literature of his country, and he spared neither pains nor expense in the formation of his library and in making it to contain a truly representative collection of tablets. His interest was twofold, for he was anxious to preserve both the best works written in his own native Semitic language and those which had come down in a more or less fragmentary condition from the Sumerians, a mighty people who seem to have given to the Semitic inhabitants of Mesopotamia nearly all that they ever possessed in the way of literature. With this object in view he had copies of many of the great Sumerian literary compositions made, and to these he attached translations in Assyrian, arranged interlinearly, a fact which seems to indicate that the knowledge of Sumerian was disappearing from among his people when he began to reign. Literary compositions were, however, not the sole objects of his care, for he collected the materials necessary for learning and teaching both the Assyrian and Sumerian languages, and evidences of this are the important remains of the syllabaries, sign-lists, vocabularies, &c., compiled by his orders, which are now among the most precious possessions of our National Museum. Wherever rumour declared that a valuable document existed he sent scribes and messengers to take a copy, or copies, of it, and the accuracy of such copies is attested by the fact that defective or illegible words or passages in the archetype were generally indicated as such in the copy or copies made for Ashurbanipal.

The above preliminary remarks are sufficient to indicate the value of the thousands of baked clay tablets and fragments which were found at Nineveh; but it has for many years past been a problem of some magnitude to Assyriologists how best to make use of the mass of material which exists. It is manifestly impossible for every student of cuneiform to possess the time and means necessary for examining and copying texts from thousands of tablets, and besides, few students are sufficiently skilled in reading cuneiform from tablets to make it worth their while to devote months to the work.

The late Sir Henry Rawlinson made a noble attempt to lay before Assyriologists the best of the texts in his monumental publication entitled "The Cuneiform Inscriptions of Western Asia," but this work, after all, only contains a *selection* of the texts available, and at the time of publication no scholar possessed the knowledge necessary for arranging and classifying the various documents which existed among the remains of the works of the Royal Library at Nineveh. It must not be imagined

[1] "Catalogue of the Cuneiform Tablets in the Konyunjik Collection of the British Museum." By C. Bezold. 5 vols. Printed by order of the Trustees. (London, 1889–1900.)

that work of classification can ever become simple, for the greatest difficulty will be experienced for years to come in joining up the various fragments which go to form a complete tablet. At the sacking of Nineveh by the Medes, many of the tablets which were made and collected with such care by Ashurbanipal appear to have been wilfully broken, and fragments of them were scattered in all directions; some were destroyed by fire and others crushed into dust.

A visit to the Nineveh Gallery in the British Museum will explain the difficulty to the reader in a few minutes, for in the cases there will be seen exhibited several tablets, or large portions of tablets, which are composed entirely of little pieces which have been joined together by the skill of generations of students of Assyriology. There are examples in which three or four of the fragments which help to form a tablet have been brought home from Nineveh by three or four different "discoverers," and many tablets must remain imperfect until the pieces necessary to complete them have been brought home from the ruins of the great palace at Nineveh, *where they still lie* awaiting the spade of the excavator.

The work of publishing the texts from the Nineveh Library which was begun by Sir Henry Rawlinson was carried on by Norris and Smith, and at a later period a number of foreign scholars began to publish works which professed to give amended and correct versions of some of their copies; but all were unsatisfactory in a greater or lesser degree, because the groups of texts which were reproduced were incomplete. Every student felt that he had not got all the existing materials for his work before him, and that any result which he arrived at one day might be upset the next by the identification of a fragment hitherto unnoticed in the British Museum collections.

Matters went on in this fashion for some years, but at length the late Sir Henry Rawlinson took the matter up and brought before his fellow Trustees of the British Museum the bold suggestion that a complete catalogue of the Nineveh, or Konyunjik, Collection should be prepared under their direction and issued by them as a British Museum publication. There is no need to point out here the leading part which the Trustees of the British Museum have always taken in promoting the interests of Assyriology; but it may be said in passing that, but for their powerful aid in advocating the importance of the subject, and the publications of texts which they have issued, practically regardless of cost, that science could never have attained to the position it now occupies, and its progress would have been retarded for a generation. In accordance with their enlightened policy, the Trustees decided to print the proposed catalogue of tablets, and the bulky work which we now have before us is the result.

The "Catalogue of the Cuneiform Tablets in the Konyunjik Collection of the British Museum" was prepared by Dr. C. Bezold, who is now professor of Assyriology in the University of Heidelberg, and is the author of some other works on his special subject. The Catalogue fills five volumes, which were published in 1889, 1891, 1893, 1896 and 1899 respectively, and contains 1949 pages, large royal 8vo, of descriptions of tablets; 265 pages of "General Index"; 154 pages of "Index of Reference Numbers"; a Bibliography of 13 pages; a brief Introduction of some 18 pages, besides the lists of texts published in Rawlinson's great work, "The Cuneiform Inscriptions of Western Asia," and several pages of preliminary matter issued with each of the first four volumes. The plan adopted by Dr. Bezold is, first, to give the size of each tablet or fragment, and to state, if a fragment, its position in the tablet of which it once formed part, *i.e.* he tells the reader if the fragment belongs to the top, middle, or bottom part of the tablet. These remarks are followed by details concerning the style of writing, its state of preservation, and notes which will serve to identify it. Next we are usually told what the contents of the tablet are, but if this is not possible the general character of the inscription is clearly indicated; extracts from colophons, "catch-lines," &c., are often given in the original cuneiform, as well as many passages of importance from a linguistic or historical point of view. Last, but not by any means least in importance, Dr. Bezold tells us under the description of each document where the text has been published, or quoted, or referred to, or translated, so that up to the time of the publication of each volume the Catalogue was not only a guide to the tablets, but also to the published literature which related to it. At the end of each description we find given the number by which it is known in the registers of the British Museum.

An objection which will be made to the usefulness of the work is, that the tablets described are not arranged in classes, but this may fairly be met by referring the objector to the very full General Index, which we have already mentioned, and its headings and subheadings. Thus, under the heading "Letters" we have twenty-seven closely printed columns of numbers, in which the reader is told the number of nearly every letter and report catalogued in the work and the page where the description of each will be found; the subheadings state which letter refers to public and which to private affairs, and the groups are usually very well and clearly defined. With many subjects, however, the classification might have been carried much further, and the subheadings might have been multiplied with great benefit to every student of the Catalogue; on the other hand, the page numbers have nearly doubled the size of the Index, and might with advantage to him have been omitted so far as K numbers are concerned.

We think the decision to print the descriptions under the register numbers was a wise one, for beyond all doubt it has tended to advance the progress of Assyriology, and has materially aided students of Assyrian in both hemispheres; had it been decided to classify the tablets and fragments before printing, it is doubtful if Dr. Bezold's work would ever have seen the light.

The boundaries between astrology and astronomy, and magic and religion, and legend and history were so loosely defined by the Assyrian *savants* that the student of to-day is often sorely puzzled as to the class in which he should group certain documents, and experience shows that his doubts on the subject may be as far off from satisfaction five years hence as they are to-day.

In addition to the general contents of the volume described above, mention must be made of the twelve excellent plates, in which a number of cuneiform tablets and fragments, selected chiefly for their forms and philological importance, have been reproduced by a photographic process. With the help of these and the remarks which Dr. Bezold makes in his Introduction, the intelligent reader will have no difficulty in gaining a good general idea of the principal classes of tablets which are to be found in the Nineveh Collection, and of their appearance, and with care he may even make some progress in the difficult subject of palæography. It will surprise no one to learn that the student who has specialised in any one small branch of Assyriology will be able to pick holes in some parts of Dr. Bezold's work; but in a progressive science like Assyriology this can never be avoided, especially as the publication of the Catalogue extended over a period of ten or eleven years. In fact, Dr. Bezold has himself supplied, in the later volumes of his Catalogue, the information which has enabled others to modify some of his statements and descriptions in the early parts of his monumental publication.

The space at our disposal will not admit of any even approximately detailed account of the contents of Ashurbanipal's great Library, but a general indication of the

chief classes of literature preserved in it must be added here.

Of almost the first importance for us are the large official authentic annals which were drawn up under the personal supervision of the high officials of the king, from which we gain very full accounts of the military expeditions undertaken by Sargon II., Sennacherib, Esarhaddon, and Ashurbanipal, and of their building operations. Intimately connected with these were the letters, despatches and reports written chiefly by the king's officials in various parts of the country, who by this means kept him informed of the progress of events in the countries under their jurisdiction. This class of document is of peculiar interest, and being in many cases dated they often afford precise information about important matters.

Next in importance come the tablets which deal with chronography and chronology, and by means of the so-called "Eponym Canon" it is possible to fix with exactness the dates of events which took place from about B.C. 900 to B.C. 640.

The business side of Assyrian life is represented by a considerable number of "contracts," which relate to all the principal matters concerning the transfer for payment of human beings, and of property of all kinds.

A very large class of tablets deals with astrology, and provides innumerable examples of omens of all kinds; these prove that the warlike Assyrian must have lived in a state of almost abject fear of the various spirits and demons with whom he peopled heaven and earth. Every event which happened was construed as a portent, and the Assyrian astrologer must have spent most of his time in tabulating forecasts. Diseases were cured by means of incantations and magical formulæ, for all diseases, both of mind and body, were believed to arise through the evil influences of the stars; such influences could be diverted, however, by the use of certain herbs, plants, stones, and portions of the bodies of animals. The ghost, the "evil foot" at the door, the evil dream, the bite of a snake, the sting of a scorpion, were all treated in much the same way, *i.e.* by magical means. Two great series of incantations have been identified, and the rubrics of some of the texts reveal a depth of superstition in the mind of the Assyrian which seems almost incredible. The burning of magical figures made of clay, bitumen, honey, flour, bronze, or wood during the recital of magical formulæ was, of course, common, and it is quite clear, from the documents of this class, that the Assyrians thoroughly earned their name of "magicians and sorcerers." Curiously enough, the Library included large numbers of prayers, many of which contain expressions of lofty spiritual ideas, but these show at the same time that the Assyrian religion never freed itself from the shackles of the basest superstition. Many religious texts describe and contain instructions for the performance of important rites and ceremonies, and most minute instructions concerning the offering up of sacrifices, the festivals of the gods, the dress of the priests, &c.

The legendary lore of the Assyrians is of peculiar interest, for it has preserved the history of the Creation and the account of the Deluge, which were incorporated by the Jewish compilers of the Hebrew Bible in Babylon.

We have already spoken at some length of the syllabaries, sign-lists and vocabularies which Ashurbanipal had drawn up, with Sumerian renderings arranged interlinearly, and from a modern point of view these will probably be regarded as the most valuable section of his Library. Dr. Bezold's Catalogue represents a vast deal of time and patience and hard work, and he is to be congratulated on the completion of a long and laborious task. There is no doubt that it will stimulate many in the prosecution of their Assyrian studies, and that it will greatly facilitate the rejoining of fragments of tablets; it will also help an investigator of any given class of tablets to produce an edition of its texts, which may be regarded as final until the tablets which still lie buried under the palace ruins at Nineveh are brought home to Bloomsbury. The thanks of every student of Assyrian are due to the Trustees of the British Museum for the production of such a costly but useful Catalogue.

NAVAL BOILERS.

THE interim report of the Admiralty Committee upon "Modern Types of Boilers for Naval Purposes," recently published, has caused much discussion; but, up to the present, it appears to have satisfied nobody and not to help the Admiralty much to settle the grave question of the best boilers for the future in the Navy. It gives the views, which are not so mature as could be desired, of the mercantile marine engineers of which the committee was chiefly composed, the experience of whom, up to the date of the appointment of the committee, had evidently been limited to the discarded cylindrical boiler.

The committee were asked (1) whether they consider water-tube boilers more suitable than cylindrical boilers for naval purposes; (2) if so, whether the Belleville is the best type of water-tube boiler for H.M. Navy; and (3) for suggestions on the extent to which any particular type or types of boilers should be fitted in new vessels. The replies given in the report are that "a satisfactory type of water-tube boiler" would be more suitable than the cylindrical boiler; that the Belleville boiler is not the type of water-tube boiler best adapted to the requirements of H.M. Navy; that Belleville boilers be not fitted in any ships not yet ordered, nor in any ships recently ordered for which the work upon the boilers is not too far advanced; but that they be retained in all completed ships and in all ships under construction for which the work is so far advanced as to involve delay in completion if the boilers were to be altered. The committee state that they have had under consideration four types of large straight tube boilers which have been tried in war vessels, viz., the Babcock and Wilcox, the Niclausse, the Dürr, and the Yarrow large tube boiler; and they suggest that "if a type of water-tube boiler has to be decided on at once for use in the Navy," some or all of these be taken. They recommend that boilers of these types be made and experimented with at the earliest possible date; and they call attention to the practical objections that have been found to the construction and working of the Belleville boiler.

The committee make the important admission that when the Belleville boiler was introduced into the Navy they consider "there was justification for then regarding it as the most suitable type of water-tube boiler for the Navy."

The only naval engineer upon the committee concurred with the report except that he considered, although the Belleville boiler has certain undesirable features, "it is a good steam generator, which will give satisfactory results when it is kept in good order and worked with the required care and skill"; and he sees "no necessity for delaying the progress of ships which have been designed for Belleville boilers in order to substitute another type of boiler."

This report does not satisfy the parliamentary opponents of the Belleville boiler, who appear to object to water-tube boilers of all kinds, and to advocate a return to the cylindrical boiler. In spite of the great advance recently made in the designs of boilers of water-tube type, they argue that because early attempts to use water-tube boilers at sea were unsuccessful, it is hopeless to expect any good results from those now available. These opinions are not endorsed by engineers of wider experience, especially by the designers of machinery for warships, who understand better the relative advantages and disadvantages

of different types of boilers from the point of view of warship requirements.

The Admiralty do not get much guidance from the report, and we understand that they only intend to supersede the Belleville boilers by those of Babcock and Wilcox and of the Yarrow types in a few vessels recently ordered, for which the boilers have not yet been put in hand. They had previously arranged for one of the recent cruisers to be fitted with boilers of the Niclausse type. The experiments recommended by the committee will doubtless be carried out as quickly as possible, after which there may be sufficient data available for determining the policy of the future.

The committee's report is distinctly disappointing, and suggests that their experience and judgment were not sufficiently matured to give much value to an interim statement. They seem to have been impressed by the advantages of good water-tube boilers for naval purposes, and to have realised that an ideal water-tube boiler—which, however, has not yet been approached in practice—would be much better for the Navy than the old cylindrical boiler. When they have to choose the best of the types that are available, they name four which they have had under consideration and recommend early experiments with them, and there they leave the matter. Meanwhile, the construction of battleships and their machinery must go on, and the Admiralty engineers are in the difficult position of having to decide upon the boilers for them. This task is not rendered easier for the Admiralty in carrying on the work of the Navy, nor is any one helped in forming an opinion upon the best policy for the future by the fact that the objections to the Belleville boiler which are pointed out by the committee apply, in a greater or less degree, to others that might be substituted for it. One thing that appears certain is that whatever the defects of water-tube boilers may be, or may be thought to be, their advantages to a warship are sufficiently proved to make a return to cylindrical boilers in the fighting navies of the world extremely improbable.

FORESTRY IN GREAT BRITAIN.

It is probably known to most people that for the supply of our requirements in the matter of timber, as in that of foodstuffs, we depend largely upon imports from abroad. But it may be doubted if many beyond the comparatively few who have given special attention to the subject have realised the fact that the annual cost to the country of these imports amounts to somewhere about twenty-five millions of pounds. It has been often urged that it would be worth some trouble to prevent this large sum, or a portion of it, going out of the country, and it has been pointed out that a proper system of forest management would bring about this result. Of course, so long as the foreign supply is ample and the price of imported timber is less than that at which it is profitably produced at home, our markets will continue to absorb foreign produce as heretofore; but these conditions which have hitherto prevailed are, in the opinion of experts, not likely to continue. For some years past this and cognate questions have attracted considerable attention, as witness the writings of recent date noted below,[1] all of which are deserving of careful perusal. The burden of all of them may be summed up in the phrase cited by a writer in the *Times* of March 17, 1899. "'Cotton,' it is said on the other side of the Atlantic, 'was once called king; but King Cotton is a lesser potentate than King Timber must soon become.'" In other words, the world's demand for timber is outrunning the supply under present methods, and an appreciation of timber values is therefore setting in which is likely to be permanent and progressive. Cheap timber is probably a thing of the past in this country. To some such a declaration will only appeal as the old cry of "wolf," and they may argue that any scarcity of timber will be balanced by the substitution for it, in many cases, of other suitable products; and such substitution has, no doubt, in the past taken place, as, for example, in shipbuilding. But it must be remembered that facility of transport has by now led to inroads into the world's timber capital in practically every timber-producing region, and the ruthless destruction of virgin forest without attempt at regeneration has brought us now within measurable distance of the end of the natural supply; and, further, in recent years the applications of timber to other purposes than those of construction, as, for example, in the manufacture of wood-pulp, have made it an efficient substitute for other products, and thus the demands for it have been multiplied, and may be yet increased. In these circumstances, then, not from any sentimental ideas connected with the growing of timber at home, but from the standpoint of business principles, the question of the growing of timber in Great Britain to an extent which shall in some measure make us less dependent upon foreign supply is one which has now assumed practical importance.

That wood can be profitably grown in Great Britain, even under the unscientific methods now in operation, has been amply proved; that under a system of scientific management crops of timber could be raised to yield a certain and adequate return upon capital is demonstrable. What lies at the bottom of the absence of such crops in this country is want of appreciation, from land-owners down to the working forester, of the right principles upon which they can be grown. There is, speaking generally, no practice of scientific forestry in Great Britain. Other immediate causes there are which have contributed more or less to the neglect of scientific forestry in Britain, for instance, tenure of land, the claims of sport—this probably one of the most influential factors—the rating of woods, and so forth. These are obstacles, and no doubt will remain so, in the way of tree-planting; but assuredly were our landed proprietors, land-agents and foresters better instructed in the methods of growing timber and in the possibilities of remunerative crops, less would be heard of them as such. It is difficult to instil into those who have been brought up in other traditions the fact that trees which are to yield a crop of timber must be grown under rules as definite as those which govern the cultivation of ordinary agricultural crops, because the time which is required for the maturation of the crop and the securing of the final yield exceeds the lifetime of the individual. Yet it can only be when this fundamental fact has been realised that a supply of marketable home-grown timber will be available in Great Britain.

There are not, it is gratifying to note, wanting indications that already some proprietors, even the Government, are appreciating the necessity and the advantage of cultivating their woods upon rational lines. Working plans for the economical management of woods have been prepared and adopted upon estates of the Earl of Selborne in Hampshire—of which an account will be found in the *Transactions* of the Royal Scottish Arboricultural Society already cited—of the Duke of Bedford at Woburn, of Mr. Munro Ferguson at Raith and Novar, and in the Forest of Dean the Government has similarly arranged a working plan. These working plans, which are a novelty in the country, are worthy of study by those who own woodlands, for they indicate the method which ought to be followed upon every estate where it is desired to grow wood for profit. Hitherto proprietors who

[1] "Forest Management, with Suggestions for the Economic Treatment of Woodlands in the British Isles" (*Trans.* Surveyors Inst., 1900); "Canadian Trade with Great Britain" (*Contemp. Review*, Jan. 1900); "British Forestry and its Prospects" (*Trans.* Roy. Scot. Arbor. Soc., vol. xvi. part II, 1900); "Deficient Production of Timber in the World" (*Trans.* Eng. Arbor. Soc., vol. iv. part III, 1900); "Outlook for the World's Timber Supply." Report of a lecture by Dr. W. Schlich (*Journal of the Society of Arts*, March 1).

may have desired to cultivate their woods on scientific principles may have met with the difficulty of obtaining expert advice; but such a difficulty no longer exists, for there are in this country now retired forest-officers of the Indian service to whom proprietors may readily go for sound and safe guidance. At the same time we cannot hope that the cultivation of crops of timber in this country will attain the dimensions which it must do if it is to affect to an appreciable extent the market supply of timber until means for the acquisition of knowledge of scientific principles underlying it are available to those to whom woods belong and to those who have the direct management of the woods. Within the last decade several trustworthy text-books upon forestry have appeared, but our only school for instruction in forestry at the present time is that at Coopers Hill. Coopers Hill is, however, open only to entrants to the Indian Forest Service, and there is no institution in the country to which any one desiring a thorough acquaintance with the principles of forestry can go. Our Universities are now alive to the claims of agriculture as a subject of study, and agricultural colleges are being formed in different districts. How long will it be before the Universities recognise that forestry also is worthy of attention, or the agricultural colleges take up the subject in their curricula? It is matter of common knowledge that a committee appointed by the Secretary of State for India recently reported in favour of the transference to Cambridge of the forest-school from Coopers Hill. As yet, however, no action has been taken upon the recommendation. The Secretary of State may rest assured that such a transference would be a reform meeting with the hearty approval of men of science, and the presence at Cambridge of such a school would give an opportunity to undergraduates connected with the landed interest to obtain some acquaintance with a subject of intimate concern to them. The influence of this upon the prosperity of the country would ultimately be most beneficial. As has been said above, ignorance is the real cause of our present condition as a wood-growing country, and until systematic instruction is provided in some of our Universities or colleges there will be no great reformation in forestry practice, although there may be amelioration through the action of intelligent and far-seeing individual proprietors.

THE CONCRETIONS OF THE CONNECTICUT VALLEY.[1]

THE curiously-shaped concretions met with in the Champlain clays of the Connecticut Valley have for many years attracted attention. Indeed, so long ago as 1670 some specimens were sent to the Royal Society of London. A detailed description of them and of their mode of occurrence, illustrated by fourteen beautiful quarto plates, has now been issued by Mr. J. M. Arms Sheldon. Four principal types of concretions are met with; some are discs which call to mind the Kimeridge coal-money; some are cylindrical or club-like, one example (probably a compound one) being a little more than twenty-two inches long; others are botryoidal, and not a few are "queer little images" resembling "fishes, birds, ant-eaters, elephants, dogs, babies' feet," &c. (Fig. 1).

These occur in stratified river-drift clays, some of which are of a kind suitable for modelling, and some are more or less gritty. The most remarkable point is that "each clay bed has a form of concretion peculiar to itself," that is to say, the principal types are never found together. The author has seen "forty-eight specimens from one bed so similar it was impossible to tell one from another."

[1] "Concretions from the Champlain Clays of the Connecticut Valley." 4to. (Boston, 1900)

Compound forms occur, where, for instance, two or even three discs have coalesced or been joined together (Fig. 2); and intermediate stages of such examples, and of immature concretions of horse-shoe type, are met with.

These remarkable bodies occur along the planes of bedding in the clays, and the lines of stratification may sometimes be seen to run in unbroken continuity through concretion and clay. In composition they consist of argillaceous and somewhat sandy limestone with small amounts of iron-oxide, magnesia and manganese oxide. They contain from 42 to 56 per cent. of carbonate of lime, whereas the clay possesses but 2 or 3 per cent. The concretions spread out laterally in the clay, as if water holding carbonate of lime in solution made its way

FIG. 1.—An animal form of concretion.

along the planes of stratification; and unless in the case of tiny spheroidal concretions they are almost invariably flattened. No doubt they are due to the obscure process of segregation, whereby the mineral matter, tending to collect together, has been unable to assume definite crystallographic shape, but has concentrated itself in nodular form. Some of the concretions show evidence of concentric structure, but no appreciable nucleus has, as a rule, been seen, though it might have consisted of a particle of carbonate of lime. Evidently the concretionary process went on in a quiet way, but not always uninterruptedly, as indicated by the distinct stages of growth seen in some specimens. The shape of the concretions is held to be partly determined by the structure

FIG. 2.—A treble form of symmetrical concretion.

and composition of the matrix which holds it, and by the amount of carbon dioxide and other organic acids present.

The author concludes his work with a useful bibliography, wherein the well-known researches of De la Beche, and the observations of A. H. Green and others are mentioned; but we miss the name of Sedgwick, who, in 1835, brought the matter before the Geological Society of London. The author, however, does not enter into the general question of concretionary structures; his work is essentially local, but it will be none the less interesting to those who give attention to the subject.

H. B. W.

THE WILDFOWL OF SCOTLAND.[1]

THE possession of artistic talents of the exceptionally high order of those with which the author of the beautiful volume before us is endowed confers, it must be confessed, an advantage over his brother naturalists to whom such accomplishments are denied the value and importance of which it is almost impossible to over-estimate. Most naturalists who have to depend upon the labours of others to illustrate their works (and they are the great majority of their class) have but too often to deplore either the lifeless and "wooden" character of the sketches with which they are supplied, or, when higher things are attempted, the sacrifice of accuracy of detail to artistic effect. For, among at least a large percentage of professional zoological artists, the combination of lifelike posture with strict attention to details of form, colour and anatomy seems to be almost unattainable. An artist like Mr. Millais, on the other hand, who is well acquainted with the special characteristics of the animals he portrays, and is at the same time an accomplished landscape and animal painter, is enabled to combine zoological accuracy of detail with scenic effect in the happiest manner. And we have in consequence pictures of animal life which satisfy the professed naturalist in regard to fidelity, and likewise appeal with full strength to the connoisseur in art and the lover of the beautiful in nature.

In an earlier work, "A Breath from the Veldt," Mr. Millais gave us some startling, but apparently truthful, sketches of antelopes and vultures in their most active phases of movement; and in the present volume he has done the same for the British ducks and geese and certain other of our larger wild birds. Examples of the artist's power and originality in this style are displayed in the plate of a peregrine swooping down on a flight of frightened teal; in the one of wild geese arriving from the Arctic regions, where the figure in the foreground is a marvellous example of artistic skill in representing a bird in what seems an almost impossible attitude; and, again, in the plate of herons moving a party of wigeon; and also in the sketch of Loch Spynie at sunset, in which the whole scene is alive with bird-life. Equally bold and original are the sketches of flocks of wildfowl when raked by a shot in their midst; but we confess that such scenes of slaughter are much less to our taste than those of birds under more normal conditions, and we should have liked the coloured plate of a flying mallard far better had the bird been unwounded. Nor is the artist in any way less at home in his pictures of bird-life in repose or slow movement, of which the plates of mallards feeding, of wild geese throwing out sentinels, and of teal in "bunched and scattered formation" may be cited as charming and exquisite examples. As an example of illustration of this nature we reproduce, by permission of the publishers, the annexed text-figure of mallard feeding. The flight, too, of ducks and geese, as we shall have occasion to mention again, is a favourite subject with Mr. Millais; and as an example of the V-formation nothing can be better than the plate, entitled "brent and their satellites."

FIG. 1.—Mallard feeding in the shallows and on the mud. From "The Wildfowler in Scotland."

To those who have had no experience of wildfowl shooting in Scotland and the isles, nothing can be more wonderful than the profusion in which ducks and geese occur during winter in their favourite resorts; and few sights in the world can be more marvellous than the flocks of these birds when assembled in their thousands and tens of thousands. Most wonderful of all, perhaps, must be the arrival of wild geese from the Arctic regions. By rare good fortune, as he tells us, the author has on two occasions witnessed this marvellous sight. On the first occasion, in October, he writes:

"I heard the first 'honk' of the season coming from far away up in the vast expanse of the blue heaven. For a long time nothing could I see, until at last a tiny speck appeared in the sky as far as the eye could reach, and, watching it intently, I saw it grow into the form of a goose that was slowly descending in great spirals. This bird was followed at regular intervals by others of the tribe subdivided into little parties of from six to ten individuals. . . . The prime leader came down immediately above the Inch, and while she was preparing to alight there were still small companies evolving themselves from the blue expanse, until at last there must have been some fifteen hundred birds actually on the wing, all in process of descent, and all following one another at regular intervals. By and by, when the leading geese had settled, the parties at the rear seemed to straggle more, and longer intervals occurred between them; yet they kept coming in all day as I roamed round and about the lake, till by the evening, when I disturbed the company, there must have been between two and three thousand geese sitting on the island."

A keen and enthusiastic sportsman himself, Mr. Millais writes mainly for his brother sportsmen, and much of his work, apart from the illustrations, will be interesting to them and to them alone. And this being so, he has done well in alluding to the birds whose haunts and habits he describes so graphically by their English names alone. But the author may also lay claim to be regarded as a field-naturalist of no mean ability, and many of his observations with regard to the flight of ducks are not to be found in any of the ornithological works with which we are acquainted. Several of the more interesting of these observations are given in the appendix, which is specially devoted to the appearance on the water of the different British ducks and the localities they especially affect in Scotland, and is accordingly

[1] "The Wildfowler in Scotland." By J. G. Millais. Pp. xv + 167. Illustrated. (London: Longmans and Co., 1901.) Price 30s. net.

the section of most importance to the naturalist. The following passage, from p. 37, may be quoted as a good example of the closeness of the author's observations:—

"Most sportsmen," he writes, "will have noticed that duck when travelling prefer flying over water; even when passing from one sheet of water to another they will avoid the land if they can. This may be said to be a hard and fast rule with all the true diving ducks, but not with the surface feeders, such as mallard, wigeon and teal; for when they in their flight observe the waters for which they are heading, they are as likely as not to cut over large extents of land to reach their desired haven, especially if they have been much shot at at any given point on their usual water route."

The text-figures in the appendix are especially intended to illustrate the modes in which different species of duck rise from the water, and the formation they assume when in the air. One exhibits the manner in which mallard and teal "scoot" along the surface of the water in close phalanx before rising; a second (herewith reproduced) displays the "bunched" formation assumed by eiders when rising; while a third shows the swallow-like flight and linear formation so characteristic of the long-tailed duck.

FIG. 2.—Eiders rising and showing bunched formation. From "The Wildfowler in Scotland."

For many of the species referred to the author well says that the illustrations best display the manner in which they severally leave the water when alarmed. When illustrations are lacking, excellent descriptions are given, as witness the following:—

"Shovellers are easily recognised when they rise from a marsh by the rattling noise they make, and I have heard them designated as 'rattle-wings' in more than one locality. They ascend abruptly at first, and fly rather like wigeon, but more easily and gracefully. They are adepts at turning, and seem to enjoy in spring beating up and down for hours together over the marsh which they intend to make their summer home. They do not fly very high as a general rule."

With this quotation we take leave, regretfully, of what is in every respect a very charming book, acceptable alike to the lover of art, the sportsman and the naturalist, and forming a handsome addition to the works allowed a permanent place on the drawing-room or library table.

COOPERS HILL COLLEGE.

THE report on this institution by the body called, on the *lucus a non lucendo* principle, the "Board of Visitors," was published last week so shortly before the House of Commons adjourned for the Easter recess that there was not time to take any parliamentary action.

The day after we went to press a letter appeared in the *Times* from Colonel Pennycuick, the president of the College who preceded Colonel Ottley, from which we make the following extracts:—

Sir,—The final decision of the Secretary of State for India, after the inquiry promised in his letter to Sir William Anson, has now been announced, and has justified the opinion expressed by every one acquainted with the facts, that the inquiry in question would be a farce, the Board of Visitors, by whom the inquiry was conducted, being already committed to an opinion, and its own competence being one of the very questions on which an inquiry was most urgently required.

Lord George Hamilton's letter to Sir William Anson repeats the libels contained in his reply to the deputation which waited on him earlier in the year, that the college "is in such a condition that it must be either reformed or abolished," and that it is "a burden upon the Indian revenues." Both these statements, unless they have been justified by something that has happened since the end of 1899, are absolutely untrue. At that date the number of candidates for entrance far exceeded the number for whom accommodation was available; the standard of the entrance examination had been steadily raised during the three previous years, and was still further raised in 1900; the college accounts during the same years showed a handsome surplus of income over expenditure; and the reputation of its students for practical efficiency stood at the highest possible level; its associate's diploma was accepted by the Institution of Civil Engineers as equivalent to their own associate's examination, and this latter examination was passed, while still at the college, by many students who did not succeed in obtaining that diploma; every student who obtained the ordinary diploma of the college, and some who did not, obtained useful employment within a few months after leaving the college. When and whence arose the necessity for "reform or abolition" in an institution which eighteen months ago was producing such results as these?

In his reply to the deputation Lord George Hamilton stated that shortly after he came into office—*i.e.* in the end of 1895 or early in 1896—he "determined to reorganise" the college as an alternative to abolition. If he did, I can only say that he

kept this determination a most profound secret from the college authorities.

I had three personal interviews with him during 1896 and 1897, and neither then nor at any other time while I was president of the college did he give the smallest hint that any dissatisfaction was felt with its condition (except on financial grounds) or that anything in the shape of reorganisation was contemplated or desired; I challenge production of any official document pointing to the necessity for any reorganisation, or for any change beyond those slight alterations which are from time to time necessary in every living organism. A Minister would deserve impeachment who really held the views which Lord George Hamilton professes to have held in 1896, and took no steps to give effect to those views, but continued to speak, publicly and privately, in the highest praise of an institution with which he was in reality so profoundly dissatisfied.

The committee of 1895, to which Lord George Hamilton refers, and whose proceedings occupy so large a space in the Blue-book, did not deal at all with the question of efficiency nor with the teaching staff, but with the financial question alone, a question which at that time appeared somewhat pressing, but which has lost its interest in view of the increasing prosperity of the college during the years succeeding 1895; this latter fact is concealed in the Blue-book by the ingeniously simple process of giving the accounts only down to 1895 and suppressing those of the later years.

. . . . . .

The India Office have striven to represent the question at issue to be whether the personal interests of the professors concerned are to outweigh the interests of the public service. The real question is not this, but whether these latter interests require or justify the drastic changes which have been made.

With an experience of the Indian Public Works Department and of Coopers Hill considerably greater than that of the present president, I assert most positively that they do not, and am prepared to prove this assertion to the satisfaction of any unprejudiced authority. I believe that I could prove it to the satisfaction of the Secretary of State himself, if I could get at him without the intervention of a prejudiced board or of hostile officials.

It is hoped that some means will yet be found to prevent irreparable injury from being inflicted on an institution which has such a splendid history and has done such signal service to our Indian Empire as Coopers Hill.

Yours faithfully,

JOHN PENNYCUICK, Col. R.E. (late President R.I.E.C., Coopers Hill).

Camberley, April 2.

With regard to the Report itself, which contains the evidence taken by the Board of Visitors, we have received the following from a Correspondent.

After a good deal of pressure both from within and from without the Houses of Parliament, the Secretary of State for India agreed to hold an inquiry into the condition into which the Royal Indian Engineering College at Coopers Hill has fallen under the present *régime*. This inquiry was to be held by a more or less newly constituted body. Lord George Hamilton, however, declined to submit the question of the dismissal of seven of the professors and teachers to an independent body, but he offered to allow the Board of Visitors to hold an inquiry into the justice of the sentences they had themselves pronounced. Adopting the principle familiar to readers of "Through the Looking-Glass," the Secretary of State permits first the judgment and then the trial. On the same principle, the Board of Visitors, into whose competency it is perhaps the most important matter of all to inquire, having acted as judges, not to say executioners, now appear in the *rôle* of prosecuting counsel.

The duties of the Board of Visitors of Coopers Hill seem nowhere to be very clearly defined. But by all analogy the staff of the College should have the right to appeal to the Board, and such an appeal should be listened to with impartiality. The Blue-book issued on April 1, which contains the account of the inquiry, shows, however, the very reverse of a judicial spirit. One of the disadvantages of the method of sentence first and trial afterwards is that instead of making "the punishment fit the crime" it becomes imperative to make the crime fit the punishment, and this the Board of Visitors have most sedulously attempted. They evidently felt they must "save their face" at no matter what cost to the institution whose interests they are supposed to protect.

Throughout the inquiry the dismissed professors and teachers were subjected to a hostile examination which contrasts most strangely with the friendly tone adopted to the president of the College and to other members of the staff, except when the evidence of the latter tended in favour of their dismissed colleagues and against the proposals of the president. The inquiry was rendered nugatory by the rules laid down for its conduct by the India Office. It was ordered that the evidence of each member of the staff should be rigidly restricted to the effect of the proposed changes on the teaching of his own subject and on himself personally, thus preventing material evidence being given on many points of vital importance to the welfare of the College. The Board of Visitors further limited the oral evidence by restricting the staff to the answering of certain questions prepared by the Board. The aim of Sir Charles H. T. Crosthwaite, the chairman of the Board, was apparently to make each of the gentlemen dismissed admit that his retirement was for the benefit of the College. Evidence was continually ruled out because, in the opinion of the chairman, it was of a personal nature; yet Colonel Ottley was allowed to indulge in personalities to an almost unlimited extent.

Throughout the inquiry the Board made little or no attempt to decry the ability or the efficiency of the gentlemen concerned. That was an impossible line, but their attitude throughout was one of

> "Willing to wound, and yet afraid to strike,
> Just hint a fault, and hesitate dislike."

Evidence exists both in the report of the inquiry and elsewhere that some at least of the Board were unacquainted with the contents of the report contained in the first Blue-book, a report purporting to have been drawn up by themselves. This is possibly to be accounted for by the indecent haste with which that document was considered and signed. More than one member of the Board was unaware that he had recommended such wholesale dismissals. The chairman and Sir W. S. S. Bissett express ignorance of the recommendation of the Board that the professor of electrical engineering should teach chemistry and physics in addition to his own subject, and of the fact that this extraordinary arrangement has had the approval of Lord George Hamilton. The Board knew so little of the staff of the College that they inquired after an instructor who has been dead for some years.

A careful examination of the Blue-book and of the minutes of the evidence reveals a wholesale repudiation by the Board of its previous recommendations. They repudiate the time-table incorporated in the first Blue-book and recommended for adoption by themselves. Perhaps the rejection of this document is the wisest thing the Board has done. They repudiate their own arrangement for the teaching of physics and electrical engineering. They repudiate their own arrangement for the teaching of mathematics, and they repudiate their own arrangement for the teaching of engineering.

One of the saddest features of the whole inquiry is the persistent effort made by both the Board and the president to belittle the status of the College. Coopers Hill in the past has stood high amongst the few institutions for scientific education in this country. It has done a great public service to India, and the prestige attached to its name is highly valued by the Government *in* India. Yet throughout the inquiry the Board compare it to a school, or to a technical college. Sir William Preece finds its nearest analogy in a

Metropolitan polytechnic. Finally, the president is desirous of following the lines adopted at Woolwich and Sandhurst, oblivious of the fact that these are military institutions and that Coopers Hill is a civil scientific College. The proper arrangement for the conduct of such a college as Coopers Hill is, in the opinion of Colonel Ottley, that there should be no intercommunication among the staff, but that each member of the staff should communicate alone with the president. The danger of this system of private conferences as leading to misrepresentation is exemplified by the case of Prof. Hearson, whose private consultations with the president are presented in such an extraordinary light by Colonel Ottley (Blue-book, p. 54). It is probably due to this that Prof. Hearson has been dismissed, though the reason adduced by the president was that Dr. Brightmore was debarred from teaching hydraulics, "his strongest subject," because that subject had been allotted to Prof. Hearson. There is, however, conclusive evidence that both professors were desirous of effecting an interchange of work by which hydraulics would have been handed over to Dr. Brightmore. This evidence the Board of Visitors ignore. Another result of this plan of separate conferences has been shown during the past year. The College has been divided into a series of separate camps. Tempted by the secret offers of the president, some of the junior members of the staff have consented to supplant their seniors for the modern equivalent of a mess of pottage, which appears, in this instance, to be something under 100*l.* a year.

The only charge against the College which appears in the report—and if any other existed we may feel sure the Board of Visitors would have set it forth—is that certain of the telegraph men have been found to be unsatisfactory, and that in some respects the telegraph branch might be improved. No fault of any kind is found with the training of the engineering students, who form by far the larger part of what is essentially an engineering college.

The criticisms on the telegraph men, of whom there are about three a year, is contained in Appendix 12 of the Report, pp. 131–146; and Mr. Pitman, who writes therein, expressly states that his "object is not to unduly criticise the course of instruction at the Coopers Hill College, *which has supplied the Department with so many excellent officers*,[1] but to bring to the notice of the responsible authorities that it would be possible to greatly improve the course of instruction and turn out officers with a greater knowledge of the theory and practice of Indian telegraphy than they can now obtain." This report, which is obviously intended, not as an adverse criticism, but as a friendly suggestion to the staff for improvement in details, expressly states that all the physical laboratory work (for which Mr. Shields is responsible) is excellent.

We have searched the Blue-book in vain for evidence that the Board of Visitors have tried to discover whether any of the suggestions made have been adopted, though Mr. Shields does manage to tell them that those referring to his part of the work have been adopted as far as time permits. And yet Mr. Shields is sent away. We happen to know that it was absolutely necessary for the Board to get rid of Mr. Shields because his successor had already been appointed! and because, moreover, Colonel Ottley had informed that successor, in the interval between the dates of the correspondence between Sir Wm. Anson and Lord George Hamilton (which was published in the daily papers) and the beginning of the inquiry, that whatever happened his appointment was secure! The bias of the Board is further shown by their conducting no inquiry into the admittedly excellent electro-technical course taken by Mr. Shields with some of the third year students.

[1] The italics are ours.

The defects of the telegraph students are not due to this or that part of the course being capable of slight improvement, for it is cordially admitted that many of them are excellent officers. The real reasons are given on pp. 121, 122. The calibre of some of the men during recent years has been exceptionally low, and owing to a variety of circumstances the abler men have not chosen to take telegraph appointments. This year, however, the standard is higher, and unless the break in their work, caused by the extraordinary plan adopted by the India Office of dismissing half the staff in the middle of the session, has too disastrous an effect on the students, they should take a high place in the service.

So far, therefore, from the indictment being justified that the College must be reformed or abolished, we can confidently assert that very few colleges, if subjected to such a hostile criticism as has been applied to Coopers Hill both by the president and by the Board, could show so clean a record.

A grave injustice has been done, not only to the seven gentlemen dismissed, but to all those whose services are "for the present" retained and to all who take part in the higher education of the country. The Board of Visitors have dropped their plea of economy because the changes have been shown not to be economical. They have dropped their plea of increased efficiency because it is impossible to maintain that to dismiss a man with Prof. Hearson's reputation and to replace him by a man of the reputation of Dr. Brightmore (who has not hesitated to inform the Board that he is unable to maintain discipline in his class) makes for efficiency. The Board of Visitors have, in fact, no plea to put forward for the action they have taken. They have relinquished their powers of judgment to a military autocrat who, backed up by other retired officials at the India Office, has absolute power over the destinies of the entire staff at Coopers Hill. Recent events in this country have not increased the faith of the people in the ability of either our public offices or of our army officers. Military methods have been shown to be imperfect and the scientific and educated opinion of the country will be slow to recognise the advisability of extending them to such institutions as the Engineering College at Coopers Hill.

NOTES.

As already announced, a meeting of the International Association of Academies will be opened at Paris on Tuesday next, April 16, in the rooms of the Institute of France. The following is a list of delegates appointed to represent the various academies which will constitute the Association:—Amsterdam: Prof. H. G. van de Sande Bakhuysen, president of the physico-mathematical section of the Academy; Prof. H. Kern, president of the section of letters; Prof. J. de Goeje. Berlin: Prof. H. Diels and Prof. W. Waldeyer, permanent secretaries of the Prussian Royal Academy of Sciences; Prof. R. Helmert; Prof. J. H. van 't Hoff; Prof. T. Mommsen; Prof. E. Sachau. Brussels: Lieut.-General de Tilly; Prof. P. Fredericq. Budapest: Prof. C. Than; Prof. I. Goldziher. Christiania, not yet announced. Göttingen: Dr. E. Ehlers and Dr. F. Leo, secretaries of the Society; Prof. E. Riecke. Copenhagen: Prof. J. L. Heiberg; General G. Zachariæ. Leipzig: Prof. W. His; Prof. A. Fischer; Prof. H. Gelzer. London: Sir Michael Foster and Prof. A. W. Rücker, secretaries of the Royal Society; Dr. T. E. Thorpe, foreign secretary of the society; Sir Norman Lockyer; Sir Archibald Geikie; Prof. A. R. Forsyth; Prof. E. Ray Lankester; Prof. A. Schuster. Munich Prof. W. Dyck; Prof. F. Lindemann; Prof. K. Krumbacher. Paris, Academy of Inscriptions and Belles Lettres: Count De Lasteyrie, president; MM. P. Berger, vice-president;

H. Wallon, permanent secretary; L. Delisle; G. Boissier; Bréal; Barbier De Meynard; Senart; E. Müntz. Academy of Sciences: MM. Fouqué, president; Bouquet de la Grye, vice-president; Berthelot and Darboux, permanent secretaries; Marey; H. Poincaré; Moissan; Lannelongue. Academy of Moral and Political Sciences: Count de Franqueville, president; G. Picot, permanent secretary; Gréard; Glasson; Lachelier; Sorel; Boutroux. St. Petersburg: MM. Famintzin; Backlund; Oldenbourg; Kouliabko. Rome: Prof. S. Cannizzaro; Prof. A. Mosso; Prof. I. Guidi. Stockholm: Prof. G. Retzius, president of the Academy of Sciences. Washington: Prof. G. L. Goodale. Vienna: Prof. Victor von Lang, general secretary of the Academy of Sciences; Prof. T. Gomperz; Prof. Leopold von Schroeder; Prof. J. Karabacek; Prof. J. C. Zirecek; Prof. A. Rollett; Prof. G. Tschermak.

MR. L. DE NICÉVILLE, who has for many years been well known by his published work on Indian and Malay Lepidoptera, has been appointed entomologist in the Indian Museum, Calcutta.

PROF. EUGEN WARMING AND DR. VICTOR MADSEN have been appointed to the Danish Geological Survey, and Dr. H. Topsöe has retired from the Survey.

THE death from cholera of Mr. G. F. Reader, of the Geological Survey of India, took place at Madras on March 12. Mr. Reader was appointed as a specialist in coal mining in 1899, and for the last five months of his life also officiated as Government mining inspector.

REUTER'S correspondent at Constantinople states that the sharp earthquake experienced there on March 30 occurred at five minutes past nine in the morning. The movements observed were in the direction from south-west to north-east and lasted nearly five seconds.

MR. W B. TRIPP, writing from Isleworth, says that on April 4, about 10 p.m., a fine display was observed of lunar halo with horizontal ray on a level with moon and two paraselenæ (or mock moons) at its intersection with the halo, which remained all the evening while the paraselenæ soon disappeared.

THE subjects of the Walker prizes in natural history to be awarded by the Boston Society of Natural History, Massachusetts, U.S.A., are as follows:—For 1901: Monograph on any problem connected with, or any group belonging to, the North American fauna or flora; for 1902: (1) nuclear fusions in plants; (2) the fate of specific areas of the germ of chordates, as determined by local destruction; (3) the reactions of organisms to solutions, considered from the standpoint of the chemical theory of dissociation.

AN International Maritime Congress will be held at Monaco on April 12–15, under the presidency of M. J. Charles-Roux. The congress will discuss, among other questions, those of assistance to the shipwrecked, the international unification of coast-lights and buoyage, maritime meteorological observations, wireless telegraphy, marine pigeon-post, international maritime tribunals, and a scheme for the creation of a permanent international maritime bureau. The last-named project aims at the international discussion of maritime questions by a permanent and official body.

THE Director of the Missouri Botanic Garden has recently called attention to the facilities offered by that institution for botanical research. The garden owes its foundation to the munificence of Henry Shaw, and the good work which he inaugurated has resulted in the formation of a splendid collection of plants in the garden and in the herbarium, together with an adequate library without which they would lose much of their value. The collection of books is especially rich in systematic works, and thus affords opportunities for study of the American flora and of its relations with that of other countries. The Director, Dr. Trelease, extends also a courteous invitation to those who may desire to make use of the collections for physiological or other objects, suggesting that provision may be made to suit the requirements of those who desire to engage in such investigations. The growing prominence which is being given to research, and the spirit which impels it, affords one of the surest guarantees for greatness of the intellectual and material future which lies before a strong and virile community.

THE Brussels Academy of Sciences announces the following prize subjects for 1901:—New researches upon the compounds formed by the halogens between themselves (800 francs); the determination of the form of the principal terms introduced into the formulæ of nutation in obliquity and longitude by the elasticity of the earth's crust (800 francs); historical and critical discussion of Weber's experiments on unipolar induction, and new experiments bearing upon the laws and interpretation of this physical fact (800 francs); a contribution to the study of mixed forms with a number of series of variables, and the application of the results to the geometry of space (600 francs); history of researches on the variation of latitude, and a discussion of the interpretations of this phenomenon (600 francs); investigations of the physiological *rôle* of albuminoid substances in the nutrition of animals or plants (800 francs); new researches on the organisation and development of Phoronis, and the relations existing between the animals Rhabdopleura and Cephalodiscus, and the class to which the name Enteropneusta has been applied (1000 francs); description of simple substances, sulphates and binary compounds of Belgian soil (800 francs); researches on the influence of external factors on karyokinesis and cellular divisions in plants (800 francs).

THE expeditions which will start for the Arctic regions during 1901 are described in the U.S. *Monthly Weather Review* as follows:—(1) The Zeigler-Baldwin, to be led by Mr. Evelyn B. Baldwin, who lately resigned from the Weather Bureau for this purpose, the funds to be contributed by Mr. William Ziegler, of New York. (2) A Russian expedition, commanded by Vice-Admiral Makaroff, in a vessel constructed to push its way through ice fourteen feet thick. (3) A Canadian expedition, in charge of Captain Bernier, in the *Scottish King*. (4) A German expedition, plans not yet published. (5) A joint expedition by Dr. Nansen and the Duke of the Abruzzi. (6) Peary and his companions will finish the exploration of Grinnell Land and return home. (7) Dr. Robert Stein and his companions will complete the exploration of Ellesmere Land. (8) A relief expedition to Franz Josef Land, under the command of Captain Stoekken, and apparently at the joint expense of Nansen and Abruzzi. (9) Baron Toll will send a party from the Kara Sea eastward along the Siberian coast. Captain J. E. Bernier, of Quebec, proposes to travel by the route taken by the wreck of the *Jeannette*, with dogs, reindeers, and sledges, over the ice from the Lena or Bennett Island region. The trip may last two and a half years.

ON Tuesday next, April 16, Dr. Allan Macfadyen will deliver the first of a course of six lectures at the Royal Institution on cellular physiology, with special reference to the enzymes and ferments. On Thursday, April 18, Mr. Roger Fry will begin a course of two lectures on naturalism in Italian painting, and on Saturday, April 20, Mr. John Young Buchanan will deliver the first of a course of three lectures on climate: its causes and its effects. The Friday evening discourse on April 19 will be delivered by Prof. J. J. Thomson, his subject being "The Existence of Bodies smaller than Atoms."

THE dispute between the London United Tramways Company and the authorities of Kew Observatory has at last been settled. The tests made at the Board of Trade trial, referred to in our issue of March 21 (p. 499), having shown that the electrical working of the tramway from Hammersmith to Kew will interfere with the magnetic work done at the Observatory, the Tramways Company have agreed to pay a considerable sum towards the cost of removing the instruments to some more suitable site. The electric cars have in the meantime started running. The cars, which are much superior to the old horse trams in comfort, run smoothly and rapidly, taking about five and twenty minutes over the journey from Hammersmith to Kew. The overhead wires, though they certainly do not improve the appearance of the street, cannot be said to be excessively ugly; even at Young's Corner, Chiswick, where the branch line runs off to Shepherd's Bush, and where, consequently, the number of wires is considerable, the effect is not so bad as to be an eyesore. The route, leading direct to Kew Gardens, is a popular one with Londoners anxious to get into the country, and they seem already to appreciate the benefit of the electric trams; it is to be hoped that the system will undergo rapid expansion and extension and give Londoners a cheap, quick and easy method of getting really out of the town.

WE have received a copy of *Traction and Transmission*, a monthly supplement to *Engineering*, which makes its first appearance this month. Although the multiplication of technical journals is not a thing to be indiscriminately encouraged, the possibility of keeping pace with all the modern papers becoming daily more difficult to the engineer, there can be no doubt there is ample room at the present time for a magazine devoted to these subjects. England has been at last obliged to set itself seriously to the consideration of the means of relieving the overcrowding and congestion of traffic in the large towns, and the appearance of this paper, at a moment when the attention of every one is being directed to big schemes for traction and the transmission of power, is therefore very opportune. The first number, which is almost wholly devoted to electric traction, contains, amongst many others of great interest, articles on the standardisation of electrical apparatus, by Mr. H. F. Parshall, on the conveyance of goods on electric trolley lines, by Mr. A. H. Gilbings, and on the much vexed question of the education of the electrical engineer, by Mr. R. A. Raworth. The paper is got up in sumptuous style, being printed in very large type on extra thick paper and illustrated by a number of capitally-executed plates and diagrams.

THE U.S. *Monthly Weather Review* for December last contains the report of an interesting investigation by Dr. O. L. Fassig on the relation between summer and winter temperatures, with the view of finding, for instance, whether an extremely hot summer precedes a cold winter. The basis of the investigation was an accurate daily record of weather from 1817 to the present time. The investigation shows that neither warm nor cold summers have any more relation to the succeeding winter temperatures than the normal summers have, and that, generally speaking, there is no regular alternation or period in atmospheric temperatures.

The Summary of the Weekly Weather Report for the year 1900, published by the Meteorological Council, contains the mean values of rainfall and temperature for the principal wheat-producing and grazing districts of the British Islands for each five years of the thirty-five yearly period, from 1866 to 1900. The rainfall for the British Islands generally in the year 1900 was 3·7 inches above the average for the whole period. The greatest excess was 16·3 inches in the west of Scotland; in the north of Scotland the excess was 10·2 inches, and in the south of Ireland 7·9 inches. The only districts in which there was a deficit were the east and south of England, being 1·3 inch in both cases. The driest year, for the whole kingdom, was 1887 (25·8 inches), and the wettest 1872 (49·1 inches). The mean temperature during 1900 was, on the whole, 0°·4 in excess of the average, the greatest departures being +1° in the east and south of England. The coldest year was 1879 (46°·2) and the warmest 1868 (50°·4) for the British islands generally.

AT South Pasadena, California, the large reflector shown in the accompanying illustration, from the *Scientific American*, has been erected, and the solar rays concentrated by it are utilised to produce steam in a boiler at 150 lbs. pressure and drive a motor of fifteen horse-power. The reflector is 36 feet 6 inches in diameter at the top and 15 feet at the lower part. The inner surface is made up of nearly eighteen hundred small mirrors, all arranged to bring the sun's rays to one focus, at which spot a boiler 13 feet 6 inches in length and holding one hundred gallons of water is suspended. The reflector is mounted upon the same principle as that adopted for large telescopes, and is kept facing

the sun by a driving clock. The steam from the boiler is carried to the engine by means of a flexible phosphor-bronze tube, and returns from the condenser to the boiler, so that the water supply in the boiler is kept up automatically. The temperature at the focus of the reflector is sufficient to melt copper, and a pole of wood thrust into it burns like a match. The motor is used to pump water from a well and appears to work satisfactorily. As the skies of Southern California are remarkably free from clouds, and millions of square miles of arid lands are only awaiting the flow of water to be converted into fertile tracks, the solar motor may provide a practicable means for pumping the water and thus leading to the development of the country.

FOR sixty-seven years the Royal Observatory of Belgium has published an *Annuaire* dealing both with astronomy and meteorology, but from the present year each of these services has its own *Annuaire*. Twenty years ago M. Houzeau made a separation of these sciences, so far as the *Annales* are concerned; the division is now complete in everything except the administration. The *Annuaire Meteorologique* for 1901 contains a large

amount of useful information, including the average mean temperature and the mean maximum and minimum temperature at Brussels (or Uccle) for each day of the year, and the monthly means and extremes of all the principal meteorological elements since 1833. There are several articles of special interest, including one by M. J. Vincent on the history of meteorology in Belgium from the earliest times until the establishment of the Academy of Sciences at Brussels in 1773. The next *Annuaire* will continue the sketch from the creation of the Academy until the foundation of the Royal Observatory in 1833.

THE Committee of the Bristol Museum record in their annual report the extensive operations carried on at Brislington, near Bristol, where the remains of a Roman villa have been found. The extensive foundation walls of the villa were laid bare, showing the plan of its construction and many of its domestic features. In addition to two fine mosaic pavements, a great variety of relics of the Roman period were discovered.

THE "Physical Geography of the Texas Region," by Mr. Robert T. Hill, forms Folio 3 of the Topographic Atlas of the United States, issued by the U.S. Geological Survey (1900). It is a finely-printed work, illustrated with numerous maps and beautiful photographic representations of topographic forms, mountains, plains and scarps, rivers and canyons. In the descriptive text the author deals, for the most part, concisely with his subject, showing, first of all, the relations between the geological formations and the scenery, and then describing the principal features.

THE Maryland Geological Survey, which is under the direction of Dr. Wm. Bullock Clark, has just commenced the issue of a series of reports on the physical features of the counties of Maryland. The first report on Allegany County may be taken as a sample of what can be done by an energetic and well-equipped staff. It occupies 323 pages, is printed in remarkably clear type, and is illustrated with numerous diagrams, pictorial views and maps. Accompanying it is a folio atlas, with a colour-printed geological map on a scale of 1 inch to a mile, and other topographic maps. Many experts aid in the descriptions of various subjects, such as physiography, stratigraphy, mineral resources, soils, climate, hydrography, forestry, and fauna and flora. The county, indeed, is one highly favoured, few regions being more salubrious or more picturesque. Along its full length from east to west the Potomac River meanders through a district of rich farming lands and wild mountain scenery. Silurian, Devonian, Carboniferous, Permian and Pleistocene formations are met with, and the history of research among these strata is fully recorded. The leading characters and many details concerning the formations are given, though with too scant particulars of the fossils to please those who seek comparisons with equivalent strata elsewhere. The rocks grouped as Permian follow the Carboniferous conformably. They comprise shales and limestones with unimportant sandstones and coal-beds, and their fossils have yet to be described. To those residing in Allegany County this admirable memoir cannot fail to be of the greatest interest and service.

THOSE who have visited the Bankfield Museum at Halifax are aware of the improvements effected in the ethnographical section by the untiring industry of Mr. H. Ling Roth, the honorary curator, who has, in addition, just issued a pamphlet on the Fijian Collection. This excellent little guide of twenty-seven pages contains forty-four illustrations, mostly of specimens in the collection. It forms an interesting sketch of Fijian ethnography, written with that carefulness of detail which students have learnt to expect from Mr. Ling Roth. As coloured designs on bark cloth are found in some parts of New Guinea where direct Polynesian influence is entirely out of question, there seems no reason to believe, as Mr. Ling Roth suspects, that Fijian *masi* or *tapa* is a "Polynesian institution introduced among this Melanesian people." The same argument applies, though perhaps not so conclusively, to tatuing.

WHERE the Thompson and Fraser rivers meet at Lytton in Southern British Columbia has always been an important site of the Indians, as the ancient burial grounds and village sites testify. The late Dr. G. M. Dawson first described the remains in 1891, but recently the Jesup North Pacific Expedition made a series of explorations in this vicinity, of which an abstract has been described by Harlan J. Smith in the *Memoirs* of the American Museum of Natural History, vol. ii. part iii. (*Monumental Records*). The prehistoric culture resembles that of the present inhabitants of the interior of British Columbia. The mode of life of the prehistoric tribes, their utensils and even their customs must have been practically the same as those of recent Indians. There are, however, a few slight differences; the ancient type of pipe resembles the prehistoric pipe of Oregon and California, while the recent pipe is practically of the same type as that found on the plains. The potter's art was then, as now, unknown. On the whole the prehistoric culture of the interior of British Columbia shows greater affinity to that of the western plateaus than to that of the North Pacific coast.

MR. C. D. CHILD, writing in the *Physical Review* for February, describes some experiments made with the new method for determining the velocity of ions, recently suggested by Prof. J. J. Thomson. The method in question "is to produce the ions in one region and measure the electrical intensity at two points where there is no production of ions, but to which ions of one sign only can penetrate under the action of the electric field." The author shows by an application of Prof. Thomson's method that the velocity of the positive ions drawn from a Bunsen burner is approximately 2·2 cm. per sec. for potential gradient of 1 volt per cm., and that for negative ions 2·6 cm. Further, in the case of an unlimited supply of ions, if the discharge takes place between two regular surfaces, the velocity may be determined by simply measuring the current per unit area and the difference of potential between these surfaces, and if the surfaces are not at all regular the relative velocities of the positive and negative ions may be determined by comparing the positive and negative currents.

IN a paper on stationary motions, published in the *Atti dei Lincei*, x. 5, Signor T. Levi-Civita has endeavoured to furnish a more precise definition than commonly exists of the conception of stationary motion. Routh's definition, taken in its purely formal aspect, leads to the conclusion that by a proper choice of variables any motion may be regarded as stationary. On the other hand, experience teaches us that certain motions possess peculiar characters of simplicity and regularity which distinguish them clearly from other motions, and, moreover, Routh's examples show that in certain cases his definition actually does distinguish stationary motions (in the physical sense) from non-stationary motions. The author considers that the distinguishing characteristic in such cases is that the integrals or invariable relations which determine stationary solutions are always *uniform* in the sense considered by Poincaré. According to Routh, a stationary motion Σ is characterised by the property that if the conditions are equally modified at any two instants, t', t'', the disturbed motions Σ', Σ'' present relations such that under a certain condition they may be regarded as equivalent. Now Signor Levi-Civita considers that an analytical condition which is not uniform has no physical interest, and he is of opinion that Routh's definition of stationarity should be completed by adding the proviso that the relations between two disturbed motions, Σ', Σ'', should be uniform. As an example,

it follows that the problem of n bodies does not admit of any forms of motion absolutely stationary beyond the particular solutions of Laplace, in which the bodies rotate uniformly, maintaining an invariable (plane or rectilinear) configuration. On the other hand, the chief problems of ordinary dynamics conform to the property in question.

We learn from the April number of the *Entomologists' Monthly Magazine* that the late Mr. Lennon's collection of British Coleoptera has found a permanent home in the Edinburgh Museum of Science and Art. Its richness may be gathered from the circumstance that the number of species from the Solway district alone is estimated at more than twelve hundred.

In addition to several papers dealing with abnormalities in human anatomy and others on ethnology, the *Proceedings* of the Anatomical and Anthropological Society of the University of Aberdeen for 1899-1900 contains an abbreviated report of a lecture delivered before the University by Dr. A. Keith, on the relations of man to the higher Primates. The lecturer expressed his opinion that the gorilla and chimpanzee are co-descendants of an early Miocene anthropoid, for which the name Protroglodytes was suggested. It was estimated that more than five million years have elapsed since the separation of the human stock as a distinct form.

The osteology of the woodpeckers forms the subject of a paper by Dr. R. W. Shufeldt in the October-December issue of the *Proceedings* of the American Philosophical Society. As the result of his investigations, the author concludes that these birds are more nearly related to the Passeres than to any other group, and that both are probably divergent branches of a single ancestral stock. In a second communication to the same journal, Dr. Shufeldt treats of the skeleton of the owls, and arrives at the conclusion that there is no marked affinity between that group and the diurnal birds of prey. Rather, he thinks, there is a relationship, although a remote one, between the owls and the nightjars, the South American oil-bird (Steatornis) and the Australasian Podargus being the members of the latter group in which the evidence of strigine affinities is most conspicuous.

The journal last quoted also contains an interesting communication by Mr. R. H. Mathews, dealing with the origin and customs of the Australian aborigines. It is argued that the Australians reached their present home by way of the Malay Islands, but that the immigration has taken place at more than one epoch, the later immigrants being of a higher grade than their predecessors. The earlier immigrants are considered to have been of the Melanesian type, and their unmodified descendants were the now extinct Tasmanians. The later invaders, on the other hand, never reached Tasmania, which had, at the time of their arrival, become insulated. "There is nothing unreasonable," adds the author, "in the assumption that these invaders and the native tribes of the southern portion of India are the descendants of a common stock—the Australians, owing to their long isolation, having retained the primitive character of their Neanderthaloid ancestors, while the later Indian tribes have attained a higher grade of evolution." Possibly this may be the real solution of an extremely puzzling ethnological problem.

The *Century Magazine* for April contains an excellent and fully illustrated popular account, by Dr. L. O. Howard, the chief entomologist of the U.S. Department of Agriculture, of the recent investigations connecting the propagation of malaria with mosquitoes of the genus Anopheles. The author first of all dwells upon the great prevalence of malaria in certain parts of the world. Although in temperate regions the mortality from this disease is not high, in one year in the United States the deaths due to malarial fever were 3976 per 100,000, and in a later year 2673 per 100,000. In Italy the average death-rate from this cause is 15,000 annually, while in India five million deaths were ascribed to "fever" in 1892, and in Italy two million persons suffer annually in one way or another from malaria. The malaria-producing species are then described, after which comes a description, with illustrations, of the development of the malaria-parasite in the red blood corpuscles and in the body of the Anopheles mosquitoes. The article concludes with a brief reference to the evidence now being collected to connect yellow fever with a mosquito. Instead of belonging to Anopheles, the suspected insect pertains to the genus Culex (or perhaps represents a genus by itself); and it is considered probable, if the suspected connection between this insect and yellow fever be verified, that the fever germ will prove to be a protozoon, that is to say, an animal, and not a bacterion or vegetable organism. The experiments in question were made during last summer and winter by the U.S. Army surgeons in the hospitals at Cuba; and they tend to show with a reasonable degree of certainty that mosquitoes which have bitten patients suffering from yellow fever may, and do, convey the disease by biting healthy persons.

We have received the annual report of the Indian Museum, Calcutta, for the year ending March 31, 1900, and are pleased to learn that considerable progress has recently been made in the development of that institution. Owing to the removal of the offices of the Geological Survey to another building, four additional galleries are available for exhibition, and the superintendent, Major Alcock, reports that three of these have been already opened to the public. They have respectively been filled with reptiles, fishes and insects, arranged with special regard to the requirements of the student of the Indian fauna. The transfer of these specimens has allowed a much-needed expansion of some of the other groups. A very large proportion of the work of the staff has, indeed, been devoted to the improvement and rearrangement of the exhibition series, which, as the superintendent remarks, is that portion of the museum whereby progress is gauged by the public, and where the influence of the museum is most exerted. It may interest museum officials in this country to learn that most of the fishes in the Indian Museum are now coloured in imitation of their natural tints and that a large proportion of the reptiles and amphibians are represented by coloured clay models. Almost the only thing that Major Alcock has to lament is the circumstance that the post of naturalist to the surveying ship was vacant during the greater part of the year, in consequence of which the museum's list of acquisitions fell much below the normal.

The second part of a bibliography, guide and index to bacteriological literature, belonging to vol. i. (Bacteria) of "The Scientific Roll" has been received. The magazine, which is conducted by Mr. Alexander Ramsay, contains lists of papers published from 1876 to 1892 (both inclusive), arranged in each year alphabetically according to authors' names.

A new edition (the third) of Mr. W. W. Rouse Ball's inspiring "Short account of the History of Mathematics" has been published by Messrs. Macmillan and Co., Ltd. The work originally appeared in 1888 and was described in detail in these columns (vol. xxxix. p. 265). The present edition has been revised but not materially altered.

Four parts of the first volume of *Proceedings* of the University of Durham Philosophical Society, containing papers brought before the Society in the years 1896-1900, have been received. As a record of the Society's contributions to knowledge during the first four years of its existence, the *Proceedings* are very creditable. Many of the papers contain the results of

research, and others deal with various aspects of science descriptively. Such a society is a centre of beneficial influence, for it encourages investigation, affords facilities for the communication of facts and ideas, and promotes the friendly intercourse which broadens the views and sympathies of workers in different fields.

INCREASING interest in physical chemistry is shown by the fact that Prof. Walker's "Introduction to Physical Chemistry" (Macmillan), which was published towards the end of 1899, is already in its second edition. The book, which contains a full discussion of the chief principles of modern physical chemistry and shows their application to ordinary laboratory chemistry, has already been noticed in these columns (vol. lxii. p. 76, May 1900). Among other new matter in the new edition are accounts of "Berthelot's method for determining exact molecular weights from the limiting densities of gases, Traube's volume researches, and the position of the recently-discovered atmospheric gases in the periodic system."

IN the current number of the *Berichte*, Messrs. Pictet and Rotschy give an account of the isolation of three new alkaloids from tobacco. Up to the present only a single organic base, nicotine, has been found in tobacco. In most plants producing alkaloids several bases usually occur together, and as it appeared unlikely that the tobacco plant should prove exceptional in this respect, a large quantity of tobacco extract was worked up, with the result that three new bases were discovered, to which the names nicoteïn, nicotellin and nicotimin are given. Of these, the last is associated with the crude nicotine, with which it is isomeric, differing, however, in being a secondary base and forming a nitrosamine by means of which it can be separated from the nicotine, in spite of the fact that it is present in very small amount in the crude base. The nicoteïn contains two atoms and the nicotellin four atoms of hydrogen less than nicotine.

THE additions to the Zoological Society's Gardens during the past week include a Patas Monkey (*Cercopithecus patas*) from West Africa, presented by Mr. H. Plange; a Diana Monkey (*Cercopithecus diana*) from West Africa, presented by Mrs. Yorke; a Bonnet Monkey (*Macacus sinicus*) from India, presented by Mr. W. K. Edwards; a Common Otter (*Lutra vulgaris*), British, presented by Mr. W. Radcliffe Saunders; a Maximilian's Aracari (*Pteroglossus wiedi*) from Brazil, presented by Mrs. J. Rose; a Common Viper (*Vipera berus*), British, presented by Mr. G. Leighton; two Spanish Cattle (*Bos taurus*) from Spain, a Black-faced Kangaroo (*Macropus melanops*) from Tasmania, a Yellow-footed Rock Kangaroo (*Petrogale xanthopus*) from South Australia, a Grevy's Zebra (*Equus grevyi*) from Southern Abyssinia, three Zebus (*Bos indicus*) from India, two Nubian Goats (*Capra hircus*) from Nubia, five four-horned Sheep (*Ovis aries*) from St. Kilda, two Somali Ostriches (*Struthio molybdophanes*) from Somaliland, deposited; a Kestrel (*Tinnunculus alaudarius*), British, presented by Mr. F. Layer.

OUR ASTRONOMICAL COLUMN.

THE SPECTRUM OF NOVA PERSEI.—Prof. Vogel, in a recent communication (*Sitzber.* d. k. Akad. der Wiss. zu Berlin, March 21, xvi.), gives the results of a discussion of the Potsdam observations of Nova Persei. Prof. Vogel considers that the spectrum can only be explained on the hypothesis of Wilsing. The immense perturbations in the star give rise to great differences of pressure in the layers of the materials composing the Nova, and these differences account not only for the presence of the bright and dark lines, but their great breadth. Prof. Vogel does not think that there is any reason to assume that the apparent great displacement of the dark lines is the consequence of a large motion deduced on the principle of Doppler. This displacement he accounts for on the supposition of the overlapping of the broad dark band over the bright band, the great pressure of the substance giving the bright band being more strongly developed on the red side, thus allowing the dark band to appear more prominent on the violet side.

STONEHENGE AND OTHER STONE CIRCLES.

TWO interesting papers on stone circles, by Mr. A. L. Lewis, have recently been published by the Anthropological Institute. One dealing more particularly with the stone circles of Scotland occurs in the *Journal* of the Institute (vol. xxx. New Series, vol. iii. 1900), and the other, on the damage recently sustained by Stonehenge, appears in *Man*—the monthly record of anthropological science published under the direction of the Institute. We reprint the latter paper, with the two illustrations accompanying it, and are glad to acknowledge the courtesy of the Institute in permitting us to do so. And here it will not be out of place to remark that both the *Journal* and *Man* are full of papers and notes of interest to every one devoted to the study of the human race in its many aspects. When one considers how little encouragement is given to the science of anthropology in this country, it is really astonishing to see the large amount of excellent material published under the auspices of the Anthropological Institute. The U.S. Bureau of Ethnology have funds to publish magnificent volumes showing the results of ethnological investigations carried on by its officers, but here there is no similar department for the preparation and distribution of such contributions to science, and anything that is done represents the result of private efforts for the advancement of natural knowledge. Even if no assistance is given to systematic anthropological inquiries in our colonies and dependencies, every facility ought to be provided for the publication of facts obtained by observers interested in the characteristics and customs of the races of men.

Mr. Lewis describes, in the *Journal* already mentioned, the observations made by him of stone circles in various parts of Scotland. The condition of some of these monuments of antiquity is deplorable, many of the stones having been shifted and used for all kinds of purposes. At Clava, for instance, we notice that one stone has been shifted to be parallel with a road running across the circle, and another has been placed to form the end of a stone wall. From an examination of a large number of stone circles in Scotland, Mr. Lewis concludes that they may be divided into different types each of which has its centre in a different locality. The types are (1) the Western Scottish type, consisting of a rather irregular single ring or sometimes of two concentric rings. (2) The Inverness type, consisting of a more regular ring of better-shaped stones, surrounding a tumulus with a retaining wall, containing a built-up chamber and passage leading to it, or a kist without a passage. (3) The Aberdeen type, consisting of a similar ring with the addition of a so-called "altar-stone" and usually having traces of a tumulus and kist in the middle. There is reason to believe that most of the circles of these three types were used for burial, if, indeed, that were not their chief purpose, but as there is evidence that all have not been so used, it cannot have been their only purpose. In addition to these three types of circles, there are what Mr. Lewis calls sun and star circles, with their alignments of stones, and apparently proportioned measurements. The stone circles of England appear to refer to the sun and stars more frequently than those of Scotland, where, however, more similar circles may yet be found. The Stonehenge group of stones seems almost to form a class by itself, and Mr. Lewis's description of it, reprinted below from *Man*, describes the present condition of this unique monument.

"The end of the nineteenth century has been signalised by—amongst other things—the fall of a part of Stonehenge, a misfortune which may not be without its compensating advantage if it should be the cause of the necessary measures being taken to preserve what is left of this unique monument in an intelligible condition.

"Stonehenge, it will be remembered, consists of a number of comparatively small stones standing in the form of a horse-shoe with the open end to the north-east, outside which were five "trilithons," or sets of two upright stones, each supporting a huge cross-piece; these were the largest stones of all, and only two sets of them remain complete, the last great change at

Stonehenge having been the fall of one of them in January 1797. Outside these was a circle of small stones, and outside these again a circle of larger upright stones, joined at the top by cross stones; both these circles are so defective, especially towards the south-west, that it has been doubted whether they ever were complete. It is one of the uprights of this outer circle (marked

Fig. 1.—Plan of Stonehenge. A, Stone now fallen. BB, Stones which fell in 1797.
(*Reproduced from "Man."*)

A on the plan—No. 22 on Petrie's plan) that has now fallen inward, carrying with it the capstone which connected it with the adjoining stone, and which has been broken in two by striking in its fall the remains of the trilithon which fell in 1797.

"It is, perhaps, fortunate that these stones have fallen instead of the remaining stone of the central trilithon, the downfall of which has long been expected on account of its leaning position, an occurrence which, if not prevented, will cause much more damage than has been caused for centuries, and the practical question for archæologists is what is to be done to prevent it? Of course, no one advocates "restoration" in the sense of adding new stones to supply the places of those which have disappeared; but, inasmuch as the exact original position of almost every existing stone is perfectly obvious, and inasmuch as exact surveys have been made and published both by Sir Henry James on behalf of the Ordnance Survey,[1] and by Prof. Flinders Petrie,[2] there should be no objection to setting the leaning stones upright, so as to prevent them falling and breaking themselves and others, and to setting up those that are quite fallen, except those that are too much broken to be capable of being joined together. Such fragments should be left where they are, as also should any the precise original position of which cannot be ascertained. Next comes the question of keeping the stones in their position when they have been restored to it; and the best way to do this would be to dig out the whole interior down to the solid chalk, underpinning the stones while the work was going on, and to fill it up with concrete. In the digging out it might be expected that some relics would be found which might throw light on the date if not on the purpose of the monument; but the objection will no doubt be made that future generations might think that the concrete was part of the original work. This would be less likely to happen if the concrete were covered for its better preservation with half an inch of the best asphalte, such as is used in paving the London streets, under which boxes with documents might be buried for the benefit of any future excavators.

"If it were possible to keep things as they are, it might be preferable from an artistic point of view to do so, but it is not possible. If something be not done to prevent them further falls will happen, and where will be the poetry in a shapeless heap of broken stones?

"It must, however, be remembered that Stonehenge, though an object of national concern, is private property."

A plan of Stonehenge is given in the *Times* of Tuesday, April 9, with a description of the condition of the monument and the natural and other causes which threaten to do mischief to it. To protect the monument, Sir Edmund Antrobus is prepared to erect around it, at his own cost, a wire fence 1500 yards in total length.

This course is recommended by the Society of Antiquaries, the Wiltshire Archæological Society, and the Society for the Protection of Ancient Monuments, and the suggestion has the approval of the county council, the district council, and the parish council of Amesbury. The societies further recommend

Fig. 2.—View of Stonehenge from the west. A, Stone now fallen. BB, Stones which fell in 1797.
(*Reproduced from "Man."*)

1 "Plans and Photographs of Stonehenge and of Turnsuchan in the Island of Lewis." 4to. Ordnance Survey: Southampton, 1867.

2 "Stonehenge: Plans, Descriptions and Theories." 4to. London: Stanford, 1880.

the diversion of a grass driving road which now cuts across the earthwork, without prejudice to any legal question.

To prevent other stones from falling it is suggested by the societies mentioned that the trilithon which has slewed round and also a leaning-stone be first examined with a view to maintaining them in safety. It is understood that no excavation beyond what is absolutely necessary will be allowed. This examination will show what can be done and ought to be done with all the standing Sarsens. It is advised that the monolith and lintel, which fell three months ago, be replaced, the companion Sarsen being made safe against the effects of the fall. Further, the societies recommend the erection of the great trilithon which fell in 1797, the exact place of which is known. All the rest they would leave as it is, though in some cases the place of fallen stones is known with fair certainty. The questions of how best to fix more firmly in the ground the stones now standing, and how best to re-erect the two trilithons which have fallen in the last 104 years, is left to engineering experts.

A STUDENT'S DRUM RECORDER.[1]

THIS admirable instrument consists of five parts easily detachable, viz. (i.) an adjustable tripod, which carries on one foot (ii.) a steel bracket for the attachment of the appurtenances incident to an observation; and (iii.) a central adjustable rod so fashioned as to receive (iv.) the drum, the heads of which are widely perforated for purposes of manipulation; and (v.) a clockwork driver, which is keyed at two points for insertion into the head of the rod. The special novelty of the instrument lies in the driver, which is so constructed that when at work it and the drum are together rotated. The driver is, moreover, set in a metal framework supported upon three feet, upon which it rests when not in use, adequately protected. Its working parts are all exposed, and there are no accessories. The arbor of the spring-wheel above, and of the main driving-wheel below, are each so keyed as to fit into the head of the rod or axle, the former being intended for slow motion, the latter for quick. For one winding the drum will run at its most rapid rate for 12–13 minutes, at its slowest for 16–17, allowance being made for adjustment of the wings of the "fly," which as a whole can be itself easily removed to ensure the maximum obtainable speed. The instrument is a triumph of ingenuity and good workmanship, and we have nought but praise to accord it. To produce at little more than one-fourth the price of the conventional drum-recorder a substitute in efficiency its equal, is to deserve well of the scientific public. This drum supplies a want long felt by teachers, and is bound to become popular. We heartily wish it the success it deserves.

FIG. 1.—A Drum Recorder dismounted to show its parts.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

MR. HERBERT F. ROBERTS, instructor in botany in Washington University, at St. Louis, Missouri, U.S.A., has been elected to the chair of botany in the Kansas State Agricultural College.

FOR the last two or three decades the engineering profession of Austria and Hungary spared no efforts to raise the technical institutions throughout those countries to the standard of the universities and to obtain for the former some of the more important academic privileges and powers which the latter have enjoyed since their establishment. The first aim of the leading members of the said profession was that the technical institutions should be authorised by the Government to grant degrees which, from an academic point of view, should be regarded as equal to those granted by the universities. We now notice, therefore, with satisfaction that their endeavours have been finally crowned with the desired success, and that the Minister of Public Instruction in Austria held, on April the 4th, a meeting which was attended by representatives of almost every technical institution in that country, and on this occasion announced the Government's intention of introducing a special statute by means of which the technical high schools should be empowered to confer the degree of Doctor of "Rerum Technicarum" upon students whose scientific attainments entitle them to that distinction. A special examining body will be appointed for that purpose, and some of the examiners, it is urged, should be at the same time members of the teaching staff in connection with some of the universities; the examinations, again, will be conducted on the same lines as those prescribed by the philosophical faculty of a university for the bestowal of the degree of Ph.D. The acquirement of that degree, however, will not—at least for the present—be made compulsory for all students of the technical academies; those, on the other hand, who attain it will, of course, be given special precedence in the case of Government appointments, which are usually accessible to all graduates of the recognised technical institutions by open competition.

SCIENTIFIC SERIAL.

Bulletin of the American Mathematical Society, March.—Prof. T. F. Holgate reports the December meeting of the Chicago section of the Society (December 27 and 28, 1900), and gives abstracts of several of the twenty-two papers which were read. In addition there is printed a paper by Prof. Hathaway on pure mathematics for engineering students, which was followed by an interesting discussion. The subject was treated under the heads (1) its utility; (2) methods of instruction; (3) the course; and (4) the instructor.—A paper read by Prof. Newson, at the February meeting, on indirect circular transformations and mixed groups, is supplementary to a paper entitled "Continuous Groups of Circular Transformations" (which appeared in the *Bulletin* for December, 1897), and deals with indirect circular transformations and the mixed groups obtained by combining these with the direct transformations. Prof. E. W. Brown reviews, at some length, the scientific papers of J. Couch Adams and the lectures on the Lunar theory, (vol. ii. Parts 1 and 2), edited by Profs. R. A. Sampson and W. G. Adams. Then follows, in English, the notice on M. Hermite, by M. C. Jordan, an address delivered at the meeting of the Paris Academy of Sciences, January 21, 1901.—The notes, as usual, cover a wide ground, and there is the usual portion appropriated to new publications.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, March 14.—"On the Ionisation of Atmospheric Air." By C. T. R. Wilson, F.R.S., Fellow of Sidney Sussex College, Cambridge.

In a preliminary note (*Camb. Phil. Soc. Proc.*, November 26, 1900) it was stated that a body, charged with electricity and suspended within a vessel containing dust-free air, loses its charge by leakage through the air. The same conclusion was arrived at by Geitel in a paper published a few days previously (*Physikalische Zeitschrift*, 2 Jahrgang, No. 8, pp. 116–119). The leakage

was in each case attributed to the continuous production of ions throughout the volume of the air. In the present paper a description is given of the apparatus used in Mr. Wilson's experiments, and of further results obtained with it. The air, in most of the experiments, was contained in a glass bulb, coated internally with a layer of silver sufficiently thin to enable the position of a gold leaf within the vessel to be read by means of a microscope. The gold leaf was attached to a narrow brass strip, fixed by means of a sulphur bead to a brass rod passing through the neck of the bulb. The brass strip and gold leaf formed the whole of the system of which the fall of potential was observed; the capacity was thus very small. To avoid all danger of being misled by leakage through the insulating support, the rod, to which the leaking system was attached by the sulphur bead, was kept at constant potential by means of a condenser of zinc plates embedded in sulphur. By a momentary contact, brought about with the aid of a magnet, the initial potential of the leaking system was made equal to that of the supporting rod. The rate of leakage in air at atmospheric pressure corresponds to the production of about twenty ions of either sign in each c.c. per second; the ionisation is approximately proportional to the pressure. Experiments made with a portable apparatus showed that the ionisation in a closed vessel is the same when the experiment is performed in an underground tunnel as above ground. It appears, therefore, not to be due to the action of ionising radiation which has traversed our atmosphere.

"The Chemistry of Nerve-degeneration." By Dr. F. W. Mott, F.R.S., and Dr. W. D. Halliburton, F.R.S.

Linnean Society, March 21.—Mr. F. D. Godman, F.R.S., vice-president, in the chair.—Mr. J. E. Harting exhibited and made remarks on some photographs of female roedeer (*Capreolus caprea*) bearing antlers, one of which had been shot at Neudau, in East Styria, in December last.—Mr. H. J. Elwes, F.R.S., considered the case so remarkable and unusual as to suggest the probability of some mistake having been made in determining the sex. Mr. Harting, in reply, stated that this was by no means unique. In Germany, where roedeer are much more plentiful than in this country, several does with antlers had been recorded. Dr. Altum, in his *Forstzoologie* (Bd. i. p. 211), states that many such cases were known to him. One instance noted in the Black Forest at Kippenheim is mentioned in *The Zoologist*, 1866, p. 435. In that case the horns were "in the velvet," but perfectly hard; one was about 6 in. long with a single short tine, the other about 3 in. without any tine. A female roe with budding horns was shot in October 1875 by Mr. Duncan Davidson, of Inchmarlo, Banchory, Aberdeenshire. The skull of another in the museum of the Royal College of Surgeons, forwarded from Petworth Park, Sussex, by Lord Egremont, is figured in the *Proceedings of the Zoological Society*, 1879, p. 297. Mr. Harting also pointed out that such cases were not confined to the genus Capreolus, but had been noted rarely in *Cervus elaphus*, and once in the case of the American white-tailed deer *Cariacus virginianus* (shot in East Kootenay, British Columbia), a photograph of which he exhibited.—Mr. P. Chalmers Mitchell read a paper entitled "The Anatomy and Morphology of the Intestinal Tract in Birds; with Remarks on the Nomenclature and Valuation of Zoological Characters." He described the various conformations of the intestinal tract in birds, his material consisting of many hundreds of specimens belonging to all the living Ratitæ as well as all the orders and suborders and nearly all the families of Carinatæ. He discussed the morphology of the tract, distinguishing, in their adult anatomy and in their relation to the embryonic metamerism, the duodenum, Meckel's tract, and the rectum. He described the nature and distribution of the changes in these organs and in Meckel's diverticulum, and the colic cæca, and gave an account of a remarkable and hitherto undescribed series of nervous structures belonging to the autonomic nervous system apparently peculiar to birds. In discussing the relation of the series of facts described to the systems of avian classification, he insisted on the primary necessity of valuing characters as archicentric or apocentric, primitive or specialised. A common possession of a character in either the archicentric or apocentric condition was no indication of systematic affinity. Amongst apocentric characters he distinguished between *multi-radial apocentricities* (many of which were plastic effects and afforded no guide to affinity) and *uniradial apocentricities* which had arisen by a limitation and definition of variability in a particular branch of the family tree.

Geological Society, March 20.—J. J. H. Teall, V.P.R.S., president, in the chair. Prof. Friedrich Johann Becke, of Vienna, was proposed as a foreign correspondent of the Society.—Mr. H. B. Woodward called attention to a polished slab of landscape marble, or cotham stone, from the Rhætic Beds near Bristol, which had been lent for exhibition by Mr. Frederick James, curator of Maidstone Museum. The specimen showed that after the arborescent markings had been produced in the soft mud, some irregular and partial solidification took place in the upper layers of the deposit; and then during contraction a kind of subsidence occurred of the upper and harder portions into the lower and softer materials. This subsidence was accompanied by a breaking-up of the harder portions, suggesting a comparison (in miniature) with "broken beds" and even crush-conglomerates. The specimen was of considerable interest, as illustrating the mechanical changes produced during solidification. The following communications were read:—On a remarkable volcanic vent of Tertiary age in the Island of Arran, enclosing Mesozoic fossiliferous rocks (communicated by permission of the Director-General of H.M. Geological Survey). Part i. On the geological structure, by Benjamin Neeve Peach and William Gunn. The rocks which form the subject of this paper cover an area of about seven or eight square miles, and culminate in Ard Bheinn A'Chruach and Beinn Bhreac. They are in contact with formations ranging from the Lower Old Red Sandstone to the Trias, and are later in date even than the important faults of the area. They are made up partly of fragmental volcanic materials, and partly of various intrusive masses, confined within an almost unbroken ring of intrusive rocks. In addition to igneous fragments the clastic volcanic rocks contain fragments derived from the surrounding formations; and also masses of shale, marl, limestone and sandstone belonging to formations not now found *in situ* in the island. One of these is several acres in extent, contains fossils, and is in part of Rhætic age; a second is a fragment of Lias; and a third is of limestone and chert resembling the Antrim Cretaceous rocks, and yielding fossils. The absence of Oolitic and older Cretaceous seems to indicate a resemblance between a former succession in Arran and that now seen in Antrim.—Part ii. "Palæontological Notes, by E. T. Newton, F.R.S. The masses of Rhætic strata yield *Avicula contorto*, *Pecten valoniensis*, *Schizodus* (*Axinus*) *cloacinus*, etc.; those of Lower Lias *Gryphæa arcuata*, *Ammonites angulatus*, and new species of *Nuculana* and *Tancredia*, which are figured and described. Thin slices of the Cretaceous limestones prove to be very like those of the Antrim chalk, and the rocks yield determinable foraminifera, *Inocerami*, sponges, and echinoderms.—On the character of the Upper Coal Measures of North Staffordshire, Denbighshire, South Staffordshire and Nottinghamshire; and their relation to the productive series, by Walcot Gibson (communicated by permission of the Director of H.M. Geological Survey). The Upper Coal Measures of North Staffordshire are capable of a fourfold subdivision, the groups representing a definite sequence of red and grey strata.

MANCHESTER.

Literary and Philosophical Society, March 19.—Charles Bailey, vice-president, in the chair.—Mr. E. F. Morris exhibited two drawings of recent excavations in the Roman Forum. The one represented a rostrum, stated to be that from which Antony delivered his famous speech. It is built of tufa and concrete, and consists of five little vaulted rooms, as seen in the well-known medal of Palikanus. The other was a sketch of a little ædicula in brick work, the front decorated with two marble columns supporting an architrave on which is carved the name of the deity (Juturna) to which it was consecrated. In front of it is a circular well with an elegant marble head, ornamented with a carved cornice bearing an inscription stating that the well was consecrated to Juturna by Marcus Barbatius Pollio. Before the well is a marble altar with a sculptured front, on which are the figures of Mars and of a female deity—Juno or Venus. Signor Boni has also brought to light the celebrated fountain of Juturna, which is enclosed by a spacious rectangular construction in tufa-work of the Republican epoch. The water now gushes out fresh and clear, in abundance. The sculptures in the room enclosing the spring were also described.—Mr. Thomas Thorp showed photographs of the spectrum of the new star in Perseus, showing the bright lines very clearly. Mr. Thorp also described a variation in the ordinary arrangement of a star spectroscope, in which the eye-piece of the telescope used is replaced by a

doublet, one of the elements of which is a long focus lens which can be tilted and by that means made to yield a band of light in place of the line, an effect ordinarily secured by means of a cylindrical lens, as in Maclean's method.—The macro-lepidoptera of Sherwood Forest, by J. R. Hardy. The paper contained a list of 269 species collected in the course of the past twenty-two years, mostly in the district between Worksop, Edwinstowe and Chekerhouse. All the species, some of which are peculiar to the district, have been deposited in the Manchester Museum.

PARIS.

Academy of Sciences, April 1.—M. Fouqué in the chair.—A general proposition in the calculus of probabilities, by M. A. Liapounoff.—On the deformation of the general paraboloid, by M. Servant.—On the sum of the angles of a polygon with multiple connection, by M. M. d'Ocagne.—Studies in psycho-acoustics, by M. F. Larroque.—On the electro-capillary properties of some organic compounds in aqueous solution, by M. Gouy. If H is the maximum height of the column of the capillary electrometer with a given solution of a standard electrolyte, and H' the maximum height after the addition of an organic substance, then $1000\ (H-H')/H$ is a constant which varies with a constitution of the body and which varies with dilution in a characteristic manner. Preliminary measurements are given for a number of organic substances.—On some osmyl-oxalates, by M. L. Wintrebert. The osmyloxalates form a well characterised series of salts, details being given of the mode of preparation and properties of the salts of sodium, ammonium, silver, barium, strontium and calcium.—On the reducing properties of magnesium and aluminium, by M. A. Duboin.—On cinchonine, by MM. E. Jungfleisch and E. Léger. Ordinary commercial cinchonine always contains a variable quantity of hydrocinchonine, the separation of the latter being a somewhat tedious process. The physical constants of the purified cinchonine salts were determined and found to differ considerably from the accepted figures.—On some iodo-derivatives of phenol, by M. P. Brenans.—The action of the esters of dibasic acids upon the organometallic compounds, by M. Amand Valeur. The reaction of magnesium methyl iodide with the esters of oxalic, malonic and succinic acids was found to correspond with the action of the same reagent upon the esters of monobasic acids, except that with ethyl malonate an additional molecule of water is split off with the formation of an unsaturated alcohol.—On the organometallic compounds of magnesium, by MM. Tissier and Grignard. The principal product of the action of magnesium upon an alkyl iodide or bromide in ethereal solution is a compound of the type $C_nH_{2n+1}-Mg-I$, and this, on treatment with water, gives the hydrocarbon C_nH_{2n+2}. In the higher members of the series a secondary reaction takes place in which the hydrocarbon $C_nH_{2n+1}-C_nH_{2n+1}$ is formed. Thus secondary hexyl iodide gives hexane and dihexane.—Some new reactions of the organomagnesium compounds, by M. Ch. Moureu. Magnesium ethyl iodide reacts easily with amyl nitrite, giving diethyl-hydroxylamine. Nitroethane gives the same product, the reaction appearing to be a general one.—On the organomagnesium derivatives, by M. E. E. Blaise.—On a new synthesis of aniline, by M. George F. Jaubert. Benzene and hydroxylamine hydrochloride, heated with aluminium chloride, give traces of aniline.—On the mechanism of lipolytic reactions, by M. M. Hanriot.—On the internal organisation of *Pleurotomaria Beyrichii*, by MM. E. L. Bouvier and H. Fischer. Studies of the digestive tube and nervous system of this animal.—The sexual variation in the males of certain Coleoptera belonging to the family of the Bostrychides, by M. P. Lesne.—On the mode of production of eggs in *Trochus*, by M. A. Robert. The eggs of *Trochus conuloides* are produced in a long cylindrical string exactly resembling those of *Tr. granulatus*.—On the comparative value of saline and sugar solutions in experimental teratogenesis, by M. E. Bataillon.—On the origin of the paranuclei in the cells of the digestive gland of the crayfish, by M. P. Vigier.—Influence of the climatological conditions upon the growth of the shoots of the vine, by M. F. Kövessi.—The comparative study of the zoospore and the spermatozoid, by M. A. Dangeard.—New cytological researches on the Hymenomycetes, by M. René Maire.—On a conidian form of the fungus of black rot, by M. G. Delacroix.—The position and approximate velocity of a meteor, by M. Jean Mascart. A meteor which was seen in the neighbourhood of Angoulême on September 24, 1900, had a velocity of over 4 kilometres per second, and was entirely consumed at a height of about 40 kilometres.

NEW SOUTH WALES.

Royal Society, December 5, 1900.—Prof. Liversidge, F.R.S., president, in the chair.—Sir William Crookes, F.R.S., and Sir W. T. Thiselton-Dyer, K.C.M.G., F.R.S., were elected honorary members of the Society.—The following papers were read:—Intercolonial water rights as affected by federation, by H. G. McKinney.—The organisation, language, and initiation ceremonies of the aborigines of the south-east coast of New South Wales, by R. H. Mathews, and Miss M. M. Everitt.—This article described the laws of marriage, descent and relationship in force among the native tribes occupying the south-east coast of New South Wales from the Hawkesbury River to Cape Howe, on the Victorian frontier, and extending inland till met on the west by the Wiradjuri organisation. A grammar of the language of the Gundungurra, one of the principal tribes in the region dealt with, was also supplied, in which the structure of the native tongue was fully investigated and explained. The paper concluded with a short account of the Kudsha, or Narramang, a ceremony of initiation practised within the same geographical limits, by means of which the young men are admitted to the status and responsibilities of tribesmen.—Tables to facilitate the location of the cubic parabola, by C. J. Merfield. In some brief remarks the author gives an outline of the general application of the cubic parabola, when used as a transition to connect the straights and circular curves of railway lines. The paper forms a contribution to the engineering profession, and will be found useful to those engaged in the location of railway lines. A valuable table is appended, from which the constants of the curve for any case may be found. A complete numerical example illustrates the method of using the table.—Boogaldi meteorite, by Prof. Liversidge, F.R.S. This meteorite was exhibited by Mr. R. T. Baker at the June meeting of the Society, when he stated that it was found early in January 1900 at a place two miles from Boogaldi, a post town fifteen miles north-west of Coonanbarabran. Mr. Baker afterwards forwarded it to Prof. Liversidge for investigation and analysis. The meteorite is a metallic one or a siderite, and is somewhat pear-shaped; it is a little over five inches long by about three inches broad at the widest part, and it weighed before cutting 2057·5 grammes. Its sp. gr. at 14° C. was found to be 7·85. It was covered, as usual, with a closely adherent skin of fused oxides, except in one place where it had been detached, the exposed metal had a bright lustrous appearance like nickel iron. At the thick end of the meteorite the fused oxides forming the skin have been thrown into well-defined concentric waves or rings with transverse furrows in the direction of the thinner end of the meteorite—the waves and furrows gradually fade away in this direction. These waves and furrows are believed to show that the meteorite travelled through the earth's atmosphere with the thick end in front, the waves of fused oxide being thrown up by the resistance of the air, just as waves are formed in sand by the wind. That the meteorite did travel with the thick end first is confirmed by the fact that at the thin end there are longitudinal ridges and furrows in the fused skin which clearly show where the excess of fused oxide was dragged off; the luminous streak usually seen behind a meteorite is, if not wholly, certainly in part, due to the fused incandescence left in its trail. Hence the waves and other markings in the skin not only show the direction in which the meteorite travelled but also its position, *i.e.* with the curved point of the thin end downwards as represented in the photograph; for the fused oxides forming the skin are thickest on the lower side.—On a new aromatic aldehyde occurring in eucalyptus oils, by Henry G. Smith. In this paper the author records the results of his investigation (so far as he has gone) on the aldehyde occurring in so many eucalyptus oils, which had for a long time been supposed to be cuminaldehyde. The aldehyde occurs in greatest amount in the oils obtained from members of the group of Eucalypts known in Australia as the "Boxes." The true boxes, *E. hemiphloia*, *E. albens* and *E. Woollsiana*, contain it in the largest quantity. The oil was obtained from *E. hemiphloia*, this tree growing plentifully at Belmore, in the neighbourhood of Sydney. 1000 c.c. of the crude oil were distilled, and the constituents distilling below 190° C. removed, the remainder of the oil was agitated with acid sodium sulphite

with which it readily formed a solid compound, the pure aldehyde was easily obtained from this by the usual methods. The specific gravity of the aldehyde at 15° C. was ·9477. The specific rotation was $[\alpha]_D - 49·17°$, this somewhat high lævorotation causes those oils containing it to be lævorotatory, although mostly devoid of phellandrene. It is this aldehyde that causes the oil of *E. cnerifolia* of South Australia to be lævorotatory. The pure aldehyde has an aromatic odour and is slightly yellowish in tint. It was soluble in the usual solvents. The author proposes the name aromadendral for this aldehyde, and aromadendric acid for the corresponding acid.

St. Louis.

Academy of Science, March 18.—Prof. E. H. Keiser delivered an address showing the progress made in the science of chemistry during the nineteenth century.—Prof. F. E. Nipher exhibited pieces of pine board a foot square, showing the tracks of ball lightning discharges upon them like those formerly described by him in No. 6, vol. x. of the *Transactions* of the Academy. The discharges formerly described had been formed on a photographic film. The balls were very small, and wandered over the plate, leaving a track of metallic silver in their wake. In the present instance the balls were much larger, and they burned a deep channel in the wood. They are formed at the secondary spark gap of a coil. The terminals are pointed and are under control, so that the gap may be changed in length. To start the balls, the pointed terminals are put upon the wood surface, so near that the spark carbonises somewhat, after which the gap is made longer. These balls travel in either direction, when a direct current is used with a Wehnelt interrupter. This differs from the results reached on the photographic film with the Holtz machine. There the balls came from the kathode. Even when they originated at isolated points on the film, they travelled away from the kathode. In the present results, the balls have been caused to originate at isolated points, and two balls have started in opposite directions. Wood which gives little flame shows the phenomenon to best advantage, but the balls preserve their identity and travel slowly along even when completely surrounded by flames of the burning wood.

EGYPTIAN CHRONOLOGY.

A Self-verifying Chronological History of Ancient Egypt. A Book of Startling Discoveries. By Orlando P. Schmidt. Pp. 569. (Cincinnati: O. G. C. Shaw, 1900.)

THE portly volume before us professes to deal with the "chronological history" of Egypt, and to treat the subject in such a lucid manner that every part of it explains itself and "proves" itself. The author is candid, and advertises his work in the freest possible manner, and he appears to be thoroughly convinced of the supreme value of his labours. According to him, the field of Egyptian history was hastily explored, "usually at odd times"—whatever that may mean—but armed with his "key," which a "fortuitous discovery" had placed in his hands, he "entered a lost world, all recollection of which had died out, and there made a series of discoveries, and gathered together a great mass of new historical facts, the startling and far-reaching importance of which it would be almost impossible to estimate." He admits that he once held many of the opinions common to modern Egyptologists in general, but his "native common sense recoiled from" the errors and superstitions regarding the Egyptians which were current among so-called "scientists"; though of certain errors and superstitions he once found it impossible to free his mind, and apparently this is still the case. He wrote his book whilst "the researches were being made," and his "point of view was constantly changing," and his "horizon was constantly widening." Among Egyptologists, the author thinks "superficial skepticism" has taken the place of "scientific criticism," and this had led many of them "to belittle and misrepresent the civilisation of Egypt prior to the beginning of the Fourth Dynasty," and they tell us "flat footed" (whatever this word may mean here) "that the first three dynasties of Manetho were mythical." Mr. Schmidt thinks that the names of Noah, Shem, Ham and Japheth are Egyptian and not Hebrew words, and he says that "scientists" will have to account for the remarkable coincidence between the date of the Hyksos expulsion and that of Jacob's birth.

The merest glance at the book shows that Mr. Schmidt has built his book up entirely, in our opinion, from the works of Egyptologists, and yet he does not wish to "weaken the effect of the facts presented" by encumbering the text with a mass of miscellaneous citations from so-called "authorities," an ingenious way of avoiding the publication of his vast indebtedness. He is not content with setting Egyptian chronology on a firm base, but he wishes to take a prominent position as an exponent of the vexed Mycenæan question, for he tells us quite gravely that the "Ionians (*Ia-nim*) were settled in the Grecian Archipelago and on the adjoining shores of Greece and Asia Minor as far back as the reign of Teta, or 3146 B.C."! It has been necessary to select the above statements from Mr. Schmidt's preface so that the reader may know the manner and style of the book which he has to deal with; but before we attempt to summarise the general contents we must point out that the industrious author of this remarkable compilation seems to have been mistaken on certain important points. To begin with, all the evidence which has been derived from prehistoric sites in Egypt during the last six years proves conclusively that the first three dynasties are historical facts, and no competent Egyptologist ever doubted the existence of the kings who belonged to them. It is clear, from the remarks which Mr. Schmidt makes in his preface, that he does not know enough Egyptology to decide what authority to follow. Egyptologists have for a generation or more declared the great antiquity of Egyptian civilisation, and it is only the semi-religious and pseudo-scientific writers on Egyptian history who have been too biased to see the light; the writings of some of the latter must form the slain enemies whom Mr. Schmidt sets out to slay again. Had Mr. Schmidt read M. J. de Morgan's "Recherches Préhistoriques," which were published in 1896 and 1897, he would have seen that Egyptian civilisation must be thousands of years older than he supposes; and it is possible that he would have kept his work in manuscript. Sir Norman Lockyer has proclaimed, in his "Dawn of Astronomy," with no uncertain voice the great antiquity of Egyptian civilisation, and, what is more, his facts have never yet been controverted; but we see no mention of the results achieved by de Morgan and Lockyer, or even any indication that they are known to him in Mr. Schmidt's book. We have no wish to belittle the work of any pioneer in archæology, but when we see Mr. Schmidt solemnly quoting Canon Rawlinson's *old* publications on Egyptian chronology we feel sure that he does not know how to select his authorities; and if he refers to excellent and, according to their bias, honest men like Canon Rawlinson as "authorities," it proves conclusively that he does not know what an Egyptologist is.

Mr. Schmidt divides his book into two parts, which are preceded by a preface, from which we have already quoted, and by an introduction; in the first part, he deals with the Sothiac (*sic*) system of chronology and the lists of Manetho, the Twelve Months, the Signs of the Zodiac, the formation of the Solar System, the present state of Egyptian chronology, the Sothiac (*sic*) year, Manetho, the chronological numbers in Josephus, &c. In each of these sections he lays down the law in an arbitrary manner, and he incorporates in his paragraphs a number of remarks which appear to us as irrelevant. In the second part, he discusses one dynasty after the other, and accepts what suits his own views in the writings of ancient and modern authors, and rejects as worthless what he cannot explain in their works. We have read the book with some care, but have not yet found the "startling discoveries" which Mr. Schmidt professes to have made, and we have failed to see how his chronological history is "self-verifying." We are familiar with the Sothic year, and the manner in which it has been applied to the elucidation of Egyptian chronology; but as different investigators, though using the same data concerning the rising of Sothis, arrive at different results, we feel that its correct application is not in all cases sufficiently understood. No one doubts that the Egyptians were astronomers of no mean order, and in recent years Sir Norman Lockyer has shown us what an integral part of their religious system the knowledge required for orienting temples was; but more would be known of their astronomical knowledge if the astronomical texts could be fully

understood in these days, and it is impossible to assign correct meanings to them until we know the exact signification of every word which occurs in them.

The weak part of Mr. Schmidt's argument is that, even supposing all his statements about dates in the Sothic year were correct and could be proved, he does not allow a sufficient number of Sothic years to cover the long period of years in which the Egyptian civilisation was evolved, and developed, and matured, and decayed; and it seems to us absurd to limit this period to three Sothic years, or 4380 ordinary years. Mr. Schmidt's system of chronology is worth no more than any other in which a large amount of "playing at doing sums" occurs, and he has merely put together in book form a series of notes and extracts from the works of Egyptologists, and from those of writers like Bunsen and Cory, which he has arranged according to his own peculiar views; the result is a perfectly unreadable volume of 569 pages, in which the "omissions" of one ancient authority and the "mistakes" of another are paraded in a bewildering manner. We have no wish to be flippant or to treat Mr. Schmidt's book in other than a serious manner, but his conclusions remind us forcibly of the result of the investigations into the date of the building of the Tower of Babel of the eminent English divine who declared that the "last brick was laid on the top stage of the Tower of Babel at Borsippa at 4 p.m. on Thursday, April 15, B.C. 2247." We cannot possess a continuous and accurate chronology of Egypt until we know how many kings reigned between Mena and Nectanebus, and how many years each reigned, and who succeeded whom; to make such a chronology at present is impossible because the necessary data do not exist. The writer who assigns precise dates to certain events in Egyptian history, *e.g.* the date B.C. 4244 to "the establishment of the kingdom," probably deserves to be considered either a "crank" or a charlatan, and in any case the presumption of the writer who asserts definitely that the Ionians were settled on the shores of "Greece and Asia Minor as far back as the reign of Teta, or 3146 B.C." is stupendous.

We are not reassured on the matter of Mr. Schmidt's scholarship when we find such blunders and spellings as the following: Puon-et, p. 7, *uae* (there is no such word) p. 9, Hyk-sat-u, p. 13, Rokchoris, p. 14, Tarako, p. 14, Sothiac, p. 16 and *passim*, Sopdet, p. 17, Uon-nofer, p. 20, Ânu, p. 27, Ach-i-u, Ta-ān-nut, p. 30, Pa-api, p. 35, Amen-em-het, p. 49, Rohk-nez, p. 52, Num, p. 61, Usertasen, p. 81, Quebahu, p. 105, the identification of Ta-ânut (*sic*) with This, the derivation of the Hebrew name "Adam" from that of Mena, the first historical king of Egypt (!), p. 117, Hus-et and Hus-ir, p. 122, Per-son, p. 131, Osiropis, p. 253, Zawyet-el-Arrian, p. 268, Elephantinæn, *ibid.*; this list might be increased almost indefinitely. Mr. Schmidt looks upon the story of the Flood as an allegory which he interprets thus. Noah was born B.C. 2948, and the Flood "broke loose" over the land B.C. 2348; Thebes became independent B.C. 2948, and the XIth, XIIth and XIIIth dynasties of kings reigned exactly 600 years, *i.e.* a period equal to the age of Noah when the Flood "broke loose." According to Mr. Schmidt the Flood was no flood of water, but an invasion of Hyksos, and the ark to which Noah and his family, &c., fled was nothing else than the city of Thebes, because the Hebrew word for ark is *Têbhâh*, and this, according to Mr. Schmidt, is the name of the city called Thebes. The sending forth of the dove from the ark is another part of the allegory, and means that Noah and his sons sent forth from Thebes messengers to the Hyksos offering their submission, which was duly accepted, and payment of tribute imposed upon them!

From reasoning of this kind the reader will easily be able to gauge Mr. Schmidt's qualifications as a reformer of the chronology of Egypt; as a final proof of the correctness of his views on this subject he points triumphantly to the fact that the fifteen cubits of height above the mountains which the waters reached at the time of the Flood refers to the depth of the waters of the annual Nile inundation, which he declares to be exactly fifteen cubits at Heliopolis! When he deals with Babylonian questions Mr. Schmidt is equally unfortunate, for on p. 545 he gravely refers to the discovery of a tablet "recording the war waged by Khammurabi against Eri-aku and his Elamite allies"; a reformer of Mr. Schmidt's pretensions should at least have shown that he had read that this "discovery" was exploded finally by Mr. L. W. King in the first volume of his "Letters of Khammurabi," published in 1898, for, as now stated by Mr. Schmidt, his arguments fall to the ground. Before he writes another book of "startling discoveries" we hope he will read the current literature of the subject, and will remember that assertion is not evidence, and that theories and hypotheses are not proofs.

ELECTRO-CHEMISTRY.

Practical Electro-Chemistry. By G. Bertram Blount. Pp xi+374. (Westminster: A. Constable and Co., Ltd., 1901.) Price 15*s.* net.

ALTHOUGH the foundation on which electro-chemistry is built was to a large extent laid by the genius and splendid research work of two Englishmen, Davy and Faraday, and is practically based on the laws enunciated by the latter, yet to-day, when many branches of industrial chemistry are being revolutionised by the introduction of this branch of chemical science, we as a nation know practically nothing about it. In America we are confronted by numerous works upon the subject; if we turn to Germany, there again we find a whole library of books devoted entirely to electro-chemical science and to its industrial application. Turning to our own country, what do we see? One or two books on electro-plating, books on electrical engineering, and a few *translations* of German works on electro-chemical analysis.

It was, therefore, with sincere pleasure and eager anticipation that one saw, in the publishers' announcements at the end of last year, that Messrs. Constable and Co. would shortly bring out a work on "Practical Electro-Chemistry," by Mr. Bertram Blount. The book which is now published consists of eight sections devoted to different branches of electro-chemistry.

The first, or introductory, section treats in an interesting manner of electrolysis and more or less of the theory of solution. A useful subsection is also given on the "Method of calculating output in electrolytic processes." After discussing at no very great length a particular

case, viz. that of the electrolysis of fused sodium chloride, Mr. Blount says:

"Thus in practice he who is firmly grounded in these primary principles can deal with each particular case as it arises, not experimenting blindly, but with certain definite and exact generalisations to guide him."

This is very true, but the example taken is one in which the course of reaction is very readily followed out, and although we presume Mr. Blount does not profess to deal exhaustively with this phase of the subject, yet the section would have been much more instructive if Mr. Blount had also included an example where the main reactions are masked by secondary changes.

The next section deals with "Winning and refining of metals by electrolytic means in aqueous solutions." To the winning and refining of copper as being "the largest of all electrolytic industries" is assigned the chief place. The author has failed to treat this part of the subject with sufficient breadth. There are two main methods for obtaining copper electrolytically—the multiple system, in which the anodes and kathodes are suspended opposite to each other, and the series or Hayden system, in which at one end of the vat there is an anode plate, at the other end a kathode plate, the intervening space being occupied with plates of the same quality as the anode plate. These plates function both as anode and kathode, the surface opposite the anode acting as kathode, that opposite the kathode as anode. Mr. Blount has dealt fairly fully with the multiple system, but only very shortly with the Hayden system, which he condemns, hardly, however, giving sufficient evidence for his condemnation. Surely, also, a little more space might profitably have been devoted to the treatment of the anode sludge, the successful working up of which often goes a long way towards making an electrolytic process a paying one.

On p. 125, with reference to the difficulties met with in obtaining nickel in a state of purity, the author gives this useful warning:

"The study of the degree of purification effected by the electrolytic refining of nickel is particularly instructive, and should suffice to dispose of, once for all, the ridiculous belief that a metal prepared by electrolysis is necessarily and *ipso facto* of unusual purity."

The author is hardly correct in saying that no serious attempt appears to have been made to refine tin electrolytically. He is evidently unaware that a patent has been taken out by Mr. Claus for refining impure tin. In Mr. Claus's process, tin cast into plates is made the anode in a bath of sodium sulphide, the kathode being of tinned iron. The impurities, as well as gold and silver, remain in the anode sludge, and tin is deposited in a very high state of purity at the kathode.

Probably the third section, which treats of the electrolysis of fused salts, will be of most interest to the general reader, seeing that under this head the production of aluminium is naturally dealt with. The short section on the electric furnace, carbides and the researches of Moissan, which follows, will repay perusal, if only by pointing out the vast fields of research which the introduction of electricity to chemical processes has opened up.

Section vi., which is assigned to alkali, chlorine and their products, is extremely disappointing. This branch is, perhaps, one of the most important in the whole range of electro-chemistry, and should therefore have been treated comprehensively. The production of chlorine and caustic soda by electrolysis of common salt receives somewhat exhaustive treatment. But the important, much-worked-at and widely-debated subject of hypochlorites and chlorates, together with the practical and theoretical causes which underlie these processes, are handled most inadequately. The casual reader would carry away the impression that if a cold solution of a chloride is electrolysed without a diaphragm, a solution of a hypochlorite will be produced, but that on electrolysing at high temperatures a chlorate will be obtained. Unfortunately, the electrolysis of a chloride is by no means so simple. There is a very large amount of literature on the subject, and if Mr. Blount had endeavoured to summarise the various methods and the theories advanced, this section would have been very valuable, but he has unfortunately failed to do this.

The part devoted to electrolysis of organic compounds is short, and therefore it would be rash to expect too much from it.

The book as a whole is eminently readable, but it is doubtful whether it will be of much value to the manufacturer or practical chemist. But, in fairness to the author, let us not forget that it is extremely difficult to obtain trustworthy and authentic information of manufacturing processes; the main facts may be published, but it is often the seemingly unimportant details which make or mar a process. The value of the work to the scientific reader would have been greatly enhanced if the author had given references to the original literature from which he obtained his information. To general chemical students the book, although not entirely up to date, may be recommended, in that it deals with the newest of chemical industries in an interesting manner, and will perhaps induce some of the younger chemists to engage in this important branch of study.

F. MOLLWO PERKIN.

SCLATER'S MAMMALS OF SOUTH AFRICA.

The Mammals of South Africa. By W. L. Sclater. Vol. ii. Pp. xii+241. Illustrated. (London: Porter, 1901.)

THE first volume of this important work having been already reviewed in these columns, and its main scope and style referred to, our notice of the second and concluding volume may be comparatively brief, especially as it is chiefly devoted to the smaller mammals, such as rodents, bats and insectivora, which command a much smaller sphere of general interest than is the case with their larger terrestrial relatives.

In describing the rodents and bats, the author has been confronted with a task of considerable difficulty on account of having access to the types of many species only during short and busy visits to England. Consequently a considerable portion of this section of the work partakes in some degree of the nature of a compilation; and Mr. Sclater himself would probably be among the first to admit that some amount of revision will have to take place in the future with regard

to certain species and genera. When, however, these great difficulties are taken into account, it must be allowed that the author has fulfilled his task in a highly creditable and satisfactory manner.

And as regards nomenclature, classification and the splitting-up of certain old, unwieldy generic groups like the squirrels into divisions of smaller size, Mr. Sclater is well abreast of modern ideas. One of the most noticeable of these modern changes in classification is the transference of the so-called Cape jumping-hare—the spring-haas of the Boers, from its old association with the jerboas—to a position near the cane-rat and the porcupines. Nor is this all that is noteworthy in Mr. Sclater's remarks on the creature; for we are told that, in spite of the huge bounds it takes, "it is never very rapid in its movements, and can be easily overtaken." This information we have not found given in any of the other works to which we have turned. It is a matter for regret that the portrait of the spring-haas, like many of the other figures in the book, has not been executed in a more satisfactory style.

An old error—to wit, that it burrows—in connection with the cane-rat is also corrected, mainly on the evidence of the late Prof. Peters and Captain Drummond.

Among the most curious and interesting of all the smaller mammals of South Africa are the elephant-shrews, or jumping shrews, and the golden moles, and of each of these Mr. Sclater gives an excellent account, both as regards bodily characteristics and habits, although further observations are stated to be required with regard to the mode of life of the last-mentioned animal.

"The golden mole," writes the author, "is exceedingly common in gardens, where it makes runs in all directions in search of the worms and grubs on which it lives. Although generally supposed to be destructive, it is really a great aid to the gardener, as it destroys quantities of larvæ, especially those of a certain gamma moth. . . . A certain amount of mischief, however, is done by the mole in pursuit of its prey by disturbance of roots and freshly-sewn seeds."

In addition to the Rodentia, Chiroptera and Insectivora, the present volume also includes the South African Cetacea and Edentata. Among the cetaceans special interest attaches to the author's description of a specimen of the lesser sperm-whale recently taken in Table Bay, as the external characters of this rare whale have been hitherto very imperfectly known. Of the specimen in question Mr. Sclater gives a sketch, which shows the characteristic shark-like mouth and small dorsal fin. Certain differences in size which have been thought to indicate specific distinction are, in the author's opinion, probably due to difference of sex in the individuals which have from time to time been examined.

The aard-vark and the pangolin Mr. Sclater, although with some hesitation, still retains in the same order with the typical South American Edentata. And it must be confessed that certain observations which have recently been made with regard to the myology of these creatures tends, so far as it goes, to justify this conservatism. Whether there really is any close relationship between the two groups is a question of the very highest importance in regard to certain views that have been recently expressed in favour of a former connection between Africa and South America. And it would greatly help matters if a decisive answer could be given on this point.

Mr. Sclater may be congratulated on the completion of a very important and valuable work. R. L.

INFINITESIMAL GEOMETRY.

Einführung in die Theorie der Curven in der Ebene und im Raume. By Dr. Georg Scheffers. Pp. viii + 360. (Leipzig: Veit and Co., 1901.) M. 10.

THIS volume is the first of two which will make a complete work under the title "Anwendung der Differential- und Integral-Rechnung auf Geometrie." The subject-matter of the two volumes may be said to be, roughly, the infinitesimal geometry of curves and surfaces respectively. The first volume is divided into three sections, dealing with plane curves, curves in space, and developable surfaces. The first section does not attempt to be a complete exposition of the subject, and must be regarded as an introduction to what follows, intended to accustom readers who are already well grounded in differential and integral calculus to the style and methods which are employed later. The theory of the curvature of plane curves is based on the definition of contact of an assigned order, which is explained with great exactness. The differential invariants of a curve for the group of movements in the plane are fully investigated, and their properties established in an elementary manner without introducing notions of groups or partial differential equations. Envelopes, evolutes, singular points, and the geometrical significance of differential equations of the first order and degree are discussed shortly. In connection with the trajectories of a family of curves, the problem is completely solved of finding all curves for which the product of the normal and radius of curvature is constant. The remainder of the first section is devoted to an explanation of curvilinear coordinates.

The second section contains a thorough and systematic account of the curvature, torsion, and allied theory of curves in space. The dual interpretation of an orthogonal substitution of coordinates as a change of frame of reference and as a movement in space is first carefully explained, and the theory of the intrinsic properties of curves is built upon it. Particularly interesting are the discussions of the differential invariants and of the integration of the intrinsic equations of a curve, in the course of which an elementary account of Riccati's equation is given. Conditions for contact of an assigned order are carefully laid down, and from them the relations between a curve and its osculating circle and helices are deduced; in particular we have the interesting result that the axes of all osculating helices at any point generate a cylindroid.

In the third section the main properties of the surface generated by the tangents to a curve are established. The general ruled surface is introduced in order to provide a rigorous investigation of what is meant by saying that consecutive generators intersect. The remainder of the section is occupied with various loci connected with a given curve, such as evolutes, involutes, parallel curves, polar surface, rectifying surface, etc. The text ends with a short account of minimal lines and minimal curves.

Few points in this book call for adverse criticism. In determining the motion of the frame consisting of tangent, normal and binormal at any point of a curve, it would be clearer to introduce the curvature and torsion into the general formulæ for moving axes as measures of small rotations, and it would be more convenient to make a positive torsion correspond to a positive rotation (in this connection the English reader may be warned that the term "rechts-gewunden" is applied to what we should call a "left-handed" screw). It is surprising that no general method is given for expanding the coordinates in powers of the arc; the employment of these expansions very much simplifies the investigation of osculating helices and of the osculating cone, and can hardly be objected to on the ground of being a "Kunstgriff."

The book is written in a very pleasing style, with that light and clear touch which we are accustomed to associate with French writers, and except in one or two instances the analysis is very judiciously handled. For soundness it leaves nothing to be desired and its incompleteness is only an incentive to deeper research into the subject. Specially commendable are the careful explanations of points which are usually slurred over. A distinct feature is the introduction of imaginary quantities at an early stage and the discussion of exceptional cases that arise in connection with minimal lines and curves. The whole book is pervaded by the ideas which are associated with the name of the author's great master, Sophus Lie.

The type is clear and good, misprints seldom occur, and the figures are excellent. The practice of giving two or three orthogonal projections instead of one figure in perspective is much to be commended as a means of conveying exact information and of training the student to build up a mental conception of a figure in three dimensions.

The second volume, which is promised in the course of next year, will be awaited with the greatest interest.

R. W. H. T. H.

OUR BOOK SHELF.

Les Phénomènes electriques et leurs Applications. By H. Vivarez. Pp. vi + 574. (Paris: Carré and Naud, 1901.) Price Fr. 15.

M. VIVAREZ'S book covers almost the whole field of modern electrical practice in a manner which is neither too technical nor too popular. The daily increasing applications of electricity in the industries and arts render such a book valuable in two ways. In the first place, it should appeal to the ordinary engineer, manufacturer or man of science who finds himself obliged to make use of electricity in some way or other, and who can turn to its pages for general information on the subject. Secondly, the electrical engineer is generally obliged nowadays to become a specialist in some particular branch of his profession, and is liable, in consequence, to get out of touch with other branches with which it is desirable he should have a general, if not a detailed, acquaintance. Such he can obtain from a book of this kind. M. Vivarez has set out with the object of supplying the wants of these persons, and also, doubtless, the want of the intelligent amateur who is anxious to keep pace with modern industrial progress, and he has, we think, succeeded admirably in his endeavour. He has produced a book which is thoroughly readable and interesting, and is not at all overladen with calculation or technical detail. Perhaps in some cases he has shown rather a tendency to skip over the less interesting parts at a sacrifice of clearness, as, for example, in the section on units. This may not be of much importance to the electrician who will have obtained his fundamental conceptions elsewhere, but it is a great disadvantage to the non-electrical reader, who can never properly understand the subject unless his knowledge of the groundwork be sound—a truth he is himself too prone to ignore.

In a book of this kind a great deal depends on the proper proportioning of the space allotted to the various subjects considered. On the whole, M. Vivarez has divided his space very fairly, though he has given rather an undue preponderance to the more modern "engineering" developments. More space should, we think, have been devoted to telegraphy, which is at once the oldest and the most important application of electricity; electrochemistry and metallurgy are also treated somewhat too briefly. We looked in vain, also, for any description of vacuum tubes; their omission is unfortunate, seeing of what value they have become to mankind since Röntgen's discovery. The X-ray may have passed rather from the hands of the electrician to those of the surgeon, but it remains, all the same, an important "phénomène électrique."

The most interesting portions of the book, to our mind, are the historical parts. M. Vivarez has given a brief historical account of all the important developments, and has carried this to the extent of even giving a short history of the industrial employment of coal. These historical summaries are both interesting and valuable, the more so as this is a side of science too frequently neglected. Is it because the development is so rapid that the history cannot keep pace with it, or, as we are inclined to believe, because of the natural antipathy of the average engineer to anything that tends to be literary? In any case, there can be no doubt that many engineers will be found ignorant, not only of the works, but even of the names of the men who have made their profession, and for this reason we would recommend the book before us to the student of electrical engineering; it will show him the importance of the work of the man of science, and may bear useful fruit in inducing him to read original papers.

The Agricultural Changes and Laying Down Land to Grass. By R. H. Elliott, 2nd edition. Pp. xii + 101. (Kelso: J. and J. H. Rutherford, 1901.)

MR. ELLIOTT has for some years been pursuing a system of agriculture on his estate in Roxburgh, the essential feature of which is that he secures a thick turf by the use of heavy seedlings of the stronger grasses and other pasture plants, and after half a dozen years or so humus has accumulated to such an extent that the land may be put through a course of tillage cultivation without the use of any fertiliser but artificial manures. The seed-mixture that he uses is characterised not only by its abundance, but also by the fact that it contains the seeds of such out-of-the-way plants as burnet and chicory. Mr. Elliott is a firm believer in the ameliorative influence of deep roots on the subsoil, and certainly his pastures yield a large amount of food. He claims that the temporary leys secured under his system are much more profitable than "our two great enemies, turnips and cereals," and our national statistics show that many farmers are of the same opinion. The system has, no doubt, answered well in the comparatively cool and humid atmosphere of the Cheviot uplands, but whether it is capable of successful adoption in the drier dristricts of England is another matter. As Mr. Elliott has not put his system into competition with the ordinary methods of management of temporary grass land, it is impossible to say whether it is an improvement on general practice or not. Be this as it may, it does not

seem that the author has made out a case for the Board of Agriculture taking over his farm and converting it into a national object-lesson. It would be much cheaper, and quite as useful, to have his prescriptions tested on a practical scale in other parts of the country, and this the Board of Agriculture and the agricultural colleges might very well arrange to do.

Friederich Wöhler, Ein Jugendbildniss in Briefen an Hermann von Meyer. Edited by Georg W. A. Kahlbaum. Pp. 97. (Leipzig: J. A. Barth, 1900.) Price M. 2.40.

THESE letters were found amongst the Hermann von Meyer's bequest to the Munich Academy of Science, and Prof. Kahlbaum has done well by making them accessible to a larger circle in their present form.

Although A. W. v. Hofmann, in his charming work, "Zur Erinnerung an Vorangegangene Freunde" (Braunschweig: Vieweg und Sohn, 1888), has given a history of Wöhler's life, these letters to the intimate friend of his youth furnish a most interesting supplement to Hofmann's narrative, and will be particularly appreciated by the surviving pupils and friends who enjoyed the privilege of personal acquaintance with Wöhler, or the still larger number who now or in the future take an interest in the history of the early days of modern chemistry. This publication comprises letters covering but a short period, they are neither remarkable for style nor form, as they were obviously only intended for the person to whom they were addressed; but they are, perhaps, all the more valuable an this account, for they give a characteristic and life-like record. Prof. Kahlbaum, whilst scrupulously preserving the original text of the letters, has taken great pains in collecting additional information respecting the persons and places mentioned, and his copious footnotes afford a most useful framework to the letters, which in themselves give us so vivid a picture of the condition of things under which the ardent and youthful enthusiast pursued, with such eager devotion, his experiments and studies, and thus prepared himself for the high position he so soon attained amongst the leading chemists of his age. H. M.

Die Flora der Deutschen Schutz-gebiete in der Südsee. Von. Prof. Dr. Karl Schumann und Dr. Karl Lauterbach. Pp. xvi + 613, with 23 lithographic plates. Large octavo. (Leipzig: Gebr. Borntraeger, 1901.)

SINCE the acquisition of Kaiser Wilhelmsland and the neighbouring islands, German explorers and botanists have been busy working out the flora of their new possessions; and now, some seventeen years from the date of annexation, all available information is made accessible in the imposing volume under review. The immediate cause of the issue of this Flora is that the series of extensive collections that have recently come to hand necessitated a considerable volume for their adequate description. This, and the fact that the literature on the flora is much scattered, has prompted the authors to expand their undertaking so as to include the results of earlier explorations. The area dealt with includes, besides Kaiser Wilhelmsland (German New Guinea), the adjacent Bismarck Archipelago, the more westerly of the Solomon Islands, the Marshall, Caroline and Marianne Islands. In all over 2200 species are enumerated, and of these 400 are described for the first time, or have become known only from the recent collections which have led to the publication of this Flora. The species are distributed as follows:—Algæ, 222; Fungi and Lichens, 226; Bryophytes, 200; Pteridophytes, 155; Gymnosperms, 12; Monocotyledons, 392; Dicotyledons, 1000. The new forms are all fully described, whilst both for these and for all the plants enumerated, admirably full localities are given. Many of the new forms are of considerable interest, and fourteen new genera are created. There is a new species of *Cycas* occurring in the Bismarck Gebirge up to a height of 3000 ft., in habit resembling an Australian *Xanthorrhœa;* Guppy's interesting *Sararanga* (Pandanaceæ) is recorded with an extended distribution; there is a small Palm, *Dammera*, allied to *Licuala;* whilst among Dicotyledons, *Ficus arbuscula*, a fig-tree 3 to 6 feet high, may be mentioned. The new *Hibiscus papuanus* is spoken of as possessing the most strikingly beautiful flowers in the whole region. The additions to Rubiaceæ are considerable, and include *Dolicholobium Gertrudis* with curious dimorphic flowers. A second species of *Bothryocline* (Compositæ) considerably extends the distribution of a genus previously restricted to Africa. In *Psychotria myrmecophila*, from the Bismarck Gebirge, we have a new type of ant-plant with curious excavated trifid stipules, which appear to harbour ants in their recesses; its biological relations will require to be worked out on the spot.

The work contains, in addition to a brief introduction by Prof. Schumann, an interesting history of the botanical exploration of the whole region by Dr. Lauterbach, the enlightened director of the New Guinea Company. Included in the volume are twenty-three large plates, which adequately portray the characters of the more important novelties. Certainly the authors are to be congratulated upon their achievement, which is a model of what such a work should be. It will prove a boon to the local officials, colonists and missionaries, and cannot help but stimulate further research.

Fact and Fable in Psychology. By Joseph Jastrow. Pp. xi + 375. (Boston and New York: Houghton, Mifflin and Co., 1900.)

OF the eleven essays here reprinted the first seven are devoted to a common subject, viz. the so-called "occult" side of mental life and its significance for psychology. Prof. Jastrow's attitude towards the whole problem is marked by a luminous common sense which is, unfortunately, rarer even among serious psychologists than it should be. For scientific psychology the real question, as he never tires of pointing out, is not how to explain the marvels of spiritualism and allied arts, but how to account for the existence and wide diffusion of the state of mind which can believe in them. It is for the expert in conjuring tricks to show how the feats of the medium and the miracle-worker are done; the task of the psychologist is to investigate the "Psychology of Deception." Incidentally, however, such papers as Prof. Jastrow's essays on "The Psychology of Spiritualism" and "Hypnotism and its Antecedents," besides throwing light on the mental condition of the deceived, are interesting as showing how more than one famous occultist has executed his deceptions. The latter of the two papers just named brings out clearly and well the enormous difference between the spirit and methods of science and of superstition in dealing with one and the same set of facts. In the essay on "The Problems of Psychical Research" Prof. Jastrow is perhaps on more debatable ground, though his attitude seems to the present reviewer at least the only scientific one. Briefly his position may be summed up thus: the psychologist, as such, has no interest in the facts of "telepathy" except in so far as they throw light, as any facts about abnormal mental states may, on the known laws of normal mental processes. The "psychical researcher," on the other hand, thinks his facts sufficient warrant for postulating types of mental process of which normal life reveals nothing. Hence, unlike the psychologist, he approaches the facts in a non-scientific spirit. In a subsequent "Study of Involuntary Movements," conclusive experimental proof is given of the dependence of "thought-reading" performances upon unconscious movements of the muscles of the "subject" towards the object on which attention is directed. Of the remaining papers the most suggestive is perhaps that on "The Dreams of the Blind."

LETTER TO THE EDITOR.

The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*]

Selenium in Sulphuric Acid.

WITH reference to the article in NATURE on the beer poisoning epidemic (pp. 541–542) as to the possibility of the presence of selenium, either conjointly with or preferentially to some compound of arsenic producing the calamity, the following observations may be of interest.

Some few years ago, in the course of an investigation on the inertness of the alkaline earths towards hydrochloric acid gas (*Ber. Deutsch. Chem. Ges.* xxix. 577–580), I had occasion to use sulphuric acid (labelled *puriss*) as a dehydrating agent for the gas, but after passage of the gas for some time a red deposit of selenium was invariably observed at the bottom of the Drechsel wash-bottle containing the acid.

It would, of course, be impossible now to trace the past history of such samples of acid, which might have come from several manufacturers, but these observations may show that selenium is a far more common impurity even in the best samples of acid than hitherto supposed.

Though some of the ill-informed writers and politicians of to-day might be invited, as a form of hard labour, to obtain sulphuric or any other acid in a state of purity (*credite experto*), yet it is not apparent that this acid need be used for the preparation of invert sugar to be subsequently applied to the manufacture of beer.

V. H. VELEY.

Oxford, April 6.

THE BOARD OF TRADE AND ELECTRIC LIGHTING.

THE Board of Trade has been busily engaged during the past few weeks with two inquiries of great importance to the electric lighting industry. The decision arrived at in the one of these which dealt with the maximum price to be charged for electric energy has already been referred to in our issue of March 14 (p. 474). The other inquiry, which was opened on March 1 under the presidency of Sir Courtenay Boyle, occupied the attention of the Board of Trade for six days, and has raised some points of considerable technical and scientific interest. The Board has not, as yet, given its decision, but the hearing of evidence and the pleadings have been completed, and we propose briefly to review the expert evidence in the following article.

The object of the inquiry was to consider an application to the Board of Trade, made by various electric lighting companies and local authorities, notably by the Westminster Electric Supply Corporation, for an alteration in one of the Board of Trade regulations. The regulation in question provided that "no change should be made in the pressure of the supply to any premises . . . except with the consent of the consumer." This regulation, it will be seen, gives to the consumer the absolute power to veto any change in the standard pressure of the supply to his premises, a change, for example, from 100 volts to 200 volts, which the supply company may desire to make. It was this power of veto that the companies wished to remove, and accordingly they made application for an alteration of the regulation by which for the words "with the consent of the consumer" should be substituted the words "on such terms and conditions as may be agreed upon between the undertakers and consumer, or, failing agreement, as may be settled by an arbitrator appointed by the Board of Trade," or words to that effect.

The difficulties which have led to this inquiry have all arisen out of the change from a 100-volt to a 200-volt supply which is being made by the Westminster and other electric light supply companies. The change was started in the case of the Westminster Corporation, which we may take as a typical instance, in 1896, and their reasons for making it were as follows. The system, as originally laid down, was a three wire system with 100 volts between each outer conductor and the middle; by 1895 the demand for electric light had increased so much that the street mains were beginning to get overloaded, that is to say, the current which they were obliged to carry was more than was economically good. The evil of this overloading was shown in two ways: on account of the heavy current which the mains were carrying the loss of energy in them, which is proportional to the square of the current, was very great, amounting, in fact, to about 12½ per cent. of the total output; also the drop of voltage in the mains was considerable and made it increasingly difficult to maintain the voltage at the consumer's terminals within the limits of variation allowed by the Board of Trade. In these circumstances, the supply company was faced with a difficulty which could be overcome only in two ways. Either they could put down fresh mains year by year to meet the increasing demand, a proceeding which would involve an expenditure of something like 7500*l*. a year, or they could supply the same amount of energy, using a smaller current and a higher voltage. If the voltage were doubled the same amount of energy would be supplied by only half the current, and the energy loss in the mains would be only one-quarter of its former amount; the drop of voltage would at the same time be halved (the percentage drop being therefore only one-quarter of its former value), and thus the second difficulty referred to above would be avoided. It is perfectly evident, therefore, that from the supply company's point of view the best course to adopt was to increase the standard voltage of the supply. And indirectly, also, this course must be beneficial to the consumers, and prospective consumers, for anything that tends to cheapen the cost of supply to the company tends also to lower the price the consumer has to pay for the energy he uses.

The consumer has, however, another way in which he can look at the question. It is not simply energy that he wishes to buy, but energy that can be economically converted into light; in fact, he really wants simply to purchase light. If, therefore, the 200-volt lamp is less efficient than the 100-volt lamp, it may be to his disadvantage to have to use energy at 200 volts, even though the cost of such energy may be less. For example, if we may state a similar case, it is not an advantage to a consumer to be obliged to drink arsenical beer, although the cost may be less than that of pure beer. In addition, the change necessitates, in most cases, refitting and rewiring of the premises, since the fittings that are suitable for 100 volts, especially if they are of old patterns, are not good enough for 200 volts, and also the wiring is often not good enough for the higher pressure. The question of the liability of the supply company for the costs of these alterations and for the inconvenience caused by the necessity of making them is, however, one which can reasonably be settled by arbitration. The matter of prime importance to the consumer is, we consider, the question of the inferiority—real or alleged—of the light obtained with 200-volt lamps.

Before the Westminster Corporation decided to make the change, they ascertained to their own satisfaction that the 200-volt lamps were as good as the 100-volt, or, if not as good, so little inferior that the disadvantage was more than counterbalanced by the lowering of the price charged to the consumer. This is a point, however, on which doctors disagree, as was shown by the expert

evidence at the inquiry, and it is interesting to note the grounds given for the various opinions held.

Prof. Kennedy, who is adviser to the Westminster Corporation, advanced the argument that if the 200-volt lamp were really less efficient than the 100-volt, then the consumption of energy per lamp connected to the mains should have steadily increased since 1897, as more and more consumers were changed over to the higher pressure. But this argument is, as Prof. Ayrton pointed out, quite fallacious; if the consumer is supplied with a 200-volt so-called 8 c.p. lamp, which is, in reality (as in an actual case quoted by Prof. Ayrton), only giving a candle-power of 1·8 and is consuming 15·3 watts per candle, it will only consume 28 watts; the consumption of energy is therefore rather less than with a 100-volt 8 c.p. lamp giving its correct candle-power and consuming 4 watts per candle. The consumption of energy per lamp in cases like this goes down, from which Prof. Kennedy would argue that the efficiency has gone up; whereas, as a matter of fact, it has diminished enormously, the effect appearing, not in an increased bill, but in a decrease of light. As a matter of fact, this is the way in which the inefficient lamps show their badness; they do not maintain their correct candle-power and take more watts, but they fall off in candle-power for the same consumption of energy. This was exemplified in the evidence given by Mr. B. M. Drake. Most engineers and lamp-makers call the watts consumed per candle by the lamp its efficiency, though, as a matter of fact, this quantity is a measure of the inefficiency. Mr. Drake prefers to measure the inefficiency by the complaints received per customer, and there can be no doubt that, though unscientific, this is a very good way of getting at an average value. According to this standard, Mr. Drake finds that the 200-volt lamp is much inferior to the 100-volt.

There was not wanting evidence in favour of the 200-volt lamp, but the majority of the experts, certainly in the cases in which the results of actual tests were given, were against it. To take one other instance, Mr. Gunyon, on behalf of the London County Council, gave evidence to the effect that the 200-volt lamp cost more, lasted for fewer hours, and was less efficient than the 100-volt; he gave the results of tests on four different makes of 200-volt lamps, the average consumption of energy in the *new* lamps coming out at 5·4, 4·1, 5·8 and 5·6 watts per candle respectively, the good value (4·1) being for a foreign make of lamps. These figures show that lamp-makers have by no means yet got over the difficulties of the manufacture of the 200-volt lamp which were pointed out by Mr. Byng in a paper read before the Institution of Electrical Engineers three years ago (*Journal* of the Institution of Electrical Engineers, 1898, vol. xxvii. p. 118). That they will ultimately triumph over the difficulties all must hope; that they have satisfactorily done so now cannot, we think, be maintained.

The inferiority of the high-voltage lamp is, however, as we have pointed out, not the only consideration; the change is, without doubt, beneficial to the supply company, and it must, moreover, be remembered that in many cases the change has been all but completely carried out. The Westminster Corporation have only some half a dozen consumers who are still being supplied at the low pressure; the remainder, either through choice, through indifference, or through ignorance of their power to refuse, have submitted to the change. No doubt these few outstanding consumers are an annoyance to the company and a source, possibly, of loss, although the company have raised the price they are charging them to the maximum allowable; yet we cannot help sympathising with the consumer who objects to being compelled to use what he honestly, and with justice, believes to be a worse article.

SEISMOLOGY IN JAPAN.

THE chief interest attached to the publications mentioned below[1] is the fact that while giving us an insight into the attitude taken by the Government of Japan in regard to seismology, they form an important link in the history of the modern development of that subject.

On February 22, 1880, a rather severe earthquake so far excited the curiosity of the inhabitants of Tokyo and Yokohama that, with the object of studying such tremblings, a Seismological Society was founded. This society existed for twelve years and published twenty volumes. The usefulness of its work, attracting the attention of the Japanese Government, led to the establishment of a chair of seismology at the Imperial University, and the organising of a bureau which now controls nearly 1000 observing stations. The next great stimulus that seismology received came from the terrible disaster of October 28, 1891. Ten thousand persons were killed, more than fifteen thousand were wounded, and thirty million dollars' worth of property were destroyed. A comparison of the buildings which remained standing with those which were shattered and those which were utterly ruined indicated that something might be done to minimise such disasters, and to accomplish this, by virtue of an Imperial Ordinance, on June 25, 1892, an Earthquake Investigation Committee was established. This body consists of some twenty-eight members selected from amongst the best-known engineers, architects and men of science in Japan. Two well-known names—Prof. D. Kikuchi and Dr. F. Ōmori—appear as president and secretary. The *modus vivendi*, which can be seen in the Parliamentary Budget, seems to have an annual variation of from 1000*l*. to 5000*l*. Amongst the various investigations which this committee proposed to undertake we find the following:—

To collect documents relating to seismology and volcanology; to draw up a statistical account of seismic phenomena in Japan, such, for example, as might be required by insurance companies whose risks extend to disasters caused by earthquakes; to conduct geological researches bearing upon seismology; to extend our knowledge respecting the nature of earthquake motion; to determine the velocities with which earthquakes are propagated from point to point; to make observations on changes in the vertical and earth "pulsations"; to compare the movements resulting from given earthquakes as recorded on the surface of the earth and at depths which are comparable with the depths to which foundations of buildings may be carried; to extend observations on the variability of magnetic elements, there being reasons to believe that these may hold a certain relationship to seismic activities; to observe changes in temperature at great depths; to determine strength constants for building materials produced in Japan; to measure accelerations and maximum velocities necessary for the shattering, overturning or projection of various bodies, amongst which no less than sixteen types of model houses are specified; to erect buildings specially designed to resist earthquakes; to study the effects of earthquakes on modern construction; and generally the committee undertook to make any investigation which may ultimately result in reducing the loss of life and property which so frequently accompanies violent earthquakes.

Although only nine years have elapsed since this elaborate programme was formulated, every item in it has received serious attention.

From volumes iii. and iv. we see that Profs. Tanabe and Mano have worked at the strength constants of

[1] Publications of the Earthquake Investigation Committee in Foreign Languages. No. 3, pp. 103; No. 4, pp. 141; No. 5, pp. 82; and No. 6, pp. 181. (Tokyo, 1900–1901.)

building materials, and investigated the effects of several earthquakes upon tall chimneys. Dr. B. Koto has handed to the committee twenty-two papers on geological subjects connected with seismology and volcanology. Dr. H. Nagaoka gives a paper of intense interest to all physicists on the determination of the elastic constants of rocks; whilst the well-known professor of seismology, Dr. F. Ōmori, contributes six papers, each of importance to seismologists, and for the most part indispensable to those who have to construct in earthquake countries.

Volumes v. and vi., which contain the analysis of the diagrams of 246 earthquakes observed in Tokyo between July 1898 and December 1899, are entirely from Dr. Ōmori's pen, and although we may not concur in all the results he sets before us, seismologists in general must thank him for the vast quantity of material which he has brought together and systematised for their consideration. For the earthquakes which originated at great distances from Japan, so far as possible each seismogram has been divided into parts which succeed each other in the following order: "First preliminary tremors," in which waves of 4 seconds period are superimposed upon those of 8 seconds; "second preliminary tremors," with periods of 8 seconds, and accompanied by undulations of 14, 25 and 66 seconds period; "the principal portion" of the earthquake, which is divided into three phases also dependent on period, and finally the "end portion," in which period is fairly regular. The regularity of the terminal vibrations may, as Dr. Ōmori remarks, be explained on the assumption that different portions of the earth's crust have particular periods of free oscillation. The discussion of these various types of earthquake motion is based on the assumption that the waves recorded are *horizontal movements and not tiltings of the ground.*

One observation which led Dr. Ōmori to take this view is that he has obtained seismograms which show that the amplitude of motion depends upon the multiplication ratio of the writing pointers attached to his pendulums, and not upon their sensibility to tilting. In addition to this he points out that if the undulations recorded were due to tilting, then the accelerations involved are such that our sense of feeling should be affected, which is not the case. Since Dr. A. Cancani, in 1893, drew attention to the fact that calculations based on a knowledge of the period, velocity and maximum tiltings of these unfelt undulations led to the conclusion that the inhabitants of the world were raised and lowered two or three feet hundreds of times per annum and had never observed the same, seismologists have regarded with suspicion the elements in the calculations leading to these results. Notwithstanding this, when we have so very much evidence of turbulent wave-like motion in and around epifocal districts, and evidence of repeated tiltings at distances of several hundred miles from the same, it is difficult to escape from the conclusion that similar but slower period movements may be propagated, like a swell upon an ocean, to very distant places, and seismographic pendulums be caused to swing.

Dr. Ōmori has certainly thrown new light upon the nature of the large waves, and it does not seem improbable that investigations carried out upon other lines may, if not completely at least partially, confirm his views.

A more debatable subject touched upon relates to paths followed by earthquake waves through the earth's crust. Because the velocity of the quick period phase of the large waves nearly equals that of local earthquakes, it is assumed that the former, like the latter, are propagated along the surface of the earth's crust, whilst waves which precede them travel at some small depth in the same. Inasmuch as the first preliminary tremors have, at a given station, a duration proportional to the arcual distance of this station from the origin of the earthquake, Dr. Ōmori thinks it likely that they are transmitted along paths nearly parallel to the surface of the earth, and at a probably constant depth.

Several sections in vol. v. refer to subjects which are not seismic, although they are of great interest to those engaged in certain branches of physical research. For example, references are made to the effect of slight loads upon masonry structures, whilst "oscillations of the ground," whose origin is not seismic, are discussed at some length. That we have for years past been acquainted with movements of pendulums and balances not proper to those of the instruments themselves, which may continue for hours or days, suggests the question whether we are not here being re-introduced to an old enemy in a new dress. Are these movements due to those of the ground or to local movements in the atmosphere? Can Dr. Ōmori assure us that similar instruments, placed in different rooms or under conditions which are different with regard to temperature and ventilation, behave similarly? If this be the case, then the distinction which has so frequently been drawn between "pulsations" and "air tremors" will be more clearly established. In a stable at Shide "air tremor" effects are, at certain seasons, frequent, whilst at times pendulums with a 15 seconds period will yield diagrams showing that they have been moving regularly with a period of two or three minutes. In an adjoining coach-house these movements are absent, and similar phenomena are common to Tokyo and other places.

What has here been said indicates the nature of the work now in progress in Dai Nippon, a complete account of which is to be found in thirty-two well-illustrated quarto volumes, which, unfortunately for Europeans, are written in Chinese characters. These volumes are with but little doubt one of the greatest store-houses extant of information relating to practical seismology, and as such it is to be hoped that an abstract, or at least a table, of their contents may be published in a European language.

As an example of their value we may select vols. xxii. and xxv., referring to an earthquake which in 1897 devastated North-Eastern India, and cost British investors and taxpayers several millions sterling. The first of these is by Dr. T. Nakamura, an architect, and it contrasts those forms of structure which withstood the effects of the earthquake with those which failed. The second, which treats of railway and bridge construction, is by Mr. T. Koyama, a railway engineer. These gentlemen are two out of four who were sent to India by their Government for the purpose of increasing their own extensive knowledge as to forms of structures most suitable for earthquake countries. On this occasion, as in others, special men were selected for special work, with the result that, not only has Japan profited by disasters of this character, but she has become a teacher of nations in practical seismology, and we, amongst others, may offer her thanks and congratulations on her efforts to save life and property.

J. Milne.

THE EYE IN THE RECENTLY DISCOVERED CAVE SALAMANDER OF TEXAS.[1]

The tailed Batrachia have during recent years attained an increased importance zoologically, by appreciation of the fact that in respect to many features in which their living representatives present a simplification of organisation they are retrograde. While but one of them possesses a complete maxillo-jugal arch, none are pentadactyle in both fore- and hind-limbs; and the unexpected has been reached, in the discovery that there

[1] "The Eyes of the Blind Vertebrates of North America," by C. H. Eigenmann (*Trans.* Americ. Microsc. Soc., vol. xxi. pp. 49-60), by C. H. Eigenmann and W. A. Denny (*Biological Bulletin*, Boston, U.S.A., vol. ii. pp. 33-40)

are no fewer than ten species of six genera which are lungless, and that in some of these respiration is largely buccal or pharyngeal, and may even, in all probability, involve the tips of the toes, as in *Autodax* and species of other known genera.

Conspicuous among recently discovered species are three of American origin which are cave-dwellers. Of these, one (a *Spelerpes*), occurring in the Mississippi Vale, has nondegenerate eyes; another (*Typhlotriton*), more restricted in the same region, has eyes which during growth undergo a recognisable degeneration. The third (*Typhlomolge*), discovered in 1896 in the underground waters of Texas, where it was obtained from an artesian well, said by our authors to be now thrown up at the rate of about fifty a year, is quite blind, possessed of functionless eyes. It is with the paper upon this genus that we have chiefly here to deal. The animal itself is of especial interest, as furnishing the much-desired American counterpart for the European *Proteus* long known. It differs from this, however, in being shorter bodied and longer limbed—so much so that the limbs appear by attenuation to have become converted into tactile organs—and the discovery that the eye is destitute of lens, rods and cones, and eye-muscles (which is the most interesting fact announced in these papers) is thus intensely significant, as it presents us among the Batrachia with a condition recalling that of the famous blind locust of the New Zealand caves, in which, under the functional atrophy of the eye, the antennæ have similarly become elongated and more important.

The second paper deals with the eye of the Mississippi cave salamander *Typhlotriton*, which, while "detecting its food by the sense of touch," shows only the first stages of that degeneration of the eye and its associated organs occurring in the Typhlomolge type. Both papers are illustrated, though very poorly, and they do not in this respect compare with previously published works on other blind animals which might be cited. Moreover, there is in the first paper an inexplicable error, for the senior author, stating that "the eye of Typhlotriton will be dealt with in another place" (*i.e.* the second paper herein quoted), continues erroneously to use this generic name in describing the Typhlomolge eye.

Typhlomolge is in every respect a most remarkable creature, as examination of the example preserved in our National Museum at South Kensington will show. The description of its eye, coming to us at a time when there has just been found (in the French Congo area) a frog in which the terminal phalanges of four of the hinder digits, perforating the overlying integument as do the ribs of the long-known Pleurodile Newt, project, freely and exposed, as sharply recurved claws. All this brings forcibly before us the lesson that in morphologically specialised forms of life, such as we are too apt to pooh-pooh, there are to be found facts which, on the whole, are among the most trustworthy, in enabling us to gauge the limits of nature's operations. Truly has Weismann remarked (as pointed out by the senior author in his 1899 Woods' Holl Lecture on "The Blind Fishes") that "an investigation into the history of degenerate forms often teaches us more of the causes of change in organic nature than can be learned by the study of the progressive ones."

G. B. H.

THE COMMERCIAL USES OF PEAT.

THE difficulty in obtaining coal for industrial purposes, and the high price that has had to be paid for it recently, especially where works are situated at long distances away from the mines, has led to more attention being paid to the use of peat for fuel. In the "Notes" of May 31, 1900 (vol. lxii. p. 108), a short description was given of the uses to which peat was being applied in Austria in the manufacture of textile fabrics. In a recent number of the *Engineer* (February 8, 1901) an account was also given of the peat fuel industry in Sweden. It is said that there is hardly any question of the day so prominent in that country as the use of peat fuel as a substitute for coal. The Government, recognising the importance of this matter, has appointed a Crown Peat Engineer, at a salary of 500*l*. a year, to survey the principal Crown peat bogs and to report upon the quality and suitability of the peat for use as fuel in locomotive engines. At several of the large works in Sweden peat is now used for generating steam. At the great Yungtell Metal Works and the Motala Shipbuilding Works, it is also used in generating furnace gases, the fuel being prepared by specially constructed works. At the former establishment, engines of 230 horse-power are supplied with steam generated by this fuel. In the province of Smaland a syndicate has recently purchased the peat bogs, from which it is estimated that a million tons of fuel will be produced in a year. At the Karpalund sugar refinery peat is now solely used for the nine boilers in use there of 100 horse-power each; the fuel being first converted into gas in generators in front of the boilers. This establishment has purchased an adjacent bog containing sufficient peat to supply the works for twenty years. The bog is connected with the factory by a Decauville railway. The furnaces were formerly fed by coal obtained from England, and a very great saving has been effected, the peat fuel costing less than half that of coal. On several of the railways peat is being tried as fuel for the locomotives with every promise of permanent success. There are several different kinds of machines for making this fuel. The process something resembles brick-making. The turf is cut from the bog either by manual labour or machinery, and stacked in summer to be air-dried, any remaining moisture being removed in heated drums or by centrifugals, and the peat is then compressed into briquettes. It is claimed that one ton of dried peat from the best class of bogs is equal to half a ton of English coal.

The largest area of peat in England is to be found in the Fen district, where it covers 600 square miles and the depth varies from 2 to 10 feet in thickness, and at Whittlesea Mere as much as 18 feet. Nearly the whole of the peat in the Fenland has been drained and is now cultivated.[1] In a few places in the Fens it is sun-dried and used for fuel. In the form of powder and mixed with carbolic acid it is also extensively used as a deodorant for earth closets and similar purposes, works for this purpose being established in Cambridgeshire.

There are also large deposits in the East Riding of Yorkshire along the valleys of the Trent and Ouse, Hatfield Chase covering 12,000 acres, where a manufactory has been for some years in existence for drying and preparing the peat for litter for stables and cow-houses. Its antiseptic properties make this litter very valuable, especially in large towns where straw is difficult to obtain. There are also large areas of peat in other parts of the country, as at Chatmoss in Lancashire and on Dartmoor.

In Ireland, the peat bogs cover about 5000 square miles, or about one-seventh of the whole country; some of the bogs are 43 feet deep, the average thickness being 26 feet. Occasionally, owing to an excess of water, the peat overflows the basin in which it is contained and flows over the cultivated land. Thus a few years ago the bog near Tullamore overflowed and covered nearly three square miles of land. Sun-dried peat is used in Ireland to a considerable extent for fuel. Some attempt has been made to work it for commercial purposes. The Irish Amelioration Society some years ago encouraged the conversion of it into charcoal, but the process was

[1] "The History of the Fens of South Lincolnshire." (London: Chapman and Hall.)

not found to pay commercially, although peat charcoal is well adapted for working and tempering iron for the finer kinds of cutlery. The Irish Peat Company erected extensive plant for drying and distilling the peat and producing tar, illuminating oil and paraffin. At these works, one ton of peat yielded 10 gallons of tar, or 28 lbs. of illuminating oil and 1 lb. of paraffin.

One of the last volumes of the Encyclopédie Scientifique, published in Paris,[1] is devoted to a treatise on peat and peat bogs. It describes the conditions under which peat was originally formed, the plants of which it is composed, the chemical analysis of its constituents, the principal bogs in Europe, the age of peat as deduced from the remains of animals, flint implements and tools found buried in it, the methods of obtaining and preparing peat for commercial purposes, the uses to which it is applied and its calorific value and antiseptic qualities.

W. H. WHEELER.

THE BRITISH AND GERMAN ANTARCTIC SHIPS.

THE two great Antarctic expeditions have made a stride towards completeness by the launch at Dundee and Kiel of the exploring ships *Discovery* and *Gauss*, both vessels built, at great expense, specially for service in the Antarctic ice. No complete official announcement of the organisation and programme of either expedition has yet been made. However, the two ships are afloat, and appear to be the finest vessels for ice-navigation ever constructed, not even excepting the *Fram*, which of course was planned for drifting with the ice-floes, not for sailing through them.

The following table compares the chief dimensions of the two vessels, so far as we have been able to ascertain them :—

	Discovery.	*Gauss.*
Length over all ... ... (feet) ...	—	168
,, at water line ... ,, ..	172	—
,, between perpendiculars ,, ...	—	151
Extreme Breadth ... ... ,, ...	34	35
Probable displacement fully loaded (tons)	1750	1450
Horse-power	450	300–500
Rig	Barque	Barquentine
Complement all told (souls)	46	28

It is stated the name of *Gauss* was given to the German vessel by the Emperor to emphasise the scientific character of her mission by associating it with the memory of the great authority on terrestrial magnetism.

The German vessel, although a little smaller than the *Discovery*, is intended to carry so much smaller a crew that she will probably prove to be no more crowded with her stores and equipment. Both vessels are strongly built of oak and sheathed in greenheart. The *Discovery*, like the *Fram*, has her frames in contact throughout her whole length, and the joints caulked so that even if all her triple skin of planking were stripped from her the vessel would still be watertight and seaworthy. She is of whaler pattern to the extent that her sides are not pierced by any openings, the only daylight for the cabins coming from deck-lights ; but the cabins, though dark and uninviting at the launch, are exceptionally roomy and well-planned, and when lighted by the electric light will be extremely comfortable. The *Gauss* is also to be furnished with the vital necessity of electric light, a boon that none but polar voyagers can fully appreciate, and she is, in addition, to have the luxury of steam-pipes for heating purposes throughout the whole inhabited part of the ship ; the *Discovery* will probably be heated by stoves.

Both vessels are provided with wells and gear for hoisting out both rudder and propeller, and a spare rudder will be carried which can be shipped securely and speedily if the original steering gear should be seriously damaged. The bows of both ships are heavily plated with steel to enable them to cut through or break comparatively thin ice ; but the form of the stem is different. Both have a great sheer, so that the vessel would tend to ride up on any floating ice she encountered and break it with her weight, but the stem of the British ship is a straight line forming an obtuse angle with the keel, while that of the German vessel is a convex curve. The sterns also differ, that of the British vessel having a much longer overhanging counter than the *Gauss*, so that her length over all is probably from 15 to 20 feet greater.

The details of laboratory accommodation can be more profitably described when the space is finally apportioned and the equipment in place ; but the magnetic observatory on the *Discovery* has been very carefully planned so that it shall be more than 30 feet from any iron or steel —even the bolts and nails in its vicinity are all of brass.

The living rooms in both vessels are amidships, the stokehold and engine-room being placed right aft, while the whole lower hold is utilised as a great coal-bunker along the length of the ship. The *Discovery* is rigged as a barque ; the rig of the *Gauss* is officially described as that of a "three masted schooner," but her published sail-plan shows the foremast completely square-rigged, the main and mizzen having only fore-and-aft sails, so that she is better called a barquentine. We believe that this rig, rendered necessary probably on account of the small crew carried, is not a usual one for polar ships. Machinery and masts are now being rapidly put in place, and the *Discovery* may be expected in the Thames to take her stores on board about the end of May or early in June.

MEETING OF THE INTERNATIONAL ASSOCIATION OF ACADEMIES.

THE business of the Paris meeting of the International Association of Academies was commenced on Tuesday morning, when the delegates assembled at the Institute. The delegates were received, on Saturday, by the president ; and the French Government, as well as the Municipal Authorities, have combined with the Institute to make the meeting a success by facilitating all the arrangements and providing lavish entertainment. By this official action, the dignity and importance of the meeting are declared, and the delegates are made to feel that they are welcome visitors.

Tuesday's meeting was devoted to preparatory business, and M. Darboux gave an address on the objects and work of the Association. The financial position was considered, and suggested additions and alterations of the rules were discussed. A committee was appointed to consider a scheme for the mutual loan of manuscripts. In the evening, the president of the Institute, Count de Franqueville, gave a reception to the delegates and their families at his residence, the Château de la Muette. Yesterday the arrangements included a visit to the Château of Chantilly, bequeathed to the Institute by the Duc d'Aumale. This afternoon there will be a reception by M. Émile Faguet at the French Academy, and in the evening a dinner will be given by the Institute. On Saturday afternoon a visit will be made to the National Library, under the direction of M. Léopold Delisle, and on Saturday evening the Municipal Council will give a dinner to the delegates and members of the Institute. The dinner will be followed by a reception and concert, to which the families of the guests are invited. On Sunday a special piece will be represented at the Comédie-Française in honour of the delegates.

From this programme it will be seen that the serious

[1] "La Tourbe et Les Tourbiéres, par Alb Larbalétrier. Encyclopédie cientifique des Aide Memoire." (Paris : Masson et Cie.)

work of the meeting will be relieved by congenial entertainment. The way in which the various authorities, as well as private individuals, are contributing to make matters run smoothly, and to ensure that the delegates shall remember their visit with pleasure, is a noteworthy characteristic of the arrangements.

NOTES.

IT appears that the Bement collection of minerals, which became the property of the American Museum of Natural History at the end of last year, was presented to the museum by Mr. J. Pierpont Morgan. The collection is estimated to be worth about 40,000*l.*, and was commenced by Mr. C. S. Bement, of Philadelphia, who began it thirty-five years ago and kept adding to it until it passed from his possession. Neither time nor money was spared in gathering desirable specimens, and in 1884 the Bement collection was looked upon as so important as to be made the subject of a special report in the interest of the National Museum, Washington. Mr. Morgan's public spirit and generosity have prevented the collection from being distributed or from leaving the United States. In addition to this gift, he has presented to the museum the Tiffany collection of gems. Mr. Morgan's earlier contributions to the museum, of which he is a trustee, have been on a munificent scale, but the recent gifts surpass previous ones in value and scientific interest. Referring to the gifts at a recent meeting of the Board of Trustees, Mr. A. S. Hewitt remarked :—"The trustees rejoice that the museum begins the new century with the acquisition of two very remarkable, if not unique, collections of minerals, which, added to the treasures already in its possession, raise its position among the museums of the world to the level occupied by the British Museum, heretofore, by common consent, regarded as rich beyond comparison in rare specimens.

WITH reference to the recent proposal to stock the London parks with butterflies, Prof. Meldola writes to say that the experiment, although worth trying, is not, in his opinion, likely to prove successful. The species which have been observed in the Metropolis are, with the exception, perhaps, of *Pieris rapae*, only casual visitors, for the most part imported and only occasionally immigrating spontaneously. It is very doubtful whether the species which it is proposed to introduce, viz. the *Vanessas*, would survive more than the first season, and if any should escape the London sparrow and hibernate it is more than probable that they would voluntarily migrate the following spring to fresher surroundings than could be offered by a vegetation which had gone through the ordeal of a London winter. Prof. Meldola adds that in the year 1871 he perfectly well remembers the leopard-moth, *Zeuzera aesculi*, being quite common on the tree-trunks in the London parks and squares. It was observed during that season that the ground at the foot of the trees was often littered with wings of the moth, as though some bird—probably the sparrow—had been at work among the insects. If the suggestion to stock the parks necessitated an annual renewal of the butterflies, it would be better to leave them in their native country haunts.

IT is stated that the Cunard Company contemplate utilising the Marconi wireless telegraph on their Atlantic steamers.

MR. C. E. BORCHGREVINK, the Antarctic explorer, has been created a Knight of the Order of St. Olaf by King Oscar.

MR. J. WILSON, U.S. Secretary of Agriculture, has arranged to carry into effect, on July 1, the reorganisation of certain of the divisions of the Department of Agriculture, as provided by the last Congress. It may be remembered that, in addition to the Weather Bureau and the Bureau of Animal Industry, four new bureaus were created, namely, those of Plant Industry, of Forestry, of Chemistry and of Soils.

WE learn from *Science* that an influential committee has been formed in Italy to celebrate the fortieth anniversary of Prof. Paul Mantegazza's entrance on his career as a teacher. This event will be celebrated at Florence on April 30, and at the same time as the thirtieth anniversary of the Italian Society of Anthropology. It is proposed to collect a sum of money to be used for the endowment of the new laboratory of anthropometry which Prof. Mantegazza has established at Florence.

THE Rome correspondent of the *Times* records the opening, by Lord Currie, of the British Archæological School in Rome. More than one hundred representatives of international archæology gathered at the Palazzo Odescalchi, where the school is situated, the Italian Government being represented by Commendatore Fiorilli, Director-General of Antiquities and Fine Arts, the Academia dei Lincei by several members, the German Archæological Institute by Profs. Petersen and Hülsen, and the French École de Rome by Mgr. Duchesne.

SEVERAL papers on scientific aspects of alcoholism were read at the International Temperance Congress held at Vienna last week. Among the subjects described and discussed were the effect of small fixed quantities of alcohol on the speed and quality of certain simple and calculable mental operations, such as sums in addition, and committing figures to memory ; the poisonous effects of alcohol in certain nervous affections ; the effect upon the power of resistance to disease ; remedial measures ; and reforms recently introduced into the French Army for the repression of alcoholism.

IT has been decided (says the *Victorian Naturalist*) that the National Fund raised in memory of the late Baron von Mueller, Government Botanist of Victoria, shall be devoted to the institution of a medal and prize to be awarded at intervals of not less than two years to the author of the most important contribution to natural knowledge which shall have been published in the British dominions not more than five years, or less than one year, prior to the date of the award, preference being given to work having special reference to Australasia. It is proposed that the Mueller Medal shall be awarded by a committee of the Australasian Association for the Advancement of Science appointed for the purpose every two years.

FROM the *Victorian Naturalist* we understand that Prof. Spencer, F.R.S., of the Melbourne University, and Mr. F. J. Gillen, of South Australia, will start from Oodnadatta, the present terminus of the transcontinental railway, nearly 700 miles north of Adelaide, on their expedition for the purpose of studying the habits and customs of the aboriginals of the northern portion of Central Australia, about the middle of the present month. The start has been somewhat delayed owing to the drought which has existed for some time in the portion of the continent to be visited. It is also proposed to cross into Queensland and continue Dr. Roth's ethnological work, and afterwards to traverse some of the larger rivers of the Northern Territory, and if time permit, to visit the Wyndham district on Cambridge Gulf in North-West Australia.

A COMMITTEE, to be known as the Lightning Research Committee, has been organised by the Royal Institute of British Architects and the Surveyors' Institution, with the object of collecting and tabulating information from all parts of the country as to damage resulting to buildings from lightning. The committee includes Mr. John Slater (chairman), Major-General E. R. Festing, C.B., F.R.S., Dr. Oliver Lodge, F.R.S., Messrs. J. Gavey, W. P. Goulding, W. N. Shaw, F.R.S., H. H. Statham, A. R. Stenning, Arthur Vernon, Killingworth Hedges, C.E. (hon. secretary). In pursuance of their inquiry the committee seek the co-operation of competent observers in all parts of the country, with a view to obtaining accurate

details, noted on the spot, of the effect of lightning-strokes on buildings, whether fitted with conductors or not. Persons willing to assist by their observations are invited to communicate with the secretary at the offices of the Royal Institute of British Architects, 9 Conduit Street, London, W.

WE learn from the *British Medical Journal* that in the course of the present year a statue of Pasteur is to be erected in the town of Dôle, in the Jura Department, which was his birthplace. The statue, which is from the chisel of M. Antonin Carlès, is in bronze, and stands on a conical pedestal 8 metres high. Pasteur is represented as standing in an attitude of meditation. At the base of the monument is a group representing Humanity holding out two children to Pasteur, whilst Science offers him a palm.

THE death is announced in the *Times*, at the age of ninety-three years, of Prof. Paul Chaix, a well-known citizen of Geneva and a geographer of distinction. In 1836 he was appointed master of geography and history in the Industrial College of Geneva, and in 1868 he became professor at the Gymnasium, and a few years later at the University. M. Chaix was an active member of the German Geographical Society, and an honorary corresponding member of the Royal Geographical Society. He was the author of a map of Savoy, a history of Central America, various elementary geographical works, and papers to geographical and other journals.

THE Paris correspondent of the *Chemist and Druggist* announces the death, at Grenoble, of Prof. F. M. Raoult, an eminent chemist and senior of the Faculty of Sciences of that town. He was a corresponding member of the Paris Academy of Sciences, a foreign member of the Chemical Society, London, and of the Imperial Academy of St. Petersburg, and a Commander of the Legion of Honour. M. Raoult was 71 years of age, and held a high place amongst French chemists. The death is also announced of M. Maxime Cornu, a well-known French botanist, who took a leading part in the endeavours to eradicate phylloxera in France. The deceased was a professor at the Paris Museum of Natural History, and contributed largely to the literature of botany.

IT is a matter for congratulation that serious efforts are being made by the municipal authorities in many civilised countries to combat disease by all means available for that purpose. We therefore welcome the news that an excellent institution for the exclusive treatment of patients suffering from the various forms of cancer—either curable or incurable—is being built in Moscow at the expense, which is said to be an enormous one, of the municipality of that city. It is understood, however, that the main object of erecting this special hospital is to provide the necessary means of studying the nature of cancer from every possible point of view and of enabling and encouraging more thorough pathological and clinical research to be carried out in connection with that malady. Accordingly, we may reasonably hope that by carefully conducted scientific investigations the light of knowledge will be thrown upon a scourge which has, of late years, and particularly in the northern regions of the Russian Empire, assumed a most formidable extent and character. It may be added that the new institute will be under the entire management of a committee consisting of several members of the medical faculty, with Dr. Lewschin, professor of surgery in the University of Moscow, as its director. In addition, facilities will be offered to students who, desirous of joining the scientific circle of investigators there, have already proved themselves efficient workers in that department of pathological research.

THE very alarming reports which were published by the German Press towards the end of March concerning both the extent and rapidity with which the recent outbreak of an epidemic of enteric fever in Upper Silesia had spread throughout that country, and particularly the serious complications and the high rate of mortality by which it was followed, have prompted the Prussian "Cultusminister" to request Prof. Robert Koch to proceed at once to that part of the German Empire for the purpose of ascertaining the original source of the infection and of adopting some trustworthy measures to check its further present spread, and to prevent, as far as possible, its occurrence in the future. Prof. Koch, it is reported, will now leave Berlin for Beuthen, which is situated near the Polish frontier, where he will, in the first instance, examine the so-called "hygienic station," which was erected there for bacteriological purposes some years ago, whence he will proceed to the other more important places and towns of Silesia with a view to inspecting carefully their present sanitary conditions. It is believed that Prof. Koch will be engaged on his mission for from six weeks to two months; subsequently his report, which, it is understood, will cover all the main points of his bacteriological investigations bearing upon enteric fever, will be published by the Reichsgesundheitsamt of Berlin.

REPRESENTATIVES of several societies interested in archæology met Sir Edmund Antrobus on Friday last at Stonehenge to discuss the details of the resolutions passed at the recent conference in London, and referred to in our last issue (p. 576). The *Times* reports that all the details of the work it is proposed to do with the view of maintaining the stones in a position of safety were fully discussed, and the representatives present unanimously approved all the suggestions made at the London conference. It was decided to proceed with the work as soon as the weather is favourable. It will be carried out under the supervision of Mr. Delmar Blow, assisted by an eminent civil engineer; and nothing in the way of restoration will be attempted. The only object the societies have in view is the preservation of this ancient memorial. The first work to be undertaken will be the raising of the huge monolith, which overhangs the altar stone and is in a most dangerous condition, into an upright position. It is the largest and finest monolith in England next to Cleopatra's Needle. At present it rests on a smaller stone, but there are two large flaws or cracks in it, and if it were to fall it is feared that it would be broken into three parts. The experts engaged in the work will next proceed to examine the stones numbered 6 and 7 on Mr. Petrie's plan, with the view of putting them in a position to support the lintel which rests upon them. The other recommendations of the societies will be carried out in due course; and, in the meantime, Sir E. Antrobus hopes to obtain permission to divert the roadway now passing through the earth-circle which surrounds the stones, and to proceed with the erection of the wire fence approved by the conference.

M. DE FONVIELLE, ex-president of the French Society for Aërial Navigation, delivered an address upon the position and progress of aëronautics in France, at a meeting of the Aëronautical Society held at the Society of Arts on Monday. In the course of the address, M. de Fonvielle referred to several important matters requiring the consideration of meteorologists, astronomers and others interested in scientific ballooning. One refers to the time at which the balloon ascents are made in connection with the International Aëronautical Committee. The balloons are sent up about eight o'clock in the morning, but M. de Fonvielle urged that a better plan would be to let the ascents be made at night, when less disturbing variations of temperature would be experienced. As manned balloons are sent up at the same time as free balloons, it was suggested that by making the ascents at night opportunity would be afforded of making astronomical observations which might be prevented at low levels by cloudiness. Another point which M.

de Fonvielle mentioned was that the ascents should not be made upon a particular day of the calendar month, as they are at present, but in the lunar month, by preference near the time of New Moon. The interference of moonlight with intended astronomical observations would thus be obviated.

Dr. Hergesell, president of the International Aëronautical Committee, has sent us an account of the preliminary results of the international balloon ascents of March 7. Twelve unmanned balloons, three manned balloons and one kite were sent up from various places on the Continent, but the records of three of the unmanned balloons were lost. At Vienna a height of 10,000 metres was reached; the lowest temperature recorded was −62° C. At Moscow the temperatures recorded were −13° C. at starting, −20° at 4400 metres, and −41°·6 at 6650 metres. At Trappes, near Paris, one balloon reached 10,820 metres and recorded −43°; the minimum temperature, −51°·2, was registered at 8792 metres. A second balloon registered −43°·6 at 10,481 metres and −53° at 8891 metres. At Strassburg a height of 10,000 metres was reached, and the minimum temperature recorded was −52°. Perhaps the most noteworthy record is that of a second balloon from Moscow, −12° at starting, −15° at 2700 metres; an inversion of temperature, +2°, occurred at an altitude of 250 metres.

The *Scientific American* states that there is a project on foot for the construction of a movable electric platform on the right bank of the Seine. The platform will be underground, and its length will be about six miles. The route proposed passes under the Avenue de l'Opera, the great boulevards, Boulevard Sebastopol, the Rue Turbigo and the Rue de Rivoli. The new scheme calls for four platforms instead of three, as was in use at the Paris Exposition. The first platform will be stationary, the second will have a velocity of 1½ metres a second, the third 3 metres, and the fourth 5 metres. This will enable pedestrians to have a very rapid means of transit afoot in a portion of Paris which is greatly encumbered by vehicular traffic, for, as all the locomotion is in one direction, persons can walk very fast on the fourth platform, and will be able to cover a great distance. Some means of transit on the streets mentioned is so necessary that it is probable the scheme will be carried into effect.

There have been some discrepancies in recent allusions to the 1885 experiments carried out at Paris with the navigable balloon *La France*, Mr. Chanute, in the *Engineering Magazine*, April 1896, referring to speeds of 14 miles an hour, while Sir Hiram Maxim, in the *Aeronautical Journal*, October 1900, spoke of the speed as about 4 miles an hour, and only a single case of return to the point of departure. A note on this subject appears in the *Aeronautical Journal* for April, from which it appears that the balloon returned five times to its starting point. On referring to the original article in the *Comptes rendus* for 1886, we gather that the speed was estimated at from 4 to 6 metres per second, and probably the discrepancy was due to some confusion in regard to the units.

The Botanical Exchange Club of the British Isles has just issued its annual report for 1899, from which we gather that the number of plants sent in shows a considerable falling off from the average of recent years. It is to be feared that the rival attractions of golf, photography and philately have diverted the attention of many who in former days devoted their spare time to the study of the British flora, and that modern facilities for attending science classes have hardly succeeded in maintaining the interest in field botany and natural history that was shown formerly. Still the report contains many records of interest, notably of the specific and varietal forms of the difficult genus Rubus, which have been studied by the Rev. W. Moyle Rogers, while Mr. F. Townsend has commented on the forms of Euphrasia. The distributor (Rev. W. R. Linton) calls attention to the desirability of members sending not less than ten specimens of each plant, but we question whether a too literal interpretation of this recommendation might not lead to the total uprooting of certain rarities.

Although it has long been known that no actual gas obeys Boyle's law, attention has been chiefly centred round the divergencies which occur at high pressures. It is true that the behaviour of gases at low pressures has received attention from Siljeström, van der Ven, Mendeléeff, Amagat, Fuchs, Krajewitsch, Baly and Ramsay and McLeod, and these experiments have led to the discovery of a discontinuity in the case of oxygen, but the experimental difficulties have led to considerable divergencies of results in other respects. An investigation is now described by Prof. A. Battelli in the *Nuovo Cimento* for January and February, which leads to the following results:—(1) Hydrogen obeys Boyle's law for pressures below one atmosphere down to about 0·2 mm.; (2) Air deviates slightly from the law between 2 and 5 mm.; (3) Oxygen exhibits a discontinuity about 0·7 mm.; (4) Carbonic anhydride at low pressures is compressed more than Boyle's law would indicate, probably owing to absorption by the walls of the containing vessel. With the exception of oxygen, and consequently air, the present investigation does not bring to light any anomalies not attributable to experimental conditions. On the other hand, the existence of discrepancies, representable by the introduction of a discontinuous function into the characteristic equation, is not incompatible with the kinetic theory, but may be attributable to changes in the grouping of the molecules.

The Accumulator Industries Co. Ltd., has brought out a new primary cell, under the name of the "Cupron-Element," in which the electrodes are plates of zinc and copper oxide and the electrolyte caustic soda, or, for special purposes, caustic potash. The E.M.F. of this combination is low, amounting to only about 0·85 volt; but this is compensated for by a low internal resistance. It is claimed that the difficulties hitherto met with in the manufacture of a suitable anode (copper oxide) plate have been overcome, and that a coherent and, at the same time, highly porous plate has been obtained which can easily be regenerated when exhausted by simple exposure to the air. The cell has the advantage that there is no local action when on open circuit. To judge from the discharge curves printed in the catalogue, the cell has a high capacity and is capable of giving continuously a steady current. Of course, a primary battery with zinc as the ultimate source of energy can never be really a cheap way of getting current; but one which gives little trouble, is easily recharged and gives a good steady current, has a considerable range of utility, especially as a means of charging small accumulators.

To the March number of the *American Naturalist* Dr. W. H. Dall contributes an account of the morphology of the hinge-teeth of bivalve molluscs, in which the various systems of nomenclature for these structures that have been from time to time proposed are discussed and contrasted. Many problems in connection with the homology and evolution of these structures still await solution.

In another paper in the *American Naturalist* for March Messrs. Wheeler and Long discuss the males of certain species of ants of the genus Eciton, with figures of several. These ants have the habit of seizing the larvæ and pupæ of other kinds of ants, as well as insects of other descriptions, and storing them up in their nests to serve for food as occasion requires. When the colony removes to another nest the booty is carried with the other *impedimenta*. And if Eciton ants be fed with termites

or the larvæ of other species, many of these termites or larvæ will be carried about or stowed away in some corner of the nest for several days before being consumed.

WE are glad to learn, from its Report for the year 1900, that the Rugby School Natural History Society is in a flourishing condition and continues to make good progress. The requirements of its members render it essential that this body should not confine its investigations and its museum to local subjects, but it may be questioned whether a collection of Samoan ferns is entitled to form one of its exhibits. Two of the members of the Society are endeavouring to emulate Mr. Kearton in photographing the nests of birds in their natural situations, and, judging from the specimens published, may be congratulated on their efforts.

THE twentieth fasciculus of "Papers from the Harriman Alaska Expedition," now in course of publication in the *Proceedings* of the Washington Academy, deals with the nemertean worms, and is illustrated by an excellent coloured plate. During the summer of 1899 exceptionally favourable opportunities were enjoyed of collecting these worms on the Alaska coast south of Bering Sea, and the result has been to add very largely indeed to our knowledge of these organisms. Some thirty-two species were collected by the expedition, of which Dr. W. R. Coe describes no less than twenty-seven as previously unknown to science, while only two of the remainder had hitherto been recorded as denizens of the Pacific. No new generic types were found. For preserving these worms Dr. Coe reports that he found a solution of from two to five per cent. of formalin in sea-water gave satisfactory results so far as the preservation of external form is concerned, although it ruined the nerve and connective tissues.

IN the *Proceedings* of the Washington Academy of March 26 (vol. iii. pp. 111–138), Mr. G. S. Miller describes a collection of mammals made by Dr. W. L. Abbott in the Natuna Islands, lying between the Malay Peninsula and Borneo. Two collections of mammals from these islands have been previously described, the one by Messrs. Thomas and Hartert and the second by Mr. Thomas alone, the material having been obtained by Mr. A. Everett in 1893 and by Mr. E. Hose in the following year. The well-known energy of Dr. Abbott has added largely to the number of species obtained by these collectors, and Mr. Miller describes many of the acquisitions as new, among them being two species of chevrotain and a wild pig. With regard to a discussion that has taken place as to the relationships of the Natuna fauna, the present collection tends to show that there is a greater similarity between the mammals of the Malay Peninsula, Borneo and the intervening islands than has been hitherto supposed. Consequently there is little room for discussion as to whether the Natuna fauna comes nearer to that of the peninsula or of the large island.

IN its Report for the past year the Wellington College Natural Science Society directs attention to the efforts it has been making towards the revival of field work by the establishment of a field-club for the systematic investigation of the local fauna and flora within a twelve-mile radius. The project is worthy of all commendation as being the one important *raison d'être* of local natural history societies. And a special interest and importance attaches to such an investigation at the present time in the neighbourhood of the College. Six years ago the Society published local faunal lists compiled from the records of the previous twenty years. "During that time a great change came over the country just round the College; cultivation, drainage and building have all aided in destroying many plants and insects that used occasionally to be found; and these lists, although interesting as bearing record as to what did occur at one time or another, are now necessarily incomplete; many of the finds are no longer to be found, whilst other and new ones have to be added." It is much to be desired that investigations of a similar nature should be undertaken in other parts of the country where analogous changes have taken place.

PART 4 of vol. xiii. (March 1901) of the *Proceedings* of the Cotteswold Naturalists' Field Club contains an elaborate and well-illustrated memoir by Dr. S. S. Buckman on "homœomorphy" among Jurassic brachiopods. By homœomorphy the author understand "the phenomenon of species nearly alike so far as superficial appearance is concerned, but unlike when particular structural details are closely examined. It is the phenomenon of similarity in general with dissimilarity in details." Dr. Buckman's views are too complicated to discuss in this column, but it may be mentioned that, in his opinion, much confusion has arisen in the description of Jurassic brachiopods owing to failure in recognising the phenomenon in question. To the same publication the Rev. A. R. Winnington-Ingram contributes some notes on polydactylism in cats. The family to which he refers have a cross of the Manx breed, and the supernumerary digits are attributed to reversion to polydactylous ancestors intermediate between fishes and amphibians.

THE way in which the American Anthropological Museums are growing is a continual source of congratulation and at the same time of envy on our part and regret that there is such indifference to the science in Britain. To give one instance of the example set by our American friends, Dr. G. A. Dorsey informs us in *Science* (n. s., vol. xiii. p. 219) that in 1897 the Hopi collection of the Field Columbian Museum for Chicago was comprised within three cases. Thanks to Dr. Dorsey's representations, Mr. Stanley McCormick was induced to purchase for the Museum a very extensive collection formed by Mr. H. R. Voth, who has long been a missionary among the Hopi. Then, in order to render the exhibit exhaustive, Mr. McCormick, with characteristic American generosity, provided the funds for four expeditions which have very successfully investigated the archæology of the Hopi country, with the result that two halls in the Museum containing thirty-four cases are devoted to a demonstration of the ordinary everyday life of the Hopi and their past culture, and a third hall will shortly be filled. The most valuable exhibits are reproductions of nine of the underground altars, with their sand mosaics, which play so important a part in the great nine-day ceremonies of these interesting people. We have nothing in the whole British Empire to compare with this!

DR. THORODDSEN contributes to *Petermann's Mitteilungen* a paper on the earthquakes which occurred in Iceland in August and September 1896. In order to collect material for this report the author first addressed inquiries to a number of residents in the district affected—the southern lowland of Iceland—and in 1897 made an examination on the spot. Dr. Thoroddsen has been able to locate with considerable precision the region of greatest intensity of disturbance, and finds that, as in former cases, the chief centre of origin lay near the boundary between the subsiding lowland and the surrounding highland. The disturbance was, therefore, of tectonic origin; the volcanoes in the neighbourhood—Hekla, Katla and Eyjafjallajökull—remained passive during and after the earthquake shocks.

THE *Geographical Journal* for April contains an analysis of the physical geography of South America, by Col. G. E. Church. The paper, which is to form the introductory chapter of a book on the subject, gives a close comparison of the conditions in North and South America, and shows that "in general, man finds himself confronted by severe conditions in his struggle with

nature in South America. Thus far his efforts to develop and utilise its vast resources have made its commercial history an epic. The thought naturally presents itself that had North America fallen to the lot of the Latin race in the European occupation of the New World, and South America to the Anglo-Saxon, the former might still have maintained its old premacy; for the more rapid progress of the latter may not be due so much to racial superiority as to advantageous geographical urroundings."

The list of additions to the library of the Royal Gardens, Kew, received during last year, occupies eighty-three pages in the *Kew Bulletin* (Appendix ii. 1901) just issued. The titles are printed on one side of the page only, so as to allow the list to be cut up and the slips used by persons and institutions having catalogues based on the Kew catalogue.

Announcement has just been made by a committee of American anthropologists, of which Mr. F. W. Hodge, managing editor of the *American Anthropologist*, is secretary, of the proposed publication of an illustrated volume containing more than hirty folk-tales which were collected and translated by the late Frank Hamilton Cushing during his long and intimate association with the Zuñi Indian tribe of New Mexico. Information and subscription forms may be obtained from the secretary, whose address is Washington, D.C., U.S.A.

The third divisional volume has been received of Thompson's "Gardener's Assistant," a new edition of which, edited by Mr. William Watson, assistant curator at the Royal Gardens, Kew, is in course of publication by the Gresham Publishing Company. Among the subjects dealt with are popular garden plants, greenhouse and conservatory, greenhouse plants, stove plants, orchids, indoor and hardy ferns, succulent plants, hardy shrubs, bedding and floral decorations. Several plates and numerous excellent illustrations accompany the descriptive text.

A large terrestrial globe is an essential piece of furniture for the satisfactory teaching of geography. The ideal globe is in relief, but the price at which such a globe can be well produced s prohibitive to its extensive use. A large globe in which physical features are given prominence is the next best substitute, and this has been produced by Messrs. Philip and Son under the title of "Philip's Physical School Globe." The diameter is nineteen inches, and three forms of mounting of the globe are constructed, namely, one a pedestal for table, another the same with the addition of a graduated half meridian, and the third a tripod stand, with complete meridian and horizon.

The following prices obtained for some of the natural history books from the library of the late Mr. P. Crowley, sold by Mr. J. C. Stevens at his auction rooms on Monday, are of interest:—"Transactions of the Entomological Society," complete set, 46 vols., 38*l.*; "Catalogue of the Birds in the British Museum," vols. 1 to 27, 1874–95, 48*l.*; "The Ibis," 1859 to 1900, with indexes, 42 vols., 75*l.*; "Proceedings of the Zoological Society," 1830 to 1900, 60 vols., 60*l.*; "The Birds of the British Islands," by Lord Lilford, 7 vols., 63*l.*; "Biologia Centrali Americana," 35 vols., 90*l.*; "Birds of Europe," by H. E. Dresser, vols 1 to 8, 1871–1881, vol. 9 supplement, 1895–6, 56*l.*; "Histoire Physique, Naturelle et Politique de Madagascar," by A. Grandidier, 1875–95, 35*l.*; "The Birds of Asia," by John Gould, 7 vols., 1850–1883, 51*l.*; "The Birds of New Guinea, Papuan Islands and Australia," by J. Gould, 5 vols., 1875–78, 45*l.*; "The Birds of Great Britain," by John Gould, 5 vols., 1863, 49*l.*; "Monograph of the Pheasants," by D. G. Elliot, 2 vols., 1872, 53*l.*; "Rough Notes on the Birds observed during Twenty-five Years' Shooting and Collecting in the British Islands," by E. T. Booth, 3 vols., 1881–7, 25*l.*

The additions to the Zoological Society's Gardens during the past week include a Macaque Monkey (*Macacus cynomolgus*) from India, presented by Mr. C. L. Lane; a Mozambique Monkey (*Cercopithecus pygerythrus*) from East Africa, presented by Miss Leah Simmons; a Rufous-necked Scimitar Babbler (*Pomatorhinus ruficollis*), a Golden-backed Woodpecker (*Brachypternus aurantius*) from India, presented by Mr. E. W. Harper; an Indian Python (*Python molurus*) from India, presented by Mr. C. Oscar Gridley; a Chameleon (*Chamaeleon vulgaris*) from North Africa, presented by Mr. C. King; ten Indian Cobras (*Naia tripudians*) from India, ten Reeve's Terrapins (*Damonia reevesi*) from China, ten Roofed Terrapins (*Kachuga tectum*) from British India, ten Blue Lizards (*Gerrhonotus coeruleus*), six Red Newts (*Sperlepes rubra*) from North America, a Red-fronted Lemur (*Lemur rufifrons*) from Madagascar, deposited; an English Wild Cow (*Bos taurus*), a Bactrian Camel (*Camelus bactrianus*), born in the Gardens.

OUR ASTRONOMICAL COLUMN.

Nova Persei.—*Bulletin* No. 16 of the Yerkes Observatory contains a report from Prof. Hale on the work done in connection with the new star in Perseus. An examination of the Nova with the 40-inch refractor on February 24 failed to show any trace of nebulosity. Photographs of the spectrum were obtained on eight nights, using Erythro plates, with spectrographs of one and three prisms respectively. These extend from H_a in the red to the ultra-violet H_i; comparison spectra were taken of titanium, hydrogen and sodium. Photographs of the region of the Nova have been obtained with the 40-inch telescope, and will be subsequently measured at Columbia College Observatory. The brightness of the star has been measured by the wedge photometer.

A Remarkable Group of Nebulous Spots.—Prof. Max Wolf, of Heidelberg, writes to the *Astronomische Nachrichten* (Bd. 155, No. 3704), describing an appearance of small nebulous bodies surrounding the star

$$\left.\begin{array}{l}\text{R.A.} = \ 12^{\text{h}}\ 52^{\text{m}}{\cdot}6 \\ \text{Decl.} = +\ 28^\circ\ 42'\end{array}\right\}(1855{\cdot}0).$$

They are so close together as to form a remarkable feature in the field of view. He was able to count 108 in a circle about 30′ of arc in diameter. Some of the fourth or fifth magnitude showed a central condensation, more or less elongated, while other fainter ones had a roundish form.

Stonyhurst College Observatory.—The annual summary of the meteorological, magnetical and other observations made at the Stonyhurst Observatory in Lancashire has just been issued by the director, Father Sidgreaves. Special co-operation with the International Meteorological Committee has been in force since November, observations of clouds and wind being made throughout three successive days of each month; on the second of these days balloon ascents are made by representatives of the Committee.

The work of comparison between individual sun-spots and terrestrial magnetic storms has been concluded and published in the *Memoirs* of the Royal Astronomical Society. This covers the period of eighteen years from January 1881 to December 1898.

Experiments are in progress in connection with the improvement of the present means of obtaining stellar spectra, quartz lenses being now employed, so that more of the ultra-violet region will be photographed.

Catalogue of Double Stars.—Vol. i. of the *Publications* of the Yerkes Observatory consists of a general catalogue of 1290 double stars, discovered from 1871–1899 by Prof. S. W. Burnham. The stars are arranged in order of their right ascensions, full particulars being given of all the micrometrical measures of each pair. The work has been done with telescopes varying from 6 inches to 40 inches in aperture, the greater number (451) of the discoveries having been made with the smallest instrument.

INDIAN FORESTRY.[1]

BEFORE retiring from the Indian Forest Service the author obtained the sanction of Government to the publication of this volume, which contains a brief description of the forests and a sketch of the introduction and growth of forestry in the British Indian Empire. In the preface he says: "My career in the Indian Forest Service has extended over thirty-three years, and though I was not in the country when regular forest conservancy was first introduced, I arrived when it was still quite a small sapling, and I have seen it grow to the mighty tree it is at present, under the wide-spreading shadow of which I have grown old."

Mr. Ribbentrop is one of the two young German forest officers whom the writer of these lines in 1866 was permitted to engage for the Indian Forest Service. He came from Hanover, where he had received his professional training, and had worked under the late Forst-director Burckhardt, one of the most eminent foresters of his day in Germany. The other was Dr. W. Schlich, now principal professor of forestry at Coopers Hill, whose excellent "Manual of Forestry" has repeatedly been discussed in these columns.[2]

Obviously it is out of the question, within the space here available, to follow the author through his description of the forests and through his account of the earlier stages of forest administration in India; it must suffice, briefly, to state a few of the principal results accomplished and to indicate the lines on which, in the interest of the 294 millions inhabiting the large British Indian Empire, further progress in this business ought to be made. As it will be satisfactory to deal with the last figures available, those for 1898–99 will, in a few cases, be quoted, the book giving only those to the end of 1897–98.

In 1899 the area of reserved Government forests in the different British provinces of India aggregated 84,148 square miles, or 54,000,000 acres, more than the total area of England and Ireland together. The State forests of the German Empire only aggregate 16,400 square miles. These are very large figures, but the British Indian Empire is a very large country. Of the total area of the German Empire the State forests occupy 8 and in the British provinces of India the Government reserved forests occupy 8·6 per cent. of the total area. At first sight this seems a most satisfactory result; the Indian State forests constitute a slightly higher percentage than those of the German Empire, a country where the necessity of good forest management is acknowledged to the fullest extent. Besides the 16,400 square miles of State forests, however, there are large areas of Crown forests, of forests belonging to public corporations, there are, further, 8400 square miles of communal and 26,000 square miles of private forests. All these, excepting a small proportion of the private forests, are managed as efficiently as the State forests. The Governments in the different States have shown the way, they have taken the lead in the management of their forest domains, and the other proprietors have gradually followed suit. The total forest area of the German Empire amounts to 54,000 square miles, or 26 per cent. of the entire area. Sixty years ago Germany was an important timber exporting country, since then, as a necessary consequence of the development of industries and manufactures, and the increase of wealth, the imports have gradually exceeded the exports. Now it is only second to Great Britain in the list of timber importing countries, and this is so, although the annual production of wood per annum is increasing steadily, as the result of the great progress made in forest management. The total annual production of timber and firewood of the German forests is estimated at 38,000,000 tons, and this is supplemented by an import of 4,600,000 tons. The material progress of the country would not be possible had it not the large home production to fall back upon. There are other forest lands in India which are nominally under the control of the Forest Department, viz. 8800 square miles of protected and 27,700 square miles of unclassed forests, but in these areas protection is nominal, and they are not managed with a view to a sustained yield. The reserved forests are the only trustworthy resource for the future, and these, as stated, only form 8·6 per cent. of the total area. One of the excellent maps appended to the book illustrates the distribution of these forests in the different parts of the Empire, and this map shows at a glance the very unequal distribution. Berar has 23, the Central Provinces have 22, Burma has 9, but the North-West Provinces and Oudh have only 3·6 and the Punjab only 2 per cent. of Government reserved forests.

Nevertheless, it is an important point gained that so large an area is at the disposal of Government and that it is managed, so far as circumstances permit, with the view of obtaining from it a sustained and, if possible, steadily increasing yield of timber and other forest produce. The reader will ask the question whether it is right to lock up so large an area and to prevent the extension of cultivation, the establishment of fields within that area, in a country the population of which is mainly agricultural and is increasing steadily, which, indeed, is increasing with alarming rapidity in some districts and provinces.

What, then, has been the object in constituting this large area of reserved forest, and what is the object in maintaining it under forest? The author holds that the old records of Indian history, down to the invasion of the Punjab by Alexander the Great, prove that in those days extensive forests existed, and that the wholesale destruction of these forests has had the most deteriorating effect on the climate. He does not go so far as to maintain that by afforestation of large tracts the climate might be improved to such an extent as to stop the recurrence of these terrible seasons of drought, which are one of the chief difficulties with which the Government of India has to deal. It is evident, however, that his thoughts run in this direction. Doubtless it is not safe to lay stress upon such arguments. We may readily assent to the words of the author: "In a warm climate the denudation of a country diminishes its moisture and consequently its fertility" without indulging in the hope that in seasons of drought the presence of forests will increase the rainfall.

The local influence, however, of well-stocked forests in India no intelligent person, who knows the country, will deny. Well-stocked forests afford shelter to fields, to man and beast against the scorching winds of the hot season, and the dew is heavier in their vicinity. Of much greater importance still is the effect of well-stocked forests in regulating the surface drainage, in maintaining an even water supply in springs and streams, in preventing the denudation of hillsides, the silting up of rivers, and the destruction of fields and gardens in the plains by the sand and silt washed down from the hills. The author quotes a description of the Ratnagiri district on the western coast of the Peninsula, south of Bombay:—"Under a rainfall between 100 and 150 inches a year, this district is almost bare to the crest of the ghats, the result of fires, grazing and shifting cultivation. The four principal streams, which, rising in the Ghat Mountains, run a short course to the sea, were all navigable formerly, and were important for the trade of the country. Small boats still run, but the streams are gradually silting up, because the hills at their headwaters have become denuded."

In the Hoshiarpur district of the Punjab the Siwalik range of hills stretches from the Bias to the Sutlej river in a south-easterly direction. These hills consist of a very soft friable sandstone, alternating with strata of loam and clay. Formerly these hills were fairly well wooded. In 1846 they became British territory; the consequence was a rapid increase of population, a great demand for wood and charcoal in the fertile plains below, and the influx of a floating population of graziers with large herds of cattle. The result was complete denudation of these hills; the loose soil, no longer protected by vegetation, was washed down, broad rivers of sand spread into the plains below, and the end has been that fields and gardens of 940 villages, once prosperous, are now covered with sand, which has laid waste upwards of 70,000 acres of fertile lands. This district, rich formerly, is now traversed by numerous broad parallel sandy belts, cut out of the fertile and crop-bearing area.

Efficient protection of the reserved forests was only commenced a comparatively short time ago, and yet the author is able to state numerous instances from different parts of the country, in which protection has completely changed the character of the torrents and streams taking their rise in the forests. After rain, the water no longer rushes down, carrying sand and silt with it; the channels have been confined into permanent beds; they have become narrower and deeper, and the old beds to the edge of the channel have become stocked with grass and thousands of seedlings. The regulation of the underground waterflow takes more time, but Mr. Ribbentrop is able to report a case where, near a protected reserve in Ajmere, water is now found at the depth of 15 feet, where formerly it was not

[1] "Forestry in British India." By Berthold Ribbentrop, C.I.E., late Inspector-General of Forests to the Government of India. Pp. ii + 245, with 4 maps. (Calcutta: Office of the Superintendent of Government Printing, India, 1900). Price 4*s*. 6*d*.

[2] NATURE, vol. xli. p. 121; vol. xliv. p. 265; vol. liii. pp. 510, 535.

reached under 25 feet. The denser vegetation, which is the result of efficient protection, has everywhere counteracted erosion, has prevented landslips and sudden floods.

These indirect advantages of forest conservancy are obvious and of very great importance, but in most cases the chief object aimed at has been the production of timber, bamboos, firewood and other forest produce. The produce yielded by the forests furnishes the revenue, which enables Government to maintain a proper management of these estates. In old times the requirements in wood and timber of the people and of Government were met without difficulty. But with the increase of population, the growing wealth of the people, the construction of railways and other public works, the demands upon the forests increased. Within reach of the railways and elsewhere, forests disappeared with incredible rapidity. The threatening scarcity of timber and wood compelled the Government to take action. The author gives an interesting account of the efforts made in the beginning of last century on the western coast to provide a permanent supply of teak timber for ship-building, efforts which failed completely, because most injudicious and unjust attempts were made to interfere with private property. In the same way the history of the Tenasserim forests is told, the conservancy of which was urged by Dr. Wallich in 1827, and which were gradually, but effectively, destroyed through a series of mistaken measures. In the adjoining province of Pegu, at the command of Lord Dalhousie, and under the guidance of Sir Arthur, then Major, Phayre, in 1856, a systematic management of the teak forests was introduced, ensuring the certainty of a permanently sustained yield of teak timber, while the friendly co-operation in the business of the Karen and Burmese inhabitants of the forests was secured, by giving them profitable and permanent employment in forest work. When, after five years of hard work, a steadily increasing surplus revenue from the forests had been realised, proving beyond question the great value of those domains, the timber merchants of Rangoon, naturally anxious to get this valuable property into their hands, had prevailed upon the Government of India to grant their request, and accordingly in February 1861, orders were issued to the Commissioner of Pegu to throw open the forests to private enterprise. These orders, which were praised as most enlightened and liberal by Anglo-Indian public opinion, seemed at the time to put a stop to all progress in this direction. Fortunately, at a later date, the greed of the permit-holders under the new arrangements, resulted in breaches on a large scale of the terms of their permits, the consequence of which was, that the permits were cancelled.

Not more steady was the progress made in other provinces in attempting to place the management of the forests in such a position as to enable them to furnish the needful sustained yield of wood and timber. When Sir John (afterwards Lord) Lawrence landed at Calcutta in January, 1864, as Governor-General, he had determined to stamp out this new-fangled scheme of forest administration, which would weaken the position of the chief civil district officer by taking away from him the charge of the forests. It was only through the fortunate accident that Sir Richard Strachey, at the time secretary to the Government of India in the Public Works Department, who had some time previous taken charge of the forest business, gradually gained influence over the Governor-General to such an extent, that actually in Sir John Lawrence's reign the forest establishments under the Government of India were placed on a regular organisation.

Apart from reckless cutting, the improvement of the forests was impeded by two old-established practices, grazing and the jungle fires of the hot season. Two important and interesting chapters are devoted to these subjects, to the efforts made to regulate grazing and to protect the forests against fire. Here it must suffice to state that systematic fire protection was commenced in the Central Provinces in the hot season of 1865. Colonel Pearson, then Conservator of Forests in that province, had serious doubts on the subject; he knew that any attempt to interfere with this ancient institution, which cleared the ground of inconvenient grass and underwood, would be distasteful to all, Europeans as well as natives. With the powerful support of Sir Richard Temple, then Chief Commissioner of the Central Provinces, he made the attempt. He selected the Bori forest in the Satpura range, a district most favourably situated for the experiment. He succeeded, and within a few years he saw the condition of the forest entirely altered. The extensive grasslands and smaller blanks in the forest gradually filled up from the edge with coppice shoots and self-sown seedlings, the soil, which hitherto had been hardened and sterilised by the annual fires became fertile, the trees increased rapidly in height and girth, and the fresh shoots of the bamboo became taller and stouter. Gradually this difficult work was taken in hand in all provinces, and in 1899 no less than 29,492 square miles were successfully protected against fire, or one-third of the total area of reserved forests. The expense of these operations latterly has been between ten and eleven rupees per square mile.

The question will now properly be asked: Who pays for all this business? Forest revenue and expenditure have increased steadily ever since forest business was properly organised. In 1898–99 the results were as follows:

Revenue ...	Rs. 1,90,38,520,	or	1,270,000*l*.
Expenditure ...	,, 1,00,33,920,	,,	670,000*l*.
Surplus ...	,, 90,04,600,	,,	600,000*l*.

This, it is true, is only a small contribution to the annual revenues of the British Indian Empire, which in the same year amounted to 1,01,40,00,000 rupees. But it is something, and the surplus is increasing steadily. Certainly it must increase, for at present it only amounts to 2·7*d*. an acre. In some provinces, fortunately, the surplus is higher. Since the annexation of the kingdom of Burma the reserved forests in this province are:

7,679 square miles in Lower Burma.
7,988 ,, ,, in Upper Burma.

Total 15,667 square miles.

Both in Upper as well as Lower Burma teak timber is the principal and most valuable produce of the forests. The teak forests of Upper Burma had been leased by the King to powerful firms at Rangoon under the vaguest conditions. The lessees were only liable to the payment of a lump sum per annum, without reference to the amount cut by them. Under these conditions the utter devastation of the forests within a short time was inevitable. It has been Mr. Ribbentrop's privilege, after the conquest of the country in 1886, to induce the Government to claim the right of interference, and it is entirely due to the tact and determination with which he conducted the negotiations that a settlement was arrived at, under which no trees can be cut that have not been selected and girdled by the Forest Department. Thus this valuable property was saved from ruin, and it is satisfactory that the last of the leases will shortly expire. The surplus realised by the Burma Forests in 1899 was 59,24,000 rupees, corresponding to 13*d*. an acre. This is better than the amount realised from the whole reserved forests of the British Indian Empire. But even this is a poor result as compared with the yield of properly managed forests in Europe. Of all States of the German Empire, Prussia has, owing to unfavourable soil and climate, the least productive forests, and the average net yield of the State forests is only five shillings an acre, while the State forests of Saxony yield twenty and many forest ranges in that country yield thirty to forty shillings an acre. Much progress, therefore, has still to be made in improving the condition and productiveness of the Indian forests before they can hold their own in comparison with the forests of Europe. This result, however, will be attained provided a sound and vigorous forest policy is continued.

Besides timber, wood and bamboos there are numerous other substances, such as tanning materials, gums and caoutchouc, necessary for the every-day life of the people and required for the commerce of the world, which are produced and will be produced on a much larger scale, provided the forests are efficiently protected and properly managed. From all this a growing surplus revenue may be obtained. There is, however, a class of forest produce more important than all these for the welfare of the country, which cannot be expected to contribute very largely to the surplus forest revenue. This is grass and cattle fodder.

In a hot climate, except in districts with an exceedingly heavy rainfall, a better crop of grass is produced under the shade of trees than in the open, and this is particularly the case in seasons of drought, to which, unfortunately, large portions of India frequently are subject. In the dry climate of Rajputana numerous chiefs and princes had from time immemorial established game-preserves, chiefly as cover for pigs. The forest growth in these preserves was carefully protected, and during the terrible famine

which devastated that country in 1867, 1868 and 1869, they furnished an abundance of grass and branches of trees to feed the cattle of the neighbouring towns and villages. Two small British districts, Ajmere and Merwara, are situated in the midst of these native States of Rajputana. Here the whole of the waste and forest lands at the disposal of Government had, at the settlement of 1850, been handed over to the villagers, the State relinquishing its rights in these lands. The results of this "liberal" policy had been disastrous. The hills had become denuded, the timber was sold, the wood was used and these lands had become utterly barren and unproductive. For their crops the people of these districts almost entirely depend upon irrigation. The water is furnished by numerous ponds or tanks, formed by embankments thrown across valleys at convenient points. Many of these tanks are old, others have been built since the country came under British rule. The scanty rainfall in these districts does not come down continuously, but in a small number of heavy showers. The rain rushed down the denuded hillsides in torrents and, instead of filling the tanks slowly but steadily, burst the embankments or filled the tanks with the silt which the floods had brought down. These districts the writer visited in December 1869. The cattle had perished, the people had fled, large villages were entirely deserted, and the country was almost depopulated by these years of drought and famine. Adjoining the district of Merwara on the east side is the territory of the Thakur of Bednor, a feudatory to the Maharajah of Udaipur, and the contrast was extremely surprising—in British territory the hills denuded, in Bednor the hills wooded, the forest having been carefully protected. From the top of Bairat Hill, on January 2, 1870, we looked down upon the town, with its large tank and beautiful groves of fruit trees, and here the Thakur's eldest son, who had the management of the forest lands, told the writer how the Nasirabad charcoal contractors had come, offering large sums if he would allow them to cut. He had refused and would always refuse their request, knowing well that the grass in the forest and the branches of the trees had saved the cattle of Bednor in seasons of drought, and that the water supply in the tanks, upon which the fertility of the country depended, was maintained by the forest growth on the hills.

After several years' hesitation, action was at last taken, in 1874, to remedy the mistakes which, with the best intentions, had been made in 1850. The Ajmere Forest regulation was passed, which gave the Chief Commissioner of those districts power to take up any tract of waste or hilly land as a State forest, granting the people who had formerly had an interest in that land the right of cutting grass and wood in it for their own requirements and a liberal share in the net proceeds from the management of these lands. This measure, at first sight, might be termed a confiscation of rights deliberately granted. In reality, however, the proprietary rights had at the settlement not been granted to individuals, but to the village communities. They were communal lands, and as such public, not private, property. Government, therefore, as the guardian of all public interests, had the duty to interfere. This small measure, had it been properly followed up, might have been one of the most beneficial measures passed in the reign of Lord Northbrook. Unfortunately, only 139 square miles, or 5 per cent. of the total area, have been demarcated as State forest in Ajmere-Merwara. And worse than this, grazing was frequently allowed without real necessity, and consequently protection remained incomplete. Nevertheless, with all these drawbacks these reserves are now very fairly stocked with trees and shrubs, and they have proved a great protection to these districts in times of drought during the last twenty years.

In the famine, which affected a large portion of the Bombay Presidency in consequence of the short monsoon of 1896, operations were undertaken on a large scale to provide cattle fodder from the forests to all districts which needed such help. Mr. Allan Shuttleworth, the Conservator of Forests, organised and directed these operations. Presses were set up near the forests, roads were constructed, hay was made and pressed in 80 lb. bales, which were despatched by train, and were sold at cost price at depots all over the affected districts. The same plan was pursued in the late famine, and has also been adopted in other provinces. Grain can easily be sent to districts affected by scarcity, the provision of cattle fodder is more difficult, and in previous famines the loss of cattle has always been the chief calamity. When at last rain falls and no cattle are left to plough, the distress is terrible. Millions of cattle have been saved by these measures, and it is to be hoped that the ruling authorities in India will always bear in mind that if in seasons of drought the forests are to be in a position to furnish cattle fodder on a large scale, they must in ordinary years be efficiently protected against fire and must not be indiscriminately opened to cattle.

Besides the areas which are classed as forests, there is in each province a large extent of waste, aggregating upwards of 380,000 square miles, or considerably more than one-third of the entire area of the British provinces. At present these waste lands furnish wretched pasture, the scrub and isolated trees upon them yield fuel, and, on a small scale, wood for building and agricultural implements. One of the most important, but at the same time most difficult, tasks awaiting Indian foresters in the future is to undertake the management of these lands. On a small scale something in this direction has been done by the formation of canal plantations, and the establishment of fuel and fodder reserves in a few districts. But the work must be taken in hand on a much larger scale and on a methodical system in all provinces. Under good management these lands will produce heavier crops of firewood and cattle-fodder. At present manure is used as fuel in most districts, and the result is, in spite of the skill and industry with which the Indian peasant cultivates his land, an exceedingly poor yield of crops. In his report on the improvement of Indian agriculture, Dr. Voelcker justly urges the establishment on a large scale of fuel and fodder reserves, in order to supply wood to take the place of cow-dung as fuel. "If wood," he says, "could be made to take the place of dung for fuel, we should soon come to realise that more wood means more manure, that more manure means heavier crops and an increasing fertility of the soil."

It is not impossible that these measures may eventually lead to the formation of village forests. Experience has shown in Germany, in France and in other countries of Europe, that municipal self-government of towns and villages develops in a healthy manner where these municipalities have landed property, provided it is well and efficiently managed. The communal forests in these countries contribute largely to the prosperity of the agricultural population. They furnish all the wood and timber the villages require, and the sale of the surplus yields a steady annual income, in many cases sufficient to cover the charges of the municipality for roads, schools, churches and other purposes.

In a number of interesting chapters the author explains the nature and extent of the rights which Government possessed in the waste and forest land of the different provinces at the time that the State forest reserves commenced to be established. The British Government had legally succeeded to the rights actually exercised by the former rulers of conquered or ceded States at the time of conquest or cession. Consequently, the unoccupied waste, including forests, as a rule, was the property of the State. In these waste and forest lands, however, the people had grazed their cattle, had cut wood and bamboos for their use, and had cleared land for shifting or permanent cultivation. Under the former native Governments the forests had thus been used by the people, not as of right, but subject to the good pleasure of the ruler. When the preparation of proper forest laws for the different provinces was considered, between 1869 and 1878, the most important question was, to what extent this long-continued user of the Government forests should be regarded as constituting a prescriptive right; and it was deliberately settled that the customary user of the forests under British rule must be held to constitute a prescriptive right. On the other hand, it was acknowledged that Government, as the guardian of all public interests, must insist upon the regulation of these rights, so as to render possible a good management of the reserved forests in the interests of the country.

It was held that the growth of forest rights in India had been analogous to the growth of similar rights of user in Europe, and consequently that the legal provisions for regulating them or, in case of need, for extinguishing them by means of suitable compensation, must be analogous to forest laws made in Europe.

By the Indian Forest Acts the duty of deciding which claims shall be admitted as a right, as well as the regulation and commutation of rights thus admitted, is entrusted to special officers, styled forest settlement officers, and an appeal from their decisions is provided. Under the procedure prescribed by these acts, the 84,148 square miles of reserved forests have been settled. In many cases was it possible to extinguish the rights by suitable compensation; in others the forest remained burdened with rights to pasture or the cutting of wood, but these

rights were strictly defined in regard to area, the number and description of cattle admitted to graze, and the amount of timber to be cut. In many instances the settlement officers have gone far beyond the requirements of the law; they have often been disposed to place heavy burdens upon the Government forests, in order to make matters as comfortable as possible to the people in the vicinity. Especially in regard to pasture, the tendency of most Governments in India has been to insist on cattle being admitted to graze in the forests far in excess of what was prescribed by the forest settlement. Young forest growth cannot come up under heavy grazing. In seasons of drought, as a matter of course, the forests must be, and are, always thrown open. But if this is done in ordinary seasons, the forests cannot improve, and cannot provide what is wanted in times of scarcity.

In these circumstances agitation against forest administration is of frequent occurrence. In his delightful and most important work, "Forty-one Years in India," vol. i. pp. 441, 442, Lord Roberts states: "Amongst the causes which have produced discontent of late years I would mention our forest laws and sanitary regulations, our legislative and fiscal systems—measures so necessary that no one interested in the prosperity of India could cavil at their introduction, but which are so absolutely foreign to native ideas that it is essential they should be applied with the utmost gentleness and circumspection. . . . . The proceedings and regulations of the Forest Department, desirable as they may be from a financial and agricultural point of view, have provoked very great irritation in many parts of India. People who have been accustomed from time immemorial to pick up sticks and graze their cattle on forest lands cannot understand why they should now be forbidden to do so, nor can they realise the necessity for preserving the trees from the chance of being destroyed by fire, a risk to which they were frequently exposed from the native custom of making use of their shelter while cooking, and of burning the undergrowth to enrich the grazing."

In these words Field-Marshal Lord Roberts faithfully expresses the views of many leading public men in India. And yet the development of the British Indian Empire, through railways and telegraphs, through extended irrigation, the steadily growing wealth of its inhabitants, necessitates the maintenance and improvement of its forests, while the persistent growth of the population, in spite of famines, cholera and plague, demands that the large areas of waste lands should produce more cattle-fodder and more firewood. These are demands which cannot be resisted.

A detailed account is given of the Dehra Dun Forest School, which was established in 1878 for the professional training of native forest officers. Of the first director of that institution, Captain (now Colonel) F. Bailey, R.E., the author justly states that it was entirely owing to his exceptional powers of organisation, energy and ability that the new institution took healthy root from the outset. It has been explained at the outset of this article that in 1866 two young forest officers from Germany, Dr. Schlich and Mr. Ribbentrop, were engaged for the Indian forest service. In the same year arrangements were made for the professional training of young Englishmen in the State forests of France and Germany. The first selection was made in 1867, and the first men trained under this system joined their province in 1869. Since then a varying number has been sent out annually. In 1887, after the arrangements in France and Germany had come to an end, the first men arrived, who had been trained under existing arrangements at Coopers Hill. Altogether, until 1899, 207 professionally trained men have gone out, of whom in that year 152 were still in the Indian Forest Service. This number obviously is wholly insufficient to provide for the management of 84,000 square miles of reserved forests. Moreover, the small surplus revenue yielded by these forests would make it out of the question to employ English officers for their management. In the State forests of the kingdom of Saxony, the mean area of a forest range or executive charge is 4000 acres. The executive officer, here styled Oberförster, receives the same professional training, and has the same social standing, as the higher forest officers to whom he is subordinate. Every member of the superior Forest Service begins his career as assistant to the Oberförster, and his first appointment to a responsible post is that of executive officer. This organisation ensures efficiency, because the Oberförster has a reasonable chance, by distinguished service, of rising to the highest appointments in the department.

An organisation as simple and effective as this is impossible in India. The revenue of the forests is too small. Further, the officers must necessarily belong to two classes, expensive Englishmen for the higher appointments, and natives at lower rates of pay for the executive charges, and these two classes cannot be amalgamated. Four thousand acres in Saxony yield a net revenue of 4,000*l*. at 20*s*. an acre; the area required to produce a similar revenue in India would be so large as to be quite unmanageable for one executive officer. Thirty square miles, or 19,200 acres, would be a large but still manageable area in India. From 1888 to 1899 the surplus has doubled, and it is not unreasonable to expect that in 1910 it will amount to 6*d*. an acre. At that rate 30 square miles would yield an annual surplus of 480*l*. By that time there ought, therefore, to be 2800 professionally trained forest officers for the executive charge of these forest ranges. The actual number of forest rangers in the different provinces at present (July 1, 1900) is 425. The organisation, therefore, of executive charges is far from complete. To a great extent the executive management of these estates is at present in the hands of the superior controlling and directing officers, who do the work through the agency of forest guards and other protective officers, men who have received no professional training.

The chief difficulty at present is, that the men who enter the Dehra Dun Forest School belong to a lower social stratum than is desirable. And this will continue until means are found to give forest rangers reasonable prospects of promotion. Something in this direction has been done by establishing a provincial branch of the superior Forest Service, so that from time to time a few really distinguished forest rangers may be promoted. And when the advantage of relying mainly upon native agency in forest business has been fully recognised, means doubtless will be found to improve the prospects of advancement for native forest rangers. No possible political difficulty can arise through employing natives of India in the higher branches of the forest service, and hence it seems right to use this department to make the experiment.

Sir Thomas Munro, one of the most distinguished Indian statesmen in the early part of last century, while Governor of the Madras Presidency, wrote as follows on December 31, 1824: "All offices that can be held by natives without danger to our power might with advantage be left to them," and further on follow remarks to the following effect: "To improve the character of the natives we must open the road to wealth and honour and public employment." Since 1824 the British Indian Empire has not only increased enormously in extent and population, but good government, the security of persons and property, the impartial administration of justice, the growth of commerce and manufactures, irrigation works, roads, telegraphs, railways, and by no means least, schools and colleges, all this has brought about a tide of progress which cannot now be stemmed. But the blessings of progress will be valued more by the people if they are not all dispensed by the hand of the foreigner, if natives themselves are the agents, to a greater extent than is the case at present, in the undertakings which contribute to their well-being.

Mr. Ribbentrop is not an advocate of these plans, yet on several occasions he bears testimony to the excellent work done by natives of India, provided they have received a good professional training in surveying or forestry. A weighty objection is raised by parents in this country that plans like these will take the bread out of their sons' mouths. Latterly from six to eight men, who had received their professional training at Coopers Hill have been sent out annually. It may be regarded as certain that, if all goes well, the number required will increase largely, not only because the management is gradually becoming more intensive, improving the yield capacity of the forests and augmenting the revenue, but also because a constantly increasing number of Indian forest officers are required in native States and other countries, such as Siam, and in the British Colonies. Even should a few more appointments be filled up by the promotion of native forest rangers, the number of men required from Coopers Hill will not diminish but will increase. And surely it is better that a policy should be followed which will tend to place British rule in India upon a safe foundation than that a few more appointments should be available for young men at home. The beneficial effects of forestry will not be fully realised until it ceases to be an exotic plant. The educated natives of India must feel that they are the allies of the British Government, and this can only be brought about by giving them

a larger share in all works undertaken to promote the welfare of their country.

The author does not claim to be a botanist, nor does Dr. Schlich, who preceded Mr. Ribbentrop, nor does their successor, Mr. H. C. Hill, the present Inspector-General of Forests. It is necessary to mention this because in England, also among scientific men, the opinion prevails that forestry is a branch of botany, and that a forester who is not a botanist cannot claim to be a scientific man. Dr. Schlich's great merit while holding the appointment in India was to organise that branch of forestry which deals with the plans regulating the working of the forests, a business which is based more upon mathematics than upon botany. Mr. Ribbentrop's great achievement has been to study and correctly to appreciate the peculiar sylvicultural requirements of the great variety of trees and bamboos with which the forester has to deal in India. Through his labours the management of teak, of sal, sissoo, deodar, and of other important trees when growing by themselves or in company with other kinds or with bamboos, their regeneration, natural or artificial, and their subsequent treatment under different conditions of soil and climate, is much better understood now than it was twenty years ago. These are great results, which, provided no retrograde measures are adopted, will bear fruit in steadily increasing the productive powers and capital value of the forests, and will contribute largely to the welfare of the millions inhabiting the British Indian Empire.

DIETRICH BRANDIS.

SUBMARINE BOATS.

THE building of five submarine boats for the British Navy not only forms quite a new departure but also, perhaps, the advent of the nucleus for an instrument of war of novel design. The boats (says *Engineering*, March 29), which are being built by Messrs. Vickers, Sons and Maxim, Ltd., are of the *Holland* improved type and are 63 ft. 4 in. in length over all, 11 ft. 9 in. beam, and 120 tons displacement submerged, and they will be capable of expelling torpedoes either with the boat at rest, during the run on the surface, or steaming at any speed submerged. When running on the surface the boats will be propelled by a gasoline engine (of marine type, inverted, and with four single acting cylinders). The amount of fuel carried will suffice for a run of about 400 miles with a maximum speed of about 9 knots, and when submerged an electric motor of the waterproof type, worked with storage batteries, will give the vessel a speed of seven knots, which can be maintained for four hours. The general operation of the boat is given as follows:—"Before it is desired to make a dive, the boat is brought to 'awash' condition, with only the conning tower ports above the water. The dive is then made at a small angle until the proper depth is reached, when by automatic means the boat is brought to a horizontal position. After the discharge of the torpedo from the fixed bow tube, the compensation for the weight of the torpedo is made automatically, causing only a slight change of trim for a few seconds. Provision is made for quick rising and diving, the time of appearance of the conning tower above the water being dependent on the skill of the navigator." In the United States Navy the *Holland* has undergone most exacting trials and has proved herself "stable in service working," and it is here we get the most convincing testimony, where Admiral Hitchborn, chief constructor in the United States Navy, states in his official report, "The *Holland* has shown herself capable of such complete control in the vertical plane that she may be kept within a few inches of any desired depth while moving, or brought to the surface and taken under again in a very short time: her direction and control in the horizontal plane on the surface is effected with the same facility as any other craft, and submerged is limited only by the difficulties of vision: her crew are provided for on board with reasonable comfort and perfect safety for such periods as she may be in service and working either upon the surface or submerged; and her armament, consisting entirely of torpedoes, gives her great offensive power."

THE CURRENTS IN THE GULF OF ST. LAWRENCE.

IN a former article (January 24, 1901, p. 311) we gave a summary, from a pamphlet recently issued, on the currents in the Gulf of St. Lawrence, in which we noticed some points of general application to similar researches elsewhere. This pamphlet, issued by the Department of Marine and Fisheries, Canada, gives concisely the results of investigations in the summer seasons of three years in that Gulf, conducted by Mr. W. Bell Dawson, in charge of the Survey of Tides and Currents. It is primarily for the benefit of practical seamen; but it also contains an explanation of the hydrography of the Gulf, on which this Survey has thrown considerable light; and it is this part that we now summarise.

General Characteristics of the Gulf of St. Lawrence.—With the exception of the currents in the various straits and near the heads of the bays, the currents met with in the open Gulf seldom exceed one knot. They are, therefore, the more easily influenced by strong winds, especially at the surface of the water. Currents which have a greater speed than this are found in Belle Isle and Cabot Straits, in Northumberland Strait, off the Gapsé coast, in the Gut of Canso, and locally in channels between islands and at the mouths of rivers.

The water of the Gulf may be roughly divided by a line running from South-west Point of Anticosti to the middle of Cabot Strait. Along the south-western side of this line the water has a lower density, as it is apparently made a little fresher by the outflow of the St. Lawrence River. To the north-east of this line, throughout the north-eastern arm of the Gulf, the water has the same density as in the open Atlantic.

The general drift of this water of lower density is outward, towards the Atlantic. This gives rise to two constant currents, one at the mouth of the St. Lawrence along the Gaspé coast, which may be called the "Gaspé Current," and the other on the west side of Cabot Strait around Cape North, which may be called the "Cape Breton Current." A third constant current is found on the west side of Newfoundland, making north-eastward from the Bay of Islands towards Rich Point.

It is to be noted that in calling these currents constant it is only meant that they usually or most frequently run in the one direction. During certain winds they may be much disturbed, or their direction may even be reversed.

Temperature.—It appears that in general the temperature of the surface water merely rises with the progress of the season; and it is also natural that the water should become warmer to a greater depth as the season advances. Even this has its limitations, however; as at a depth of 50 fathoms no greater rise in temperature has yet been found than from 32° to 34°, between the month of June and the end of September.

At all three angles of the Gulf it was found that the coldest water forms a layer between the depths of 30 and 50 fathoms. In the vicinity of Belle Isle Strait, the same low temperatures are also found at these depths; although there the temperature towards the surface is relatively lower, as a rule, than in other regions. It is probable that this cold layer extends very generally over the Gulf area. Below this cold layer, in the deep channel of the Gulf, the temperature from 100 to 200 fathoms is found to range very constantly from 38° to 41°. This result was obtained in Cabot Strait, and also between the Gaspé coast and Anticosti, 220 miles further in from the Atlantic, along the deep channel. This deep channel runs into the Gulf from the Atlantic basin through Cabot Strait, and maintains a continuous depth of some 200 fathoms across the middle of the Gulf to the mouth of the St. Lawrence River. It still has a depth of 100 fathoms half-way up the estuary on the Lower St. Lawrence.

Density.—It may be stated broadly that throughout the north-eastern portion of the Gulf the average surface density ranges from 1·0235 to nearly 1·0245; while in the south-western portion the density is below 1·0235, ranging usually down to 1·0220, and falling in the Gaspé Current itself to 1·0210. The dividing line between these two portions of the Gulf runs approximately from South-west Point, Anticosti, to a point in the middle of Cabot Strait. The densities in the border region near this dividing line naturally vary to some extent. The density of the north-eastern portion is practically the same as in the open Atlantic, as it was there found to range from 1·0237 to 1·0242, as shown by seven determinations made at the end of June off the south and south-east coasts of Nova Scotia.

This result is important in showing that the lower densities found in the south-western portion of the Gulf of St. Lawrence are confined to that side; and this also accords with the conclusion that the general set or drift across the Gulf is in the direction of a line from Gaspé to Cape Breton. On the other hand, the endeavour to obtain some differences locally, which would correspond with the various directions of the current, was without result; although a large number of temperatures as well as densities were taken for this purpose.

The deep water as found from samples taken at depths of 100

and 150 fathoms, both in the vicinity of Gaspé and in Cabot Strait, ranges in density from 1·0254 to 1·0261. The density of this deep water is very interesting in affording an explanation for the otherwise anomalous fact that the colder water at 50 fathoms is found to float upon it. It also corresponds with the density at similar depths, off the coast of Nova Scotia.

Current across the Gulf area.—The general connection of the Gaspé and Cape Breton currents became evident when it was ascertained that the water of lower density kept to the south-western side of the Gulf. The observations of the current in open, and the reports from steamships, also accord with a general movement of the water towards the south-east, as this is the more usual direction, and the currents which are found at times to run across this prevailing direction are to be attributed to the influence of the tides and the wind.

As to the route taken by the water in traversing the Gulf from the Gaspé region to Cape Breton, it seems fair to conclude, from the evidence furnished by the density observations, that the greater proportion finds its way eastward between the Magdalen Islands and Prince Edward Island, while a certain amount may also pass north of the Magdalen Islands, on the line from Bird Rocks to St. Paul Island. It is probable, also, that some of the water may come from Northumberland Strait, as the water there is also low in its density.

For a discussion of the probable reasons why the water of lower density keeps to the south-western side of the Gulf, the Reports of the Tidal Survey may be referred to.

The St. Lawrence River in relation to the outflow from the Gulf.—It can hardly be doubted that the low density of the water in the Gaspé Current is to be attributed to the outflow of the St. Lawrence River; and we are thus able to trace the influence of this water as far as Cape Breton, where it finally mingles with the water of the Ocean. The volume discharged by the St. Lawrence has been measured at different seasons, and with the addition of the principal tributaries along its estuary, the total volume of fresh-water discharge would probably amount in all to 340,000 cubic feet per second. This volume of fresh water will mingle with sea water for which we may assume a density of 1·0240, as this may be taken to represent either the mean density of Atlantic coast water to a moderate depth, or the density of the salter water in the Gulf itself. Under these conditions, the fresh water of the St. Lawrence would be sufficient to furnish a stream of water reduced to the lower density of 1·0230 which would be twelve miles wide and 68 feet deep, and moving with a speed of one knot per hour. This would represent the average density of the Gaspé Current, and would probably be an approximation to its average speed and its volume; and such a comparison may therefore serve to illustrate the way in which the conditions may be accounted for, if the data themselves were more closely known.

It is to be noted, however, that as regards volume the St. Lawrence River is almost insignificant as compared with the outflow of the Gaspé Current. This current, whether it flows near the coast or in the middle of the passage between Gaspé and Anticosti, has usually a width of about twelve miles. The total depth immediately off this coast is over 100 fathoms, and the depth or thickness of the current itself was ascertained from measurements of the under-current taken as far down as 30 fathoms, at times when the surface speed varied, as usual, between one and two knots. It results from these measurements that we may consider the volume of this current to be represented by a body of water 12 miles in width, with a mean depth of 30 fathoms, and moving with an average speed of 0·68 knot per hour, throughout this depth.

Such a current has a volume forty-three times greater than that of the St. Lawrence River. The volume of the Cape Breton Current, also, is probably much the same. These outflows must therefore be replaced by a return movement at the entrance to the Lower St. Lawrence, somewhere in the Anticosti region; and also by a return flow from the Ocean into the Gulf area, as the discharge of the St. Lawrence furnishes less than 3 per cent. of the amount required in either case.

The current which usually makes inwards around Cape Ray on the east side of Cabot Strait may be sufficient to compensate for the outflowing water of the Cape Breton Current; although it is also possible that the outflow from the Gulf may be partly made up for by the difference of flow in the inward direction through Belle Isle Strait, which in some years may be considerable in the early spring. This inflow at Cape Ray is in continuation of the general westward tendency of the water along the south coast of Newfoundland. The quiescence of the deep water in Cabot Strait is also to be noted in this connection.

It may be well to remark, however, that although the outflowing water of the Cape Breton Current is much warmer in the summer season than the incoming Atlantic water, it is not so at all seasons of the year. While it is probable that the total result is on the side of loss of temperature to the Gulf area, it would require extended observations throughout the year to ascertain the amount of loss and the probable effect, in consequence, upon climate in the surrounding regions.

The Current in Belle Isle Strait, in relation to the Gulf area as a whole.—On account of the tidal character of the current in Belle Isle Strait it is clear that no great volume of water can enter the Gulf of St. Lawrence from that quarter.

During the summer season the current flows in the Strait with a speed which is nearly equal in each direction; and there is only a difference in favour of inward flow to the west, which on the whole does not probably amount to more than a moderate percentage. From the discussion of all the evidence secured, it is perhaps possible that in the early spring the preponderance of inward flow may be proportionally greater than at other seasons. But no reasons have been found for supposing that this water passes completely round the west coast of Newfoundland and finds its way out into the Atlantic through Cabot Strait, between Cape North and Cape Ray, in accordance with the theory which has been more or less accepted up to the present time. All the indications are against this theory, as they show that any general current across the extent of the Gulf must lie in an entirely different direction. The reasons for this conclusion are discussed in the Tidal Survey Reports, in which the tidal character of the flow in this Strait is described and the relations of the current to the tide, the temperature of the water and the drift of icebergs are fully explained. A diagram showing the flow of the current in the two directions as observed is also given.

General Circulation in the Gulf.—In reviewing the movements of the water, with a view to tracing the general circulation in the Gulf, it is the principle of the balance of flow which is the most evident. Wherever a current of a constant character occurs, there is a corresponding return current to make up for it. Thus in Cabot Strait, the outflowing water in the Cape Breton Current is balanced by the inflow at Cape Ray; the north-eastward current on the west coast of Newfoundland is balanced by the contrary direction of the movement on the opposite shore; and we have fairly good indications of a return flow to compensate for the Gaspé Current.

It is this balance of flow which points to the nature and direction of the circulation of water in the Gulf. If we begin to trace it from Cabot Strait, where the balance between the Gulf and the Ocean takes place, the inflow at Cape Ray appears to diffuse itself more or less widely over the central part of the Gulf, but it regains its strength further north on the west coast of Newfoundland, and makes a deep bend into the north-eastern angle of the Gulf, and returns westward along the north shore. On reaching Cape Whittle it still makes westward; and, whether as an actual set or by displacing water which comes more directly from Cape Ray, it appears to work around the eastern end of Anticosti, and so compensates for the outflow of the Gaspé Current, from the estuary of the St. Lawrence. This current, after rounding the Gaspé coast, makes south-eastward as a general set or drift across the Gulf to the western side of Cabot Strait; and its waters there leave the Gulf in the outflow of the Cape Breton Current.

It also appears that the whole of the balance or compensation in the Gulf currents takes place at the surface and in ordinary under-currents, which do not probably extend to a greater depth than 50 or 60 fathoms at the most. There is nothing, therefore, to show the necessity for any appreciable movement in the deep water from 60 to 80 fathoms downward, which lies in the deep channels of the Gulf. Where direct observations have been obtained, this deep water appears to lie quiescent, without any movement that can be detected.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Prof. T. Hudson Beare, professor of mechanical engineering at University College, London, has been appointed to the Chair of Engineering in the University of Edinburgh, in succession to the late Prof. Armstrong.

Mr. J. W. Pulsford, late scholar of Sidney Sussex College, Cambridge, and second master of the Dorchester Grammar School, has been appointed a junior mathematical teacher in the Merchant Venturers' Technical College, Bristol.

Sir W. H. Preece, K.C.B., F.R.S., will distribute the prizes and certificates to the students of the South-Western Polytechnic, Chelsea, on Saturday. The laboratories will be open for the exhibition of apparatus and experiment, and short lectures will be given in the course of the evening.

The movement in favour of the establishment of a Liverpool University has received an impulse by the offer of Mr. A. L. Jones to contribute 5000*l.* towards that purpose. With the University College as a centre of activity, and the interest taken in educational matters in Liverpool, the movement ought soon to assume a practical form. At a special meeting of the council of University College, held on Tuesday, the following resolutions were adopted:—(1) That, while gratefully acknowledging the advantages which have accrued to University College, Liverpool, by its association with Victoria University, this council is of opinion that a University should be established in the city of Liverpool; that this council will welcome a scheme with this object upon an adequate basis; and that a committee be appointed to consider and report upon the whole question, with power to make inquiries and to communicate with other bodies. (2) That the committee consist of all the members of council, with power to associate with them any other persons whom they may think fit.

Sir William Hart Dyke presided at the annual meeting of the Association of Technical Institutions on Tuesday, and delivered an address, in the course of which he dealt with the necessity of a coordinated educational system, educational and industrial progress in America, the educational crisis produced by the decision as to the limitation of the powers of School Boards as regards higher grade and evening continuation schools, and the constitution of local authorities to be responsible for educational provision. Several resolutions were passed, among them being one approving the main provisions of the Secondary Education Bill, 1900, and hoping that the new Education Bill promised by the Government will prevent unnecessary and wasteful overlapping and competition between the educational work of School Boards and County Councils.

At a meeting of Convocation of the University of London, held on Friday last, a resolution was carried to the effect:—"That the life composition fees paid by the graduates in lieu of annual subscriptions to Convocation, being the capital of the University, ought not to be retained by the Treasury; and that the Senate of the University be hereby requested to represent to the Chancellor of the Exchequer that the University is the equitable owner of the same." In proposing the resolution Prof. S. P. Thompson compared the London University with other Universities as regards the support given to it. He pointed out that the University of Berlin has 5140 students and that the State subvention is more than 105,000*l.* per annum, making about 21*l.* per student. The University of Rostock, with 514 students, has a State subvention of 17,000*l.*, or about 33*l.* per student, and the annual State subvention at Strassburg amounts to 44*l.* per student. The University of Edinburgh, with 2780 students, has a Parliamentary grant of 25,870*l.*, or about 9*l.* per student; and the University of St. Andrews, with 236 students, enjoys a grant of 10,800*l.*, or 45*l.* per student per annum.

To all who are interested in the subject of education in country districts we recommend for serious consideration a small pamphlet which we have received from the Board of Education and which bears the title "Specimen Courses of Object Lessons on Common Things connected with Rural Life and Industries for all Classes in Rural Schools." It has long been recognised by educational authorities that there should be a differentiation between urban and rural education, and two years ago Sir John Gorst, in the course of a speech delivered at the Countess of Warwick's school near Dunmow, dwelt upon this necessity with his accustomed vigour of expression. Since that time the Agricultural Education Committee have been working most energetically to bring about this much-desired result, and the manifesto of the Board of Education may in some degree be looked upon as one of the practical issues of the voluntary labours of the gentlemen composing that Committee. Of course in all educational reforms in this country the usual difficulties of vested interests, inelasticity of teachers, hostility of those who fail to see the importance of nature knowledge, &c., have to be faced and, if possible, overcome. The schedules now issued should go a long way towards removing these difficulties, and it is satisfactory to learn from the introductory statement that the schemes submitted are actual examples of attempts now being made to adapt the teaching in rural schools to the requirements of country life. One paragraph, pointing out the connection of the new schemes with other studies, strikes us as being an admirable answer to those objectors who declare that the introduction of these rural subjects entails the subordination or suppression of other necessary subjects. It is shown most conclusively in this paragraph that no additional burden is imposed upon the teachers or pupils, but simply a "change in the contents of the lessons in the ordinary subjects." The Board recognise that the desired change can only be brought about gradually. It is not often that we find a Government Department actually in advance of the times, but in the present case we certainly must credit the Board of Education with having made a most important step in the right direction.

SOCIETIES AND ACADEMIES.

London.

Zoological Society, April 2.—Dr. Albert Günther, F.R.S., vice-president, in the chair.—Mr. G. P. Mudge read a paper on the myology of the tongue of parrots, and added a tentative classification of this order of birds placed upon the structure of the tongue. This memoir was the outcome of an examination of the tongues of fifty-three parrots ranging over the whole order, the Cyclopsittacidæ excepted; and the conclusion arrived at by the author was that the parrots, by the structural characters of the tongue alone, might be arranged in three families, viz. Loriidæ, Nestoridæ and Psittacidæ.—A communication was read from Prof. W. Blaxland Benham on the larynx of a rorqual whale (*Balaenoptera rostrata*) and of a cachalot of the genus *Cogia*. The paper was based upon an examination of the larynxes of specimens of these cetaceans, which had been washed up on the coast of Dunedin, New Zealand, and in it the author showed how widely different this organ was in these representatives of the Mystacoceti and the Odontoceti.—A communication from Mr. F. F. Laidlaw contained an account of the lizards collected during the "Skeat Expedition" to the Malay Peninsula in 1899-1900. Twenty-seven species were enumerated in the paper, and notes were given on their geographical distribution and habits, special attention being directed to the curious habit of *Tachydromus sexlineatus* of running about on the top of the long buffalo-grass. One new species was described, under the name *Lygosoma floweri*.—Prof. D'Arcy W. Thompson, C.B., read a paper on the pterylosis of the giant humming-bird, *Patagona gigas*.

Entomological Society, April 3.—Mr. Charles G. Barrett, vice-president, in the chair.—The Rev. A. E. Eaton sent for exhibition, on behalf of Mr. F. M. Halford a ♀ sub-imago of a species of *Ephemeridae* of the genus Ephemera, received from Central Africa, without more precise indication of locality, this being the first time this genus has been noticed from Africa.—Mr. McLachlan remarked that Ephemera usually occurred in cold alpine or temperate regions, and that the Central African example probably inhabited the mountains at a considerable altitude.—Dr. Chapman exhibited cases of *Luffia ferchaultella* from Cannes, and a spider, which are found on the same rocks, the interest of the specimens being in the fact that the spider when at rest has almost precisely the same form and coloration as the cases of the moth.—Mr. W. L. Distant communicated a paper entitled "Enumeration of the Heteroptera (Rhynchota) collected by Leonardo Fea in Burma and its Vicinity."

Manchester.

Literary and Philosophical Society, April 2.—Prof. Horace Lamb, F.R.S., president, in the chair.—Mr. W. E. Hoyle exhibited an old form of dial, bearing the name "Nathaniell Jeynes" and the date "1678," which had on one side a small circular rotating plate inscribed with the circumpolar constellations.—Mr. C. E. Stromeyer mentioned that on several occasions he had seen the sun's rays converging to a point directly opposite to the sun. In one case, when the sun was very low on the western horizon, some very marked rays, caused by a low bank of clouds, converged to a point above the eastern horizon.

—The president communicated some numerical illustrations of the diffraction of sound. These were intended to show the extreme facility with which sounds of relatively large wave-length can make their way round obstacles or through apertures. Thus, with a wave-length of 4 feet, a wire $\frac{1}{50}$ of an inch in diameter dissipates only the fraction $6 \cdot 6 \times 10^{-8}$ of the energy which falls upon it; a spherule of water $\frac{1}{1000}$ of an inch in diameter scatters only $1 \cdot 3 \times 10^{-16}$. Again, a perforated screen or grating may present hardly any obstacle to the transmission of sound, although the apertures occupy only a small proportion of the total area. Reference was made to the bearing of such results on the attempts made to improve the acoustic properties of buildings by hanging wires, and on current notions as to the possibility of the reflection of sound from clouds.

Paris.

Academy of Sciences, April 9.—M. Fouqué in the chair.—On the scientific utility of an auxiliary international language, by M. H. Sebert. This language should be capable of being used for the ordinary intercourse of social life, for commercial purposes and for scientific reports; it should be easy of acquisition, and it ought not to be an existing language. Nor can a dead language be used, even if its grammar were simplified and its vocabulary enriched. The creation of a new artificial language alone permits the realisation of simplicity and the unity of method to be obtained by the union of elements borrowed from different living tongues.—On the services which the auxiliary international language of M. le Dr. Zamenhof, known under the name of *Esperanto*, can render to science, by M. Ch. Méray.—Generalisation of Trouton's law, by M. de Forcrand. In all chemical or physical phenomena the heat of solidification of any gas is proportional to its temperature of vaporisation under atmospheric pressure.—New method of distinguishing colouring matters, application to the indophenols, by MM. C. Camichel and P. Bayrac. The absorption of light by solutions of indophenols in alcohol, ether, carbon bisulphide and chloroform has been studied. Taking wave-lengths as abscissæ and coefficients of transmission as ordinates, curves of the form of the parabola were obtained with the convex side towards the axis of abscissæ; the branch of the curve corresponding to the red rises much more rapidly than that corresponding to the green or blue. To distinguish each of the compounds studied, the lowest point of the curve was determined—that is, the minimum transparency. This minimum is independent of the concentration for all the compounds of which the coefficient of absorption is proportional to the concentration, following Beer's law; it varies with the solvent in a manner different from that noticed by Kundt.—On the reaction of the amidobenzophenones and the aromatic amines in the presence of sulphuric acid, by M. Paul Lemoult. In the presence of sulphuric acid the paramidobenzophenones give with certain aromatic amines, to the exclusion of others, reaction products which are colouring matters; the only amines capable of this reaction are those which have at least two aromatic groups directly united with nitrogen; it is necessary, moreover, that one of these be a phenyl group, and that its para-position be free, the nitrogen being in 1.—The angle limiting the numeration of objects and the movements of the eyes, by MM. André Broca and D. Sulzer.—Is the resistance of Algerian sheep to foot-rot hereditary? by M. P. Pourquier.—On Koswite, a new pyroxenite from the Ural Mountains, by MM. L. Duparc and F. Pearce.—On the "blood rain" observed at Palermo in the night of the 9th to 10th March, 1901, by M. Stanislas Meunier. In a hundred parts of the powder were found, water, 5·20; organic matter, 3·17; sand, 59·14; carbonate of lime, 23·91; and (by difference) clay, 8·58.—On the oxidation of iron protosulphide, by M. Gay-Lancermin.

KORSCHELT AND HEIDER'S EMBRYOLOGY.

Text-Book of the Embryology of Invertebrates. By Profs. Korschelt and Heider. Translated by M. Bernard. Vol. ii., 1899 (pp. xv+375); Vol. iii., 1899 (pp. xii + 441); Vol. iv., 1900 (pp. xi+594). (London: Swan Sonnenschein and Co., Ltd.)

WE welcome with great satisfaction the publication of Parts ii., iii. and iv. of this important work. Originally issued in German in three parts, the first two of which were reviewed in these columns in 1891 (vol. xlv. p. 145), the English translation was issued in four parts, the first of which was published in 1896, the second and third in 1899, and the fourth part in 1900. In the somewhat considerable interval which has elapsed between the issue of the original work and that of its English translation, extensive additions have been made to our knowledge in several departments of embryology. These have been met by editorial footnotes and supplementary lists of literature. The latter appear to have been carefully compiled and will be found by students to have great utility. Indeed, it may be said that, so far as the literature is concerned, Parts ii., iii. and iv. are up to date, and there can be no question that they will be of the greatest value to English zoologists. All that was said in praise of the work in the review of Part i. (NATURE, 1896, vol. liii. p. 361) applies with almost greater force to the volumes before us. They constitute an accurate and comprehensive treatise on invertebrate embryology, and no zoologist's library can be considered complete without them.

The work of the translator and editor also appears to us to have been excellently carried out. The style is clear and the work in its English form is eminently readable. We congratulate the editor upon his sensible decision to translate the German word "anlage" by its English equivalent, "rudiment," and we entirely agree with his remarks in the preface to Part i. on the subject. In opposition to him, however, we think that his restoration of the word "rudiment" to its proper use in embryology will satisfy, if not all zoologists, at least all intelligent zoologists. The word has no biological application outside embryology. In embryos alone can we actually see the first rough outline gradually shaping itself into the perfect organ; and there can be no question that we are dealing with a rudiment. But the same cannot be said when the word is applied to organs of the adult. These undergo no change, except retrogressive changes; and to apply the word "rudimentary" to them implies the possession of prophetic power. We mean, if we apply the word "rudimentary" to an adult organ, that in some remote descendant of the animal under consideration the organ will become more perfect as the result of evolutionary change. This is an entirely gratuitous assumption, which we have no right seriously to make. The word "vestige," the use of which our editor also discusses, is on a very similar footing. It may be appropriately applied to organs which undergo regression, after having attained a more perfect structure in the earlier phases of growth, but do not totally disappear; but it cannot legitimately be applied to adult organs on any other condition. For to call an adult organ, which has not undergone such regression, "vestigial," implies a knowledge of the past, which we have not got, just as rudiment, when applied to adults, implies a knowledge of the future. It may be that the small and imperfect muscles of the outer ear of man are vestiges of more perfectly developed muscles in a remote ancestor, but we have no knowledge that they are so; this view of them is a mere presumption, based on no fact whatsoever. To apply the word "vestigial" (unless the above-mentioned condition be satisfied) or "rudimentary" to adult organs is merely to beg the question at issue, and we require another word to apply to organs which we may feel tempted to designate in that manner. The same remark applies to those organs of the embryo like the neurenteric canal or gill slits of vertebrata, which make their appearance in development but give rise to no structures in the later stages or adult.

As a general rule in German works, the treatment of cœlom and body-cavity is not up to date. Our authors, we are glad to see, are not open to serious blame in this respect, but they have not been able entirely to shake themselves free of traditional conceptions with regard to these structures. They constantly make use of the words pseudococle, primary body-cavity, secondary body-cavity, which all belong to a past epoch of morphology; and they sometimes use language which might lead the reader to suppose that they do not distinguish clearly between hæmocœle and cœlom (iii. 90). Moreover, in dealing with cases in which the nephridia are actually transformations of the cœlom in the ontogeny, they speak of them as though they were really only secondarily related to it (iii. 205). But, in spite of this, it must be admitted that their ideas on these subjects are more advanced than has been usual with German authors.

As was stated in the review of Part i. of this work, the standpoint of our authors is that of the seventies and early eighties of last century. This is clearly seen in their discussions on ancestral derivation, in their chapters on general considerations (which, in our opinion, are too long and often somewhat tedious); in their treatment of the layer-theory, in spite of such statements as those given on p. 301 of Part iv., by which it is shown that the central nervous system arises from ectodermal rudiments which also give rise to mesoderm; in their frequent inability to accept observations which depart at all from traditional conceptions, as witness their treatment, on pp. 166 and 169 of Part iii., of Sedgwick's observations on the cleavage and derivation of the enteron of *Peripatus capensis*. We do not make these remarks in any way to detract from the merit of our authors' work. Morphology is at present in a transition state, and naturalists do not readily part with the old hopes and beliefs which fired them with so much enthusiasm in the early Darwinian days and spurred them on to make those comprehensive researches of which this book is such a worthy record.

CHEMISTRY FROM HARVARD.

Elementary Studies in Chemistry. By Joseph Torrey junr., Instructor in Harvard University. Pp. viii+487. (Westminster: Archibald Constable and Co., Ltd. 1900.)

THIS book is written with an evident desire to present elementary chemistry in such a way as to give full effect to its educational capabilities without neglecting other ends and without a sacrifice of those external features of interest which in the past have covered such a multitude of sins. Mr. Torrey has, in fact, had but one aim, and that to make the best of his subject. A spirit of entire forgetfulness of examiners and syllabuses pervades the work, and things and theories are dealt with according to their intrinsic importance. To say so much is to say a great deal in favour of the book, and to this it must yet be added that the author writes like a practised and enlightened teacher. English teachers of chemistry, both in secondary schools and colleges, will do well to look at Mr. Torrey's book, if only to see the sort of thing that is put forward from Harvard as a suitable course of elementary chemistry. It must be remarked, however, that the course is not intended for quite the same class of pupil that in this country has in recent years been supplied with reformed courses of elementary science. Mr. Torrey's course seems intended for the later stages of the secondary school or for beginners in a college.

To point out the essential difference of plan between teaching chemistry in a stimulating way and teaching it in a deadening way would be to repeat what has often been said before in these columns. It is becoming the habit to summarise these two plans in the words heuristic and didactic, and these philosophical terms have acquired something of the character of verbal missiles, to be hurled by contending parties as weapons of offence.

Two main contentions are heard against the feasibility of improved methods of science teaching. The first is to the effect that a certain proportion of youth have a natural repugnance to science, even in its most inviting form. They refuse to be interested, they will not find out; therefore they must be told things and made to listen and repeat. It seems very doubtful whether this allegation does not very frequently arise from an injudicious or a too impatient teacher, or from one who has the misfortune to deal with good material already spoiled by bad treatment. Where it is wholly true the reply would be, let such pupils be tried with some other subject. If the same resistance continues to be shown, we surely are dealing with something akin to the deficient or feeble-minded class for which at last some separate treatment must be provided. It seems an unfortunate conclusion to reach, that because a good method does not appeal to all, it should be alloyed with an inferior one for the sake of a few.

The second contention is that a good course of science teaching presents difficulties from the examinational standpoint. This is, unfortunately, only too true. It is, undoubtedly, a great practical obstacle, and its removal can only be looked for when further abatement has taken place in the rigour of the whole examinational system, which holds so many good teachers of all subjects in its paralysing grasp.

It is difficult to give in narrow limits an indication of the sequence and style of Mr. Torrey's course. The book is written in the form of short lectures of a suggestive kind, followed by indications of the laboratory work to be done in connection with, or consequent upon, the lectures. It begins with physical topics, including certain measurements, thermometry, vapour pressure and density of gases. The chemistry begins with hydrogen and the composition of water, which is to be studied quantitatively; the composition of hydrogen chloride is then dealt with, in order to accumulate enough material for a discussion of Avogadro's theory. Then follow oxidation, symbols and formulæ, determination of atomic weights, acids, bases and salts, electrolysis and electrolytic dissociation, sodium as a metallic element and its chief compounds, the sodium group of metals, the atmosphere, ammonia, nitric acid, the nitrogen family, the sulphur family, the calcium group, &c., ending with carbon and its inorganic compounds. In an appendix we find hints on the manipulation of glass, a list of apparatus required, a list of books for a teacher's library, a few numerical tables and two pages of logarithms.

It would not be difficult to find fault with the order of topics, and the chief objection would perhaps be to the early introduction of the theory of atoms and molecules and other theoretical matters. Mr. Torrey's order is probably not so good as some which have been elaborated in this country, but the method of the book in detail is so good that some faults of arrangement may be allowed to pass, and besides this it must be remembered that the book is not intended for children.

It is possible that on working through the book some faults of detail would be discovered. Many of the experiments described are novel in form, and some seem hardly likely to succeed. For example, on p. 98 an experiment is described, in which manganese dioxide is to be heated in a tube containing hydrogen chloride. The shrinkage of volume on opening the tube below a saturated solution of brine is said to represent the hydrogen which has disappeared. This is obviously wrong, and, practically speaking, the experiment is altogether an undesirable one.

In conclusion, it may be remarked that the book is unusually free from words or pedantries peculiar to America. An exception to this statement occurs on p. 7, where there is a reference to "the graduate being held in front of a dark surface to make the lines show more clearly." The graduate there means a glass vessel and not the careworn teacher. A. SMITHELLS.

A NEW EDITION OF WHITE'S "SELBORNE."

The Natural History and Antiquities of Selborne, and a Garden Kalendar. By the Rev. Gilbert White, M.A. Edited by R. Bowdler Sharpe, LL.D. Two vols. (London: S. T. Freemantle, 1900.)

IT will be as well to state exactly what is contained in these handsome but rather bulky volumes; the price is high (3*l.*), and purchasers will be glad to know what they are buying. In the first volume are the letters to

Pennant, *i.e.* the first part of the "Natural History of Selborne," freely interpolated with bracketed addenda from the originals in the British Museum, and including three or four letters of which White did not make use in preparing his book for the press. Then, pleasantly introduced by Dean Hole, and occupying more than 200 pages, come White's garden diaries from 1751 to 1771; of which a specimen, and enough to give an idea of White's personal activity as a gardener, was printed as an appendix to Bell's edition of the "Selborne" in 1877. The second volume contains the letters to Barrington, also with additions and interpolations from the originals, except in the case of the famous "monographies" of the Hirundinidæ, which were published separately by White in the *Philosophical Transactions*; the antiquities of Selborne are also here, and at the end we find a bibliography and a useful index, which appear to be sufficiently complete. Each volume is profusely illustrated. Mr. Keulemanns' drawings of birds are familiar and welcome; we have also a large number of fancy sketches by Mr. E. Sullivan, in most of which an imaginary Gilbert White is a prominent figure. Mr. Herbert Railton's head- and tail-pieces are, for the most part, delicate and attractive. As regards the notes, Dr. Sharpe's name is, of course, a sufficient guaıantee of the soundness of those on birds, and the only fault to be found with them is that they are occasionally a little wanting in succinctness and self-repression. Several of Dr. Sharpe's colleagues at the British Museum have provided him with useful notes relating to their departments of natural history, and a judicious selection has been made from the notes of previous editors, especially Bell and Harting.

From what has been said above, it will be seen that this is not really an edition of the book that White so carefully wrought into an artistic form, and that we all know and love. It is not pleasant to say it, but said it must be emphatically, that the liberties here taken with White's work have absolutely no literary justification, and have robbed it of much of that peculiar charm which, as Prof. Newton has well said in his admirable article on White in the "Dictionary of Biography," it is impossible to explain in words. What would have been White's own feelings if he had been forced to see in print the very portions of his letters which, with his own good sense and the respect of his age for publication, he had deliberately cut out, and the insertion of two hundred pages of his gardening notes between the letters to Pennant and those to Barrington? If it be argued that (as Dr. Sharpe seems to think) we learn something new about White himself by getting an idea of the original form of his letters and of the way in which he wrought his book out of them, the plain answer is that we already know all that is essential about him, and that one thing we know for certain is that he had a sense of literary form which has made his book immortal, and which should have secured for it more reverential handling than is to be found in these volumes. It might, indeed, be possibly justifiable to print the whole of the original letters as they left his hand; but not as an edition of the "Natural History of Selborne," which should always be allowed to stand exactly as his genius designed it. It will be the duty of future editors to see that none of the passages now interpolated are allowed to creep permanently into the text of the original work.

Dr. Sharpe's enthusiasm for his author is unquestionable, as may be seen from his brief but pleasant introduction to the first volume; so, too, is the labour that he has spent on his editorial task. But the perils of the editor of a classic are great, and enthusiasm alone will not teach him how to avoid them.

OUR BOOK SHELF.

The Romance of the Heavens. By A. W. Bickerton. Pp. 284. (London: Swan Sonnenschein and Co., Ltd., 1901.) 5*s.*

THE theory of constructive impact, of which a popular account is given in the present book, appears to have had its origin in an attempt to explain the phenomena of new stars by the grazing collision of two dark bodies. Hitherto the theory has not been hospitably received by astronomers, and the more elaborate exposition now presented will probably meet no better fate. The truth seems to be that in spite of his claim to have discovered numerous facts not known to "ordinary" astronomers, the author lacks familiarity with spectroscopic work and astronomical methods generally. He quite condemns himself by suggesting (p. 235) that more confirmatory evidence in the case of Nova Aurigæ was only wanting because astronomers, unguided by the theory, did not make "more liberal and careful observation." As a matter of fact, the most valuable records were photographic, and are still as much in evidence as during the visibility of the Nova, and the observations certainly cannot be interpreted as indicating the presence of three bodies of the kind required by the theory. The theory thus breaks down at the outset, and it would not be difficult to show the weakness of most of the "overwhelming" astronomical evidence on which depends its extension into collisions of nebulæ, clusters and cosmic systems by which it is argued that the existing forms and distribution of celestial bodies are completely explained. The merest possibilities are frequently magnified into certainties, as, for example, the occurrence of variable stars in pairs, and the preponderance of variability in double stars.

The resources of the theory appear to be unlimited. While one collision produces a new star, another results in a star cluster, another blows a planet into asteroids, and still another disperses a satellite into a ring such as that of Saturn.

We have not examined all the calculations which are given, but we may point out that the results arrived at for the separation of two stars of assumed distance and velocity (p. 58) are in each case six times too great.

The book is admirably written and is by no means without interest; but readers should be warned against mistaking the author's assertions for demonstrated truths.

Les Diastases et leurs Applications. By E. Pozzi-Escot Pp. 218. (Paris: Masson and Co., 1900.)

THIS little volume forms one of the series of Aide-Mémoire, some of which have been previously reviewed in this journal. Its modest preface disarms criticism. "Le lecteur ne devra pas chercher ici l'exposé de théories nouvelles; nous nous sommes contenté d'exposer les faits connus, de les relier l'un à l'autre et d'en tirer chaque fois qu'il y a eu lieu des conclusions légitimes." And further, "Forcément incomplet, nous espérons que notre travail (qui n'est point fait pour des biologistes, mais bien pour une collection destinée aux ingénieurs et aux chimistes), rendra néanmoins quelques services et

facilitera la diffusion de la notion des actions diastasiques, dans le domaine pratique."

The author fulfils the promise of his preface in giving a clear though brief exposition of the action of enzymes or *diastases*, special attention being directed to the experimental methods employed in the study of this subject and in their application to the brewery and the distillery.

The errors in spelling are numerous, and should be revised in a subsequent edition. Schunck appears as Schmuk; Marshall Ward figures as two persons, Marshall and Word; Croft Hill's individuality is also lost as Crop and Hill; O'Sullivan loses the O' and Lindner is spelt Linter, whilst the English name Heron and the German, Geduld, are converted into the French Héron and Gédulte.

Erythrozyme is written erythrozine, racemosus is spelt raciniosus, penicillium appears as penicellium and octosporus as octopodus.

An index would be a valuable addition. J. B. C.

Mongolia and the Mongols: Results of an Expedition to Mongolia in the Years 1892 *and* 1893. By A. Pozdnéeff. Vol. ii. 8vo. Pp. 516. Numerous photo-engravings (Russian, 1900).

THIS is the second of a series of volumes on Mongolia and its inhabitants which are being prepared by Dr. A. Pozdnéeff, and it contains the traveller's diaries during the second year of his journey, when South-eastern and Eastern Mongolia were visited. Starting from Pekin, Dr. Pozdnéeff went to Kalgan—the centre and depot for Russian trade with China—and thence to Kuku-khoto, or Gui-hua-chen, the next important commercial centre of Southern Mongolia. Returning to Kalgan, he visited that portion of Mongolia which lies on the eastern slopes of the Great Khingan—namely, the towns Fen-nin-sian and Zhe-ho, or Chen-de-fu, whence he went to Dolon-nor (Lama-miao). All these places are well known long since, but, speaking currently Mongolian, Dr. Pozdnéeff has learned much more about the trade in these towns than other travellers had before him, and having, moreover, in his capacity of learned Mongolist a free access to the Lamaite monasteries, he was enabled to collect a great amount of information about the inner life of Mongolia, various questions of worship, and especially about the antiquities preserved in the monasteries. Proceeding from Dolon-nor northwards and north-westwards, towards the Kerulen River, he visited the ruins of Kai-pin-fu—the thirteenth century capital of Khubilai-khan—and obtained there full casts and photographs of an interesting inscription dating from the fourteenth century. Another very interesting Tibetan and Mongolian inscription, dating from 1626, was copied in the same way at Tsagan-suburga, on the Shara-muren River. It may now be taken that this much-controversed spot was one of the five Lao or Kidan capitals—Lin-han-fu.

The remarks of the diary on the way across the Gobi are especially interesting, in that they give the exact limits between the Gobi proper and the zone of land which lies on the western slopes of the Great Khingan. This limit corresponds with a line which may be drawn on the Russian General Staff Map through the spots where the rivers shown on this map as flowing from the Khingan end in small lakes or marshes as they enter the Gobi. M. Pozdnéeff, who crossed the Gobi in June, fully confirms the view upon this region which begins now to prevail, namely, that it is not a desert, but a dry, rolling prairie. In fact, it has the same physical aspects as the dry "rolling prairies" of Canada at the approach of the Rocky Mountains.

The volume gains very much from the excellent photo-engravings with which it is illustrated. They give a good idea of the physical characters of these portions of Mongolia. P. K.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Gothic Vestiges in Central Asia.

I AM in thorough accord with the main principles indicated in Dr. A. C. Haddon's communication, which appeared in NATURE, vol. lxiii. p. 309 (January 24), more especially as to the eastern extension of a fair dolichocephalic race or races, at least as far east as the north-western frontiers of China. It has, however, always struck me, as a student of the ethnology of these districts, that sufficient attention has not been given to the geographical changes that have certainly occurred throughout the whole of Central Asia, and without which it appears impossible to understand such writers as Herodotus, Arrian and Ammianus Marcellinus. I claim no new discovery in suggesting, with Colonel Tchaikofsky (quoted by Schuyler, vol. i. p. 53), that during the Classical period the rivers Chu and Sary-su, instead of losing their waters in desert lakes, united at Perovsky with the Jaxartes, and flowed along the deserted bed, now known as the Jany Darya, joining finally the old Oxus and making their way along what is still known as the "Ancient Bed" of the Amu Darya to the Caspian. We thus arrive at a satisfactory explanation of the crossing of the "Araxes" by Cyrus, and his description of the homeland of the Massagetæ, whom we are then justified in associating ethnologically with the Getæ or Goths of other authors. This would throw light also on the position of Arrian's Alexandria Eschate, which I would identify with the modern Jizakh. This was situated on the Tanais, which seems to have been an overflow channel of the upper Jaxartes, leaving the main river at the bend below Khojend and flowing past Jizakh into the Taz Khane, whence it found its way into the Jany Darya.

We thus also get a satisfactory position for the Issedones, also a Gothic tribe ("West-Saetons"), east of whom were the Asii, Asiani or Pasiani, the Wusuns of the Chinese, who are described as "having blue (or green[1]) eyes, red beards and monkey-like faces"—alluding to their faces covered with tawny hair.

When, however, Dr. Haddon comes to his Chinese authorities several inaccuracies appear in his account. As Dr. Haddon himself is, apparently, not a student of that language, he has naturally been dependent on others, and the second-hand information with which he has been supplied is in the last degree misleading. He speaks, for instance, of the "Ssé or Sek (who are identified with the Sacæ)." I have a fair first-hand acquaintance with the older Chinese writers, and find myself unable to place these tribes. There were, at the period of which he speaks, Shuks, or rather Pa-shuks, in Szechwen; but there is no reason to connect them with any external tribe, nor have we a suggestion that they have ever migrated. There was a country—not a people—called Su-li, but the phonetic element here is Sulak, and we must identify the district with the Surak of the Bundahîsh, the country about the lower Jaxartes. The later writers, it is true, talk of a kingdom—not a people—called by Matwanlin Sse; but it is, apparently, the modern Sarakhs. The classical Sacæ, Scyths and Dahæ seem to be variations of the one word, and may be connected with the Tochari of Strabo the Tahia of the Chinese. I am, however, doubtful of Scyth or Sacæ being used by the Greeks in any sense as an ethnographic term; rather it applies to their stage of civilisation. We learn very little of these Tokhars from Chinese sources, but from Strabo we gather that they, in conjunction with the Wusuns and the Sakarauli (possibly the inhabitants of the Sarik-kol Pamir), bore down on Bactria and put an end to the Greek line of kings. About the same time the Yueh-ti, driven from their homes by the Hiung Nu (Turks), arrived in the country, and the two peoples seem to have more or less coalesced, and we find them a few years later living in apparent harmony, but occupying each its own side of the Oxus, the Yueh-ti apparently being the predominant race, or at least supplying the royal race. This is very different from the account given by his supposed authorities to Dr. Haddon. I have had the misfortune to have met with M. Drouin before, but now become acquainted with

[1] T'sing, the word used, means the colour of deep, pure water—grey, blue or green.

M. Ujfalvy for the first time. Apparently these authors have gathered their ideas from the French writers of the last century, whose knowledge of Chinese was confined to such works as the *B'ungkien Kangmu*, or even later works of about as much authority as Rollin's "Universal History."

A good deal of interest attaches to the Yueh-ti. Their original name was possibly Viddhal, and they seem to have had some prehistoric connection with the Yâdavas, who took part in the Indian immigration. There never was any doubt about their being the same people afterwards known to Greeks and Arabs as Ephthalitæ and Haithals respectively. With the Yueh-ti were associated in ancient Chinese legend the Mats, or Mat-su, apparently Maddhals, as in Indian lore Maddhu is associated with the Yâdavas, and this brings us to the later branch of the Yueh-ti, who in these authors by a strange mistake are called Yetha. Really the name in modern Chinese is Yenta, a very different sound. In the old language it was I'm-dat. Where the first syllable appears frequently doing duty as merely the initial *m*, Da, or rather Dat, where final *t* represents *l*, stands, then for Maddhal. This subtribe seems about the fifth century to have been settled in the neighbourhood of Bamian, and, except that it was less civilised than the other branches of the family, to have had little to distinguish it.

Both Greek and Chinese authors concur in describing these Ephthalites as being distinctly blond, with full beards, of a handsome type, and of lively manners. Menander calls the king under whose guidance they crossed the Hindukush Catulphus, at whose Teutonic aspect Colonel Yule expresses surprise. The Chinese, however, name him Kitolo, evidently the same word; most Chinese names consisting of only three words, the remainder is generally omitted in the transliteration of foreign names. Catulphus is, however, evidently the nearest Greek equivalent for Gothic Caedwulf. These allied peoples went amongst the Indians by the common appellation of Hunas, whence the alternative Greek name of White Huns, which has no connection whatever with that of the European Huns of the fourth century, whose swarthy complexions and hairless faces indicate a very different origin. These apparent Gothic connections are not confined to the Ephthalites, but occur throughout, the leader of the Scythians, ἐκ τῆς 'Ασίας, *i.e.* Wusuns, whom Alexander defeated outside Kyropolis, was, according to Arrian Satrakes, the Greek equivalent for Gothic Sietrich.

Of Dr. Haddon's Hoa, evidently derived from some mistaken French transliteration, I cannot even guess the origin. There is no such name to be found in the earlier and more authentic Chinese writers. Dr. Haddon is, however, quite correct in identifying the modern Chinese Yuan yoan, or Jwan Jwan, with the Avars of Gibbon.

Dr. Haddon expresses some surprise at the beardless faces of the later Huna kings; from the appearance of the king depicted on the coin, and its overhanging brows and prominent nose, he certainly did not belong to the smooth-faced races of the extreme north and east of Asia. So we may be sure that the bareness was artificial; it was probably the fashion of the time to shave.

With regard to the type of face and skull represented on the coin of Jayatu Mihirakula, I may remark that I met last night at dinner a gentleman of whom it might be called a portrait. I may describe him almost in Dr. Haddon's words as: Nose large, jaw powerful, neck fleshy, the occipital region of the head deficient, the vertex produced into a truncated cone. This remarkable shape was in his case quite natural. Moreover, with the exception of a moustache his face, as in the coin, was hairless. He had similar overhanging eyebrows, a like marked notch at the bridge of the nose, and an almost identically aquiline nose. His eyes, however, were not oblique, nor had he the slightest trace of the "Tatar," nor did he in any way approach the "Mongolian" type. The gentleman is, in fact, a Parsee of the highest type, polished and affable.

Shanghai, China, March 13. THOS. W. KINGSMILL.

Graphic Solution of the Cubics.

THE note by Mr. T. Hayashi, published in NATURE of March 28, suggests to me the following little historical remark. The method given by Mr. Hayashi for the cubics is due to Monge, "Correspondance sur l'École impériale polytechnique," par M. Hachette, vol. iii. p. 201; "Solution graphique de l'équation du troisième degré, $x^3-px+q=o$," par M. Monge.

"L'équation proposée résulte de l'élimination de y entre les deux $y=x^3$, $y=px+q$; l'une est le parabole cubique, . . . l'autre répresente une droite. . . . Ayant construit ces deux lignes, les abscisses x des points où elles se coupent, sont evidemment les racines de l'équation proposée."

Monge gives also a practical construction of the curve on a small sheet of paper *Nil sub sole novi!* G. VACCA.

Via Bogino, 4, Torino (Italy).

THE WORK OF THE NATIONAL ANTARCTIC EXPEDITION.

THE final programme of the scientific work of the National Antarctic Expedition had not been arranged at the date of my departure from England, as the Joint Committee of the Royal Society and the Royal Geographical Society had not issued its full instructions as to the route and plan to be adopted. A provisional summary may, however, be useful by calling forth suggestions while there is yet time to use them.

FIELD OF OPERATIONS.

It is, perhaps, hardly necessary to remark that it is not the object of the expedition to reach the South Pole, but to investigate the Antarctic regions; and though some of the problems cannot be solved unless the existing southern record is broken, the expedition is not being equipped especially for the attainment of much higher latitudes than have already been reached. Had that been one of the main objects of the expedition, either the ship might have been sent southward on a different line, or the expedition would have been provided with greater sledge-hauling power.

The operations of the British expedition are restricted to the half of the Antarctic area east of the meridians of 90° E. and 90° W., *i.e.* to the region south of Australia and the Pacific. The western half, including the region south of America, the Atlantic and Africa, is to be explored simultaneously by the German expedition under Prof. von Drygalski, by a Swedish expedition under Dr. O. Nordenskjold, and, it is hoped, also by a Scotch expedition under Mr. W. S. Bruce. This division of the field of work between the British and German expeditions was proposed at the Geographical Congress at Berlin, and has now been accepted on both sides and the plan of work arranged accordingly. So far as can be judged with our present knowledge, this plan, other things being equal, gives the German expedition the chance of the most striking geographical discoveries and the British expedition the opportunities for a richer harvest of scientific results.

The scientific work of the expedition is directed to cover as wide a field of research as is consistent with the essential objects of the expedition. Of these the object of primary importance is the study of terrestrial magnetism. It was upon the need for work upon this subject that the appeal to the Treasury for funds was based, and it was to enable the magnetic observations to be properly made that it was thought advisable to provide a new ship rather than adopt the less expensive course of adapting an existing whaler. A new ship—the *Discovery*—has accordingly been built by the Dundee Shipbuilding Co. She is a modified whaler of somewhat more than 1500 tons displacement, and with engines of 450 horse power.

The staff of the expedition is as follows:—The executive staff consists of Commander R. F. Scott, R.N., commander of the expedition; Lieutenant Albert Armitage, R.N.R., who distinguished himself in the Jackson-Harmsworth expedition to Franz-Josef Land, second in command and navigator; Lieutenants Royds, Barne and Shackleton; and Mr. Skelton, engineer. The civilian staff consists of Mr. T. V. Hodgson, formerly of the Plymouth Biological Laboratory and curator of the Plymouth Museum, biologist; Dr. R. Koettlitz, botanist; Mr.

Wm. Shackleton, of the Solar Physics Laboratory, physicist and astronomer; Dr. E. A. Wilson, zoologist and doctor to the land party; and the writer, who is director of the civilian staff and in command of the operations on shore. It is hoped that it may be possible to arrange for additional scientific assistance from volunteers who will accompany the ship in her cruises from Melbourne. Mr. G. Murray, F.R.S., who is editing the "Antarctic Manual," has kindly consented to act as deputy director of the civilian staff, and will superintend the scientific equipment in England, and probably accompany the *Discovery* as far as Melbourne.

Terrestrial Magnetism.

Considerations for the magnetic work have exercised a dominant influence in the plan of operations ordered by the Joint Committee. Magnetic work in the British field of operations has difficulties from which work in the western half of the Antarctic area is free; the horizontal magnetic force is exceptionally low, and great decimal variations in declination are frequent. These variations will, of course, affect the observations made on the *Discovery*, and unless this factor can be allowed for, it will be impossible to determine the proper magnetic elements for the ship's points of observation. Accordingly, the Magnetic Committee has declared it essential that there should be a station on shore in Southern Victoria Land to act as secondary magnetic base. It will be the first duty of the party landed at this station to secure a continuous magnetic record for a period of twelve months. For that purpose it will be supplied with a magnetograph, which will be under the special care of Mr. Shackleton; should the recording instrument fail, personal observations must be taken as frequently as possible. The records at this station will enable the observations taken during the magnetic survey at sea to be corrected for diurnal changes.

The Joint Committee has, therefore, decided that the *Discovery* shall proceed from her southern headquarters at Melbourne to Southern Victoria Land, where Captain Scott will land a party somewhere between McMurdo Bay and Wood Bay. The land party will consist of eight men, including Mr. Shackleton as physicist and Dr. E. A. Wilson as doctor and zoologist.

The Geographical Problems.

The selection of Southern Victoria Land, and the neighbourhood of Mounts Erebus and Terror, for the site of the land station is recommended by geographical as well as by magnetic considerations. Topographical exploration is the second important branch of the work of the expedition, for it is necessary as a base for much of the other work; and it was probably interest in this subject that inspired Colonel Longstaff's munificent donation, which brought the expedition within the range of practical politics.

Fortunately, sufficient is now known of the geography of the eastern half of the Antarctic area to enable a definite plan of operations to be arranged. We need not, like Cook, strike blindly into the Antarctic, knowing no more of one line than of another. There are two main geographical problems in the British field of work. The first problem is whether the known lands to the south of Australia—Victoria Land, Wilkes Land, Adelie Land, Geikie Land, Newnes Land, Termination Land, &c.—are all part of one great continent or are members of an Antarctic archipelago. The classical and mediæval geographers accepted the existence of an Antarctic continent, belief in which is now supported by Suess's principles of geographical distribution.

Australia, as Suess has explained to us, consists of a great plateau bounded to the north and east by the important tectonic line which passes through New Guinea, New Caledonia and New Zealand. Ritter has therefore very plausibly suggested that the volcanic chain that forms the eastern face of Victoria Land is the continuation of the New Zealand volcanic line, and that the coast of Wilkes Land is a southern extension of the Australian plateau.

This hypothesis, advanced at first on general considerations, is consistent with all available geological evidence. The specimens collected by Wilkes and the boulders dredged by the *Challenger* and the *Valdivia* include archæan and sedimentary rocks similar to those of Southern Australia; and Mr. Borchgrevink has brought home a collection of specimens which have been kindly shown to me by Mr. Prior, and are practically identical with some of the Lower Palæozoic rocks of Victoria.

The rocks of the eastern face of Victoria Land have been described by Teall and David; and their identifications show that the volcanic rocks resemble those of New Zealand.[1]

There is, therefore, little doubt that Antarctica is *geologically* a continent, consisting of a western plateau, composed of archæan and sedimentary rocks like those of Australia, and of an eastern volcanic chain. But whether Antarctica is still a continent *geographically* is less certain; and this question can only be conclusively settled by a survey. Land journeys westward and southward from Mount Erebus ought to settle this problem.

The volcanic line of Victoria Land runs north and south for some 8 or 10 degrees of latitude; at 77° S. lat. the coast and the volcanic chain bends abruptly to the east. The discovery of their eastward continuation is the second main geographical problem to be settled in the British half of the Antarctic area.

Ross sailed to the east for some 30 degrees, along the face of the "Ice-Barrier"; and though the origin of the barrier-ice is not yet certainly known, it has probably been formed on land. Ross has recorded a "strong appearance of land" beyond the eastern end of the barrier (160° W.), and the barrier may be roughly parallel to the edge of a land line connecting the Parry Mountains and Ross's "apparent land."

Beyond this point is a gap until, 70° further to the east, we come to Graham's Land. In the intermediate area there has been no direct record of any large land area that would connect Graham's Land and Victoria Land. But Cook's description of his view from his turning-point at 137° W. 67° S. is suggestive of a land with peaks rising through an ice-sheet rather than of a number of icebergs frozen into pack-ice. Cook, however, clearly interpreted it as the latter. The indirect evidence as to the geographical character of the line between Graham's Land and Mounts Erebus and Terror is more important. It is based on Suess's law of coast distribution.

The Pacific Ocean is bounded by coasts the trend of which is determined by mountain ranges which run parallel to the shore. This rule holds in Eastern Australia, Eastern Asia, Malaysia, and throughout the western coast of America with an unimportant exception in Central America. The remaining coasts of the world are on the Atlantic type, in which the coast lines are not determined by the trend of long, folded mountain chains; the mountain ranges are cut transversely or obliquely, and the coasts are mainly formed of plateaux and coast plains. Ritter has made the probable suggestion that the low coast of Wilkes Land is on the Atlantic type, and the high mountain chain of Victoria Land is on the Pacific type. Graham's Land has a characteristic Pacific coast; and when we remember the persistence of that type round the whole of the

[1] The continuation of the tectonic line that crosses Southern New Zealand obliquely to the main New Zealand line has not yet been determined, and it may be found to play an important part in the southern shore of the Pacific.

known shores of the Pacific, it appears not improbable that the Southern Pacific is bounded by a coast of the same type. If so, we should expect the Parry Mountains and Graham's Land to be connected by a series of mountain bows, the curves convex to the north, and with at least the traces of island festoons.

In that case the great tectonic lines which bound the Pacific to east and west are connected across the Antarctic area; and if that can be proved the unity of the great Pacific depression will be completely established.

That this South Pacific coast line can be discovered and surveyed by the expedition is improbable; when we remember the limited extent of the areas explored by Arctic expeditions, one ship cannot be expected to investigate half the Antarctic zone in the course of sixteen or eighteen months.

Considerable indirect evidence bearing on this problem may, however, be obtained; information as to the geology of Dougherty Island, and an extensive collection of bottom deposits along the edge of the ice-pack in the Southern Pacific, would no doubt throw much light on the geographical character of the area to the south. The expedition, moreover, should secure information as to the oceanic circulation and ice-drift which will enable a carefully-thought-out attack on this quadrant to be made. Our knowledge of the Ross quadrant, as Sir Clements Markham has called it, is so limited that it gives us no trustworthy suggestion as to the best lines of entry. And the Joint Committee appears to have accepted the principle that the expedition should work where present knowledge gives most guidance as to profitable lines of discovery and research.

Sketch map of Antarctic area, showing probable connection of the tectonic lines of New Zealand and the Andes through Victoria and Graham Lands. The arrows indicate probable directions of ice movement. The upper half of the map includes the British field of work; the lower half is that assigned to the German expedition.

GEODETIC WORK.

The principal geodetic work of the expedition will be the continuation of the line of gravity determinations that has now been carried from California across the Pacific to Sydney, and thence through Melbourne, Tasmania and New Zealand. This work will be done by a new set of three of the Ellery half-seconds pendulums, which, thanks to Mr. Baracchi, have been made for loan to the expedition by the Victorian Government. The pendulum results will be checked by the use of two of the gravity torsion balances designed by Profs. Threlfall and Pollock.

If it be possible to land for a couple of days at Cape Adare, gravity determinations should be made there as well as at the land station in Southern Victoria Land.

SEISMOLOGY.

At this station a seismographic observatory will also be established. A Milne seismometer of the British Association pattern and a Ewing's duplex recorder are both to be installed.

METEOROLOGY.

A station on shore that will give a complete year's observations is necessary for the meteorological work as well as for the magnetic. The meteorological equipment will be exceptionally complete, thanks to the Admiralty, the Meteorological Council, Dr. R. H. Scott, Dr. H. R. Mill and Mr. W. N. Shaw. Recording instruments, including barographs, thermographs and hygrographs, will be established and checked by four-hourly direct observations; in case of the collapse of the recording instruments, observations will be taken every two hours, and during part of the year it will probably be possible to take them every hour.

As the observatory will probably be near the face of a lofty mountain range, the atmospheric conditions may be abnormal. To ascertain the conditions of the free air, it is proposed to fly kites with meteorographs. The Hargreaves kites, as modified at Dr. Rotch's observatory at Blue Hill, will be used.

The special meteorological problem to be determined by the combined expeditions is the existence of the hypothetical anticyclone over the South Pole. The careful meteorological observations made by Mr. Bernacchi during the Borchgrevink expedition have given almost a complete year's record for Cape Adare; they have shown the prevalence there of south-easterly winds which were unexpectedly warm, and are apparently due to a northern air-current being forced to sea-level and to return northward in the area to the south-east of Cape Adare.

OCEANOGRAPHY.

The expedition is also being generously equipped for oceanographic work, as the Admiralty, thanks to Sir William Wharton, is supplying the whole of the material. The first branch of this work will be the continuation of the contributions of former expeditions to the contour of the Antarctic ocean floor; and it is hoped that, in addition to complete series of soundings in special areas, new lines of soundings will cover a wide area around the edge of the ice-pack. The study of the bottom deposits collected during the soundings will be of especial interest, as bearing on the range and structure of the Antarctic lands; and their evidence will be supplemented by dredging for boulders with a special bucket-dredge.

The determination of the oceanic circulation as shown by the varying temperature, salinity, specific gravity and refractive index of the sea water will be the most arduous part of the oceanographic work. Owing to the importance and difficulty of this research, independent methods will be used concurrently. In the aërial temperature determinations we hope, like the German expedition, to have the assistance of a platinum thermometer, arrangements for which are being made by Prof. Ayrton. The mechanical difficulties in the management of the cable renders it indispensable that a full equipment of mercurial thermometers shall be carried; but electric thermometry has reached a stage at which we may hope that in determining temperatures under the great pressures of oceanic depths we need not rely on a method dependent on volume.

The tidal work will be done at the shore station, where a tide pole will be erected and observations taken for at least three months. Tidal observations on the Antarctic shores, according to Prof. G. H. Darwin, "would be of especially great interest, since this is the only region of the earth in which the water is uninterrupted by land."

Biology.

The biological work of the expedition will be mainly at sea; for the ancient maxim that "Nature loves life" does not appear to apply to the Antarctic lands. The main biological duty of the expedition is to make as extensive a collection of the fauna and flora of the Antarctic Ocean as the ship's storage will admit. As the German expedition proposes to limit its dredging to work of less than a thousand fathoms, it is all the more advisable that the *Discovery* shall dredge in the deep basins as well as in the shallower seas; for though the latter may be richer in individuals, they will probably be comparatively poor in species; whereas the deeper parts of the Antarctic will probably be rich in novelties, and will afford the most valuable materials for the solution of the problem of bipolarity.

Sir John Murray's suggestive views as to the relations of the Arctic and Antarctic faunas are too well known to need re-statement here. His theory is based in the main on the *Challenger* collections, and much further material is required before it can be settled whether the resemblances between the Arctic and Antarctic faunas are homoplastic or homogenetic.

In the zoological work Mr. Hodgson will devote his attention mainly to the invertebrates, and Dr. Wilson to the vertebrates. Mr. Koettlitz will be the botanist of the expedition, and will study especially the phyto-plankton and bacteria of the Antarctic seas.

Geology.

The Antarctic continent being often described as buried completely under a pall of ice and snow is not regarded as a hopeful field for geological work. But though the conditions may be unfavourable, the geological problems of the Antarctic are exceptionally interesting.

Stratigraphically we may expect Wilkes Land to show us a continuation of the rocks of the Australian plateau; and as part of the South Australian coast is at least of Lower Cainozoic age, we may hope for marine deposits of the same age on the northern face of the Antarctic lands. That Palæozoic sediments and limestones occur there is now certain, and they ought to yield fossils if the right zones are exposed. Palæozoic fossils will be of value, but the discovery of Cainozoic land fossils would be of far wider interest. The Biological Committee has called attention to the importance of geological work on the Antarctic lands, and that alone can settle the problems of zoological distribution in South America, South Africa and Australia during Cainozoic times.

It is, however, the way with fossils to occur in soft beds which have been worn into hollows and buried in a country that has been roughly used by the elements. Hence the palæontological results may be meagre, and the palæontological and physical branches of geology will probably gain most from a preliminary traverse.

The glacial work, including the character and distribution of the different ice-agents, the relations of the valley glaciers to the main ice-sheets, the physics of glacier ice, and especially the relation of shearing planes to the orientation of the ice-grains; the distribution of morainic and intraglacial material and the rate of flow of the glaciers are all problems which it is recommended that the members of the expedition should study. Prof. von Drygalski's work in Greenland has called renewed attention to the theory that glacial flow is due to repeated melting and regelation; whereas Müggé's experiments on the shearing planes in ice support the view that plasticity is an essential property of ice. Further experiments on this question will be conducted during the winter on blocks of glacier ice.

The nature of the inland ice is a problem that can only be directly solved by sledge journeys; and if sufficient dog transport be provided, it is hoped that two sledge parties will start from the land station in the early spring. One party will naturally strike westward to cross the mountain range, and the other to the south. How far these parties may be expected to penetrate into the interior will depend on the amount of sledge-hauling power available and on the structure of the country. The westward party would, it is hoped, cross the volcanic mountain chain to the plateau that probably lies beyond it. If the station be established at McMurdo Bay, the southern party ought also to penetrate beyond the coast ranges and discover what lies between the Parry Mountains and the South Pole. On the hypothesis that the South Pacific coast is on the Pacific type of coast structure, then we may expect that the greatest elevations on the Antarctic Lands will lie along the Graham's Land-Victoria Land line, and will be near the sea. To the south of the main mountain range there may be an undulating ice-covered region descending slowly across the Pole to the shore of the Weddell Sea. The main ice-drainages would then be not from the Pole radially in all directions; the ice-shed would run along the Pacific shore with a short steep northern face and a long gradual slope southward to the Pole and across it northward to the Atlantic. That the main ice discharge from the Antarctic lands is into the Weddell Sea is probable, since the biggest of the Antarctic icebergs, including those described as sixty miles long and forty miles broad, are apparently discharged from the Weddell Sea. As these bergs are discharged intermittently, it has been suggested from earthquake action, the Weddell Sea route to the south probably varies greatly in different years, and success in penetrating to the coast-line there might yield comparatively barren results, for the ship would probably be stopped against the stranded border of a vast ice-sheet, and find neither land for a shore station nor harbour for a ship; and travel over the ice-sheet would be unprofitable. As Sir Clements Markham has expressed it, "the Weddell route offers the minimum of results with the maximum of risks."

The Erebus and Terror region, on the other hand, offers a known base of operations, for a landing has already been effected on its shore. And the available geographical, geological and meteorological data all point to it, as in the critical part of the Antarctic lands.

J. W. Gregory.

PRACTICAL PROBLEMS IN THE METALLOGRAPHY OF STEEL.

SINCE Sorby in 1864 established the all-important fact that steel must be regarded as a crystallised igneous rock, his work has been greatly expanded by the international labours of many able microscopists. Much of the work done, however, has been of academical rather than of practical interest, and busy steel works' metallurgists, appalled by the rapid growth of constituents ending in "ite," of "eutectics" and of solid solutions of carbon or carbides in unisolated allotropic modifications of iron, are already beginning to ask themselves the question, Is micrographic analysis going to be of any real use to us, and, if so, in what direction? The present article is an attempt to very briefly answer the above questions.

The theory prevalent a quarter of a century ago that steels of identical chemical composition would necessarily have the same mechanical properties has long since been discarded. But perhaps steel metallurgists have not yet fully realised the disconcerting fact that steel of excellent chemical composition, giving highly satisfactory mechanical tests, may nevertheless utterly fail in use, possibly with disastrous results. In other words, a ductile steel which bends double cold without any sign of flaw or failure may, under the influence of vibration, snap like a piece of glass, though only subjected to mechanical stresses well below its elastic limit.

In connection with the materials of construction used for high-speed engines, both land and marine, it is at the present time a problem of paramount importance for the scientific steel metallurgist to determine the cause of the sudden infidelity of steel (or wrought iron) under vibration.

Data in the writer's possession prove beyond all doubt that steel giving splendid chemical and mechanical tests may rupture under vibration possibly in a few hours or perhaps only after the lapse of twenty years.

There is little doubt that in many cases the microscope is capable of giving warning of the dangerous character of a steel, chemically, and apparently mechanically, safe. To intelligibly describe the structures of safe and dangerous steels it is necessary to consider:

(*a*) The micrographic constituents of structural steel.

(*b*) The molecular migrations of these constituents when at a red heat the metallic mass is in a semi-plastic state.

To put the case concretely, the chemical constituents of a typical rail may (in addition to iron) be approximately taken as carbon 0·40, silicon 0·05, manganese 0·90, sulphur 0·06, phosphorus 0·06 per cent., together with small percentages of arsenic and copper. The micrographic constituents of such a steel are:

(1) The pale, simple constituent ferrite (in this case somewhat impure iron).

(2) The dark etching compound constituent pearlite, consisting of mixed granules of iron and of a double carbide of iron and manganese.

(3) The dove-grey simple constituent sulphide of manganese, MnS.

It is important to remember that in manganiferous steels the foregoing constituents are only completely differentiated visually on slow cooling from a full red heat, a fact which at once introduces the vital question of the migration of constituents. Speaking broadly, it may be said that sulphide of manganese is not, under working conditions, capable of migration to any appreciable extent. Thus it remains to consider only the migrations of the ferrite and pearlite.

The movements of these constituents on heating may be termed "diffusion," and their movements on cooling "segregation."

On heating the typical steel specified to about 700° C. the compound constituent pearlite is converted, with absorption of heat, into the simple constituent, martensite, at Osmond's point A_c1. Then, passing through Osmond's points A_c2–3, the constituents ferrite and martensite diffuse one into the other till, at about 800° C., molecular equilibrium is eventually established.

If, however, the steel be cooled very slowly, the molecules of martensite and of ferrite will perfectly segregate in the respective proportions of about 45 and 55 per cent. Then at Ar. 1, about 640° C., the martensite will decompose into the compound constituent pearlite, which, owing to the presence of manganese, will be granular and not laminated. On the other hand, if the steel is somewhat quickly cooled in air, the segregation of the constituents will be imperfect and the apparent proportion of pearlite relatively large, because, owing to the influence of the manganese present, the phenomenon of constitutional segregation is retarded.

As a matter of fact, the apparently large area of dark pearlite is really an extremely intimate mixture of true pearlite and unsegregated ferrite.

The writer is aware that these statements may provoke theoretical opposition, but they nevertheless describe the

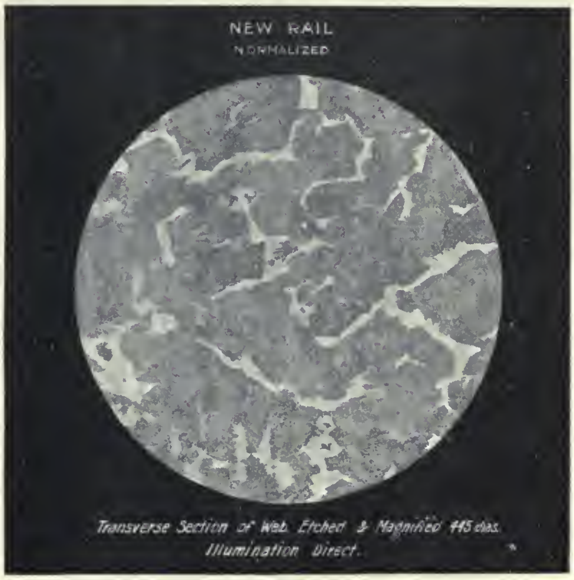

FIG. 1.—Size of original drawing, six inches; magnification, 445 diameters. The magnification here represented is about 166 diameters.

observed facts, and by these, and not by theories, the practical metallurgist must be guided.

The micrograph Fig. 1 shows the transverse section of a rail web re-heated to 900° C. and allowed to cool in air; and this web exhibits the same structure in all the three planes of section presently to be referred to.

The micrograph Fig. 2 shows the structure when the rail was slowly cooled in the re-heating furnace during a period of 50 hours.

In Fig. 1 the pale ferrite has imperfectly segregated in the form of ragged and broken cell walls imperfectly environing cells of pearlite mixed with unsegregated ferrite.

In Fig. 2 the pale ferrite and dark granular pearlite have perfectly segregated mainly in the form of thick, alternating laminæ. The structure last named must be regarded as highly dangerous, because under vibration the adhesion between the constituents is liable to gradually loosen and finally to be destroyed. Nevertheless, mechanical tests would initially reveal little difference in the ductility of the two pieces of rail.

The foregoing facts give the clue to the direction in which the steel microscopist must look for danger with reference to rupture under vibration.

In a brief article it is difficult to do more than give suggestions, but it is necessary to point out that the majority of published micrographs exhibit a single plane of transverse section. Such representation can give only a very partial knowledge of what may be termed the solid geometry of steel.

To determine this it is necessary, in rolled metals, to make three micrographs in three planes of section at right-angles to each other, namely (*a*) a tranverse section, (*b*) a longitudinal horizontal section, (*c*) a longitudinal vertical section. From these the exact form in which any constituent exists in the mass can be determined.

As an example, the case of the constituent sulphide of manganese may be taken. It must be remembered that 0·09 per cent. by weight of sulphur corresponds to no less than 0·5 per cent. by volume of manganese sulphide, a very appreciable amount for a micro-constituent.

In the original ingot during solidification and cooling the sulphide segregates into roughly globular masses

FIG. 2.—Size of original drawing, six inches; magnification, 112 diameters. The magnification here represented is about 42 diameters.

On reheating the ingot for rolling, the sulphide liquefies and the liquid globules are elongated in the direction of the rolling, and necessarily to some extent in a line at right-angles to that direction. Hence in a steel plate, the sulphide may present in the three planes of section above specified the appearances exhibited in Fig. 3, which shows that the sulphide is distributed throughout the steel in the form of irregular, oval laminæ.

It will be obvious that the evil mechanical influence of this constituent will be at its minimum along the length of the plate, somewhat greater across the plate, and at its dangerous maximum through the thickness of the plate.

Perhaps an obstacle to the development of steel works' metallography, even greater than the terror inspired by an unnecessarily complicated nomenclature, is the apparatus, time, care and special reagents supposed to be necessary to obtain, by polishing and etching, a good micro-section. In the advocacy of this view no one has been more earnest than the writer, and for research purposes it is doubtless sound. But for works' purposes, in connection with most steels, it must be confessed that such necessity has been exaggerated.

The writer has, therefore, pleasure in withdrawing his former view owing to experience having proved that by a very much simplified modification of method, a micro-section may be placed upon the stage for examination in five minutes after it leaves the dead smooth file in the machine shop. This process, which entirely does away with elaborate polishing apparatus or special etching reagents, is as follows:

Take two pieces of hard wood, 12″×9″×1″, planed dead smooth on one side; then by means of liquid glue evenly attach to the smooth faces two sheets of the London Emery Works Co.'s Atlas cloth, No. 0. Allow the glue to set under strong pressure. Next, by means of a smooth piece of steel, rub off from one of the blocks as much as possible of the detachable emery. This is No. 2 block, the other, necessarily, No. 1 block.

The steel section, say $\frac{1}{8}$ inch thick and $\frac{1}{2}$ inch diameter, is rubbed for one minute on No. 1 block, the motion being straight and not circular; then, for the same time and in the same manner, rub on No. 2 block. Next place the bright but visibly scratched section in a glass etching dish 3″×1″×$\frac{1}{2}$″, and cover the steel with nitric acid, sp. gr. 1·20.

Watch closely, until in a few seconds the evolved gases adhering to the section change from pale to deep brown and effervescence ensues. Then, under the tap, quickly wash away the acid and for a minute immerse

FIG. 3.

the piece in a second dish containing rectified methylated spirits. Dry the section by pressing it several times on a soft folded linen handkerchief, when it will be ready for examination. The structure will be clearly exhibited, the innumerable fine scratches visible before etching having virtually vanished.

The micrographs illustrating this article were prepared in a very few minutes by the above process, and have been accurately reproduced by Mr. F. Ibbotson. The writer hopes that this simple and rapid method may help to stimulate in steel works' practice a more extensive study of metallography.

J. O. ARNOLD.

THE WORK OF THE REICHSANSTALT.

A THICK quarto volume of nearly five hundred pages[1] gives a full account of the recent scientific researches of the Reichsanstalt. It is impossible, and perhaps not very useful, to attempt in the brief compass of a notice any full description of these varied investigations. All who are interested in physical measurement know that when a paper on any subject is issued from the Reichsanstalt it must be studied by any workers who come after.

In some respects the volume is sad reading to an Englishman. Problems which originated in England have in too many cases received their final solution from the researches of one or more of the distinguished band of workers gathered round the Director, Prof. Kohlrausch.

The volume opens with Dr. Thiessen's research on the

[1] Wissenschaftliche Abhandlungen der Physikalisch Technischen Reichsanstalt. Band iii. Pp. 477. (Berlin: J. Springer, 1900).

thermal expansion of water between 0° and 40°. To this problem Regnault's method of measuring the thermal expansion of mercury is applied, with suitable modifications. Elaborate precautions are taken to secure that the temperature of each of the two balancing columns should be the same throughout, but the difficulty of the measurement lies in determining the difference in level of the ends of these two columns, and Dr. Thiessen's apparatus designed for this purpose proved in his hands most successful. It may perhaps be useful to give the table of the density of water at various temperatures under atmospheric pressure, assuming the density at 4° C. to be unity.

t.	Density according to Thiessen.	Difference from Chappuis' values.
0°	·9998676	− 2
10	·9997270	+ 2
15	·9991263	+22
20	·9982299	+29
25	·9970715	+11
30	·9956736	+19
35	·9940576	+47
40	·9922418	+43

In the third column are given the differences between Chappuis' values found in 1897 and those obtained by Thiessen.

It will be observed that throughout they are very small; indeed a closer examination shows that from 0° to 12° the differences only amount to one or two units in the seventh figure. Chappuis' measurements, it may be mentioned, were made by aid of a dilatometer of platinum-iridium, and involve a knowledge of the thermal expansion of that substance.

In a second paper Dr. Thiessen applies to the same apparatus for measuring the difference of height of two columns to the determination of the pressure of saturated water vapour. The value found for this quantity at 0° C. is 4·579 mm. of mercury, with a probable error of ·001 mm.

Another paper which should have many readers is that by Profs. Jæger and Kahle, on the mercury standards of resistance. This is a continuation of Dr. Jæger's paper in the second volume of the *Transactions* of the Reichsanstalt. A very full description is given of the work of constructing the standards and determining by calibration their resistance in terms of the ohm as defined legally, viz., the resistance of a column of mercury at 0° C., 106·3 centimetres in length and 14·4521 grammes in mass. The tubes were then compared electrically among themselves, and also with the manganin standards of the Reichsanstalt. For this purpose four manganin coils are used. The mean value of the resistance of these four coils at 18° C., as determined from the original tubes calibrated in 1892, was found to be 1·004582, and from the new tubes calibrated in 1897, 1·004578. Changes amounting to about ·00002 were observed in some of the manganin coils during the period of observation.

Dr. Kohlrausch himself contributes a very important paper on the resistance of aqueous solutions of the chlorides and nitrates of the alkalis.

This is followed by a comparison of thermometers made of various kinds of glass, with a further intercomparison of the standard thermometers of the institution.

As regards the depression of the freezing point, the former observations of Wiebe and others are confirmed; it increases for the older kinds of glass, according to a more or less parabolic law, with the temperature to which the thermometer has been raised; while, as before, it is clearly shown that the depression is much greater in glasses containing both soda and potash than it is in glasses which contain either soda or potash only.

Perhaps, however, the most striking results in the volume are those contained in a paper by Drs. Jæger and Diesselhorst on the thermal and electric conductivities, the specific heats and thermo-electromotive forces of certain metals.

When a current passes through a conductor it is heated; when, however, a stationary state is reached, the distribution both of current and of temperature does not change with the time. The conditions for this involve the ratio between the electric and thermal conductivities of the material, and Kohlrausch showed how this ratio might be readily determined by observations on the temperature and potential of three points of a conductor carrying a constant current, provided the ends of the conductor be maintained at a constant temperature.

The theory and the experimental details are both fully given in the paper; the temperatures were determined by the aid of very small thermal elements. The bars of metal experimented on were in most cases about 27 cm. in length, and from 1 to 2 cm. in diameter. The metals examined included gold, silver and platinum, while bars of rhodium and iridium, weighing respectively about ·75 and 1·33 kilogrammes, were prepared by Herr Heræus, but could not be used because of their extreme hardness.

In addition to determining the electric and thermal conductivities at 18° and at 100° C., the specific heats at these two temperatures and their thermo-electromotive forces as against copper were also determined.

Attention had been called by Wiedemann and Franz, in 1853, to the fact that the electrical and thermal conductivities of many substances are approximately proportional, and L. Lorenz, in 1881, had shown that the ratio of the thermal to the electric conductivities at various temperatures is approximately proportional to the absolute temperature. The experiments here described enable us to test these laws. The ratio is shown not to be accurately a constant, it varies in the case of the materials tested, excluding constantan, from 636 for aluminium to 964 for bismuth, but in far the greater number of cases its value lies between 670 and 800, a striking result when it is recollected that the electric conductivities vary between 5 and 60. The temperature coefficient of the ratio ranges, omitting bismuth and one or two high resistance alloys such as constantan and manganin, from ·034 to ·046; if the Lorenz law were true it would be ·0366 in all cases.

Sufficient, perhaps, has been said to indicate the importance of the volume and the high value of the researches which continue to be carried on at the Reichsanstalt.

MEDIÆVAL NATURAL HISTORY IN POLAND.[1]

THERE are few more interesting occupations than to trace the growth of scientific knowledge in the field of natural history. We are heirs of the labours of our forefathers, who were fain to struggle through obscure and devious paths to build up the mass of information on these subjects with which we are furnished. We find them living in a wonderland of the strangest credulity and superstition, and their errors have only gradually disappeared in the process of scientific investigation. With herbs, animals and precious stones were connected the wildest theories. Folk-lore played a busy part; the mandrake uttered groans when it was pulled up; the toad had a jewel in its head; the barnacle was half herb and half animal, and the barometz was a lamb which partook of a vegetable

[1] "Symbola ad historiam naturalem medii ævi. Sredniowieczna Historya Naturalna. Systematyczne zestawienie roslin, zwierzat, mineralow oraz wszystkich innego rodzaju, lekow prostych, uzywanych w Polsce od xii do xvi w. przez Jozefa Rostafinskiego." ("Mediæval Natural History. A systematic account of the plants, animals, minerals and all kinds of simple herbs known in Poland from the twelfth to the sixteenth century." By Joseph Rostafinski. (Cracow: University Press.)

nature. These beliefs have slowly died out, but Sir Thomas Browne, who lived so recently as the latter part of the seventeenth century, in his *Pseudodoxia Epidemica* wrote a book against the delusions of his countrymen, himself believing in many absurdities. The medicinal uses to which animals and herbs were applied strike us forcibly in these modern times. The scientific medical man of the nineteenth century was to be slowly evolved out of the medicine-man and conjurer. Nor are the two last entirely gone; they still may be found in the less civilised parts of Europe and in the more unfrequented nooks of our own country. We have no space to enumerate here the old works treating of popular therapeutics in England, such as the Anglo-Saxon medical books edited by the late Oswald Cockayne, in 1864, under the fantastic title, "Leechcraft and Wort-cunning." The late Mr. Mowat, of Oxford, published two contributions on the subject in his *Alphita* and *Sinonoma Bartholomaei*. Many other works could be cited in English literature, but the immediate object of our article is to call the attention of our readers to the two volumes which have appeared from the pen of Mr. Joseph Rostafinski, professor of botany in the University of Cracow, and the title of which is given at the foot of p. 615. Prof. Rostafinski has furnished lists of the names of plants, animals, minerals and various kinds of herbs which were known in Poland from the twelfth to the sixteenth century. The greater part of these names are preserved in manuscript vocabularies in the libraries of Cracow (especially the so-called Jagiellon), Lemberg, Prague and St. Petersburg. Some of these vocabularies first became known in the pages of the Warsaw review, *Prace Filologiczne*, to which they were contributed by Prof. Brückner, of Berlin, one of the foremost Polish scholars.

For the botanist and student of natural history, these volumes have much value. Prof. Rostafinski catalogues the names of the plants, &c., upon a carefully-arranged system; compares the different names under which they are found, and gives us the Latin equivalents, which will help us in our search for them. He shows us where information has been gathered from Pliny and Dioscorides. His notes abound with folk-lore, and most people know how interesting folk-medicine is. Thus, of the herb koniochrom (*Hippocrepis comosa, L.*) we are told that it has this name (lit., making a horse lame) because if a horse treads upon it his shoe will fall off. The Slavonic appellation for the linden, or lime-tree, is lipa, and comes up in the original Slavonic name for Leipzig, Lipsk. On p. 443, vol. i., we get interesting details of the auerochs, of which a picture is given in Hartknoch's quaint old book on Prussia. It has now been almost exterminated, and is only found in some forests of Lithuania, where it is preserved for the Emperor's hunting. It is singular that in the sixteenth century camels were used in Poland; thus we find them employed in the time of Sigismund Augustus, when that monarch was journeying from Cracow to Wilno. The Slavonic name for camel is derived from the Gothic word ulbandus, which is really a very ancient adaptation of the Greek ἐλέφας.

One of the most curious parts of this interesting book is where the writer deals with the fabulous animals, basilisks, &c. The folk-lore connected with these is abundant. We are reminded of the work of our own countryman, Topsell. In fact, we have a good account of the flora, fauna and minerals, how they were called and what was known of them in Poland during the Middle Ages. Although the scope of the work is in a way limited to Poland, yet, as the author says in his introduction, which appears in Latin as well as in Polish, the book will be serviceable for north Europe generally. There is in reality a great unanimity in many of these legends about plants and animals. Pliny leads off, we may say, in his "Natural History," which was the great storehouse during the Middle Ages for folk-lore of all kinds. We must not forget, also, Bartholomæus' "De Proprietatibus Rerum," *a.* 1400. The Slavonic riches are being gradually collected; much has been already done in Russian, and the late Mr. Ralston made use of it in his books of Russian folk-songs and Russian folk-tales. The *Sbornik*, or *Miscellany*, published yearly by the Bulgarian Government, generally devotes a section of each new volume to these popular traditions. In England we have no special organ, except it be the *Folk-lore Journal*; our popular superstitions must be gathered from the miscellaneous pages of *Notes and Queries* and such books as "Gerard's Herbal." No little light is afforded by the curious medical works published in the sixteenth and seventeenth centuries, among which may be expressly mentioned the "Breuyary" of Andrew Borde and the choicely quaint work of Dr. Tobias Venner. In the life of Seth Ward, by Dr. Walter Pope, some extraordinary tales are told of a surgical operator of that time, and also in Aubrey's Lives.

In all countries the popular names given to plants may be said to be richly significant, and therefore not only the man of science, but the philologist may find much material in Prof. Rostafinski's volumes.

INTERNATIONAL ASSOCIATION OF ACADEMIES.

The meetings of the International Association of Acadamies were concluded last Saturday, when it was determined unanimously that the next Congress should be held in London in 1904. Although the *Comptes rendus* of the various meetings have not yet been published, it is known that much useful work has been accomplished. Nothing could exceed the cordiality of the reception accorded to the foreign delegates by the French authorities and their scientific *confrères*. After the final meeting on Saturday, the delegates were received by the President of the Republic and Madame Loubet, and later in the day they attended a dinner and concert given in their honour at the Hôtel de Ville.

NOTES.

As already announced, a complimentary dinner to Sir Archibald Geikie will be given next Wednesday, May 1, at the Criterion Restaurant. A number of distinguished men of science will be present, and the chair will be occupied by Lord Avebury. It is felt that the retirement of Sir Archibald Geikie from the position of director-general of the Geological Survey should not be permitted to pass without an expression of appreciation of his services to science and to the nation. All who are able will, we are sure, show by their presence at the dinner that they delight to do honour to one who has worked so worthily and with such success for the extension of scientific knowledge. Tickets may be obtained from Mr. F. W. Rudler, 28, Jermyn Street, S.W.

We regret to see the announcement of the death of Prof. H. A. Rowland, professor of physics at the Johns Hopkins University, Baltimore, U.S.A.

The Australian mail brings us news that Messrs. Baldwin Spencer and Gillen left Adelaide on March 15 for their twelve months' North Australian expedition. Owing to the presence of drought in the interior, the start, which was to have been made early in February, had to be delayed. The original intention of the explorers was to have worked out through the McDonnell Range and the Arunta tribes, and then north, until the mouth of either the Daly or Victoria river was reached; but it seems likely that this course might have to be given up in preference for an inverse one starting from Port Darwin,

which, with either the north and east or the west coast, was to have been the returning route. Our information from the explorers themselves is that they have simply "started away for the far north," but it affords us great pleasure to add that it embodies the news that, in addition to the 1000*l*. contributed to the expenses of the expedition by Mr. D. Syme, of the Melbourne *Argus*, there has been given a further sum of 500*l*. by Mr. Reuben Spencer, of Darley Hall, Manchester, father of the leader.

THE committee of the National Physical Laboratory will shortly appoint several members of the staff of the laboratory. Applications are invited for the post of superintendent of the engineering department; and other appointments to be made include two or three assistants in the physics department—one of them to take charge of chemical investigations—and a few unior assistants. Particulars as to salaries, &c., will be found in our advertisement columns.

MANY people wonder why the Thames is not used for passenger traffic to the same extent as the Seine. With a quick and punctual service, and neat vessels, the Thames might become the most popular means of travel in the metropolis. The Thames Steamboat Company possesses thirty-six vessels, having a total carrying capacity of more than sixteen thousand passengers. The vessels will be reviewed on May 1, and the service will commence on the following day. There will be a ten-minutes service between London Bridge and Battersea, a half-an-hour service between Chelsea and Kew, and a service of the same frequency eastwards from Westminster to Greenwich and Woolwich. It is sometimes objected that on account of the windings of the river the distance from one point to another is much greater than by road; but it must be remembered that omnibuses—with which the steamboats are comparable—follow routes which deviate from a direct line almost as much as the river. The better the service of steamboats on the Thames the more people will take advantage of this pleasant means of communication, and in the course of time London might be so well served in this respect as Paris is now.

THE Senate of Minnesota has passed a Bill prohibiting the marriage of insane, epileptic and idiotic persons, and requiring a medical certificate of all applicants for marriage licenses.

WE learn from *Engineering* that the valuable collection of early scientific works made by the late Mr. Latimer Clark, F.R.S., has been purchased by Mr. S. S. Wheeler and presented to the American Institute of Electrical Engineers. Mr. Andrew Carnegie has offered to provide the large sum necessary to house the entire collection in its new quarters.

THE Agricultural Research Association is a Scottish organisation, founded about twenty-five years ago and having for its objects the carrying out of two branches of work of the utmost importance to farmers, viz. scientific investigations bearing upon agriculture, and the dissemination of the information thus obtained among those to whom it is likely to be of practical use. The research station is at Glasterberry, Milltimber, Aberdeen. The Association has a strong list of names of patrons, office-bearers and members of the executive committee, and the director of research is Mr. Thomas Jamieson, of Aberdeen, under whose able administration some excellent work has been carried out and many most valuable results have been made public. From the report of the Association for the year 1900 it appears that experiments have at various times been conducted on the comparative values of finely ground and soluble phosphates, on the aperture in root hairs, on the relative values of different forms of nitrogenous, phosphatic and potash manures, on the cause of finger and toe disease in turnips, on the characters of roots of grasses and clovers, on the permanence of rye grass, and other subjects. Among the more recent inquiries has been a most carefully conducted set of experiments demonstrating that natural cross-fertilisation of oats leads to larger and more productive crops without extra outlay. It is proposed to extend the experiments to other crops in view of the decisive results obtained with oats. The Association is dependent on the subscriptions of landowners and farmers, and although the latter take the greatest personal interest in the work, the amount of the subscriptions has been insufficient to meet the necessary expenditure, and the director has in consequence had to meet the deficiency incurred during last year's work. In view of the practical value, to say nothing of the scientific importance, of the results hitherto achieved, it is to be hoped that the appeal of the committee for a further measure of support will meet with that response on the part of the landowners which the work of the Association most certainly merits.

THE Easter party is now at work at the Port Erin Biological Station. The curator, Mr. H. C. Chadwick, who has recently been for a couple of weeks at the Lancashire Sea-Fisheries Hatchery, making himself acquainted with the methods employed there, has now returned to Port Erin, and Prof. Herdman is there with a party of students. Dr. O. V. Darbishire, from Owens College, occupies a table and is at work on his forthcoming L.M.B.C. memoir on Gigartina; Miss Thornely, of Liverpool, is examining Polyzoa, and there are three senior students from the zoological department of Owens College at work. Other naturalists are expected during the latter part of this month. The boisterous weather of late has prevented much work at sea, but several shore collecting expeditions have taken place, and arrangements have been made for a steam-trawler for dredging. This is a late season amongst marine animals in the Irish Sea, probably on account of the recent cold weather. The fish spawning is not so far advanced as is usual at this time, and sedentary colonial animals, like compound ascidians, on the shore seem to be less abundant and smaller than usual. In the tanks of the Aquarium several common shore invertebrates are now spawning; Ephyræ made their appearance in swarms during the greater part of March; *Porania pulvillus*, obtained on dredging expeditions from deep water, has established itself and is living healthily; while several of the large wooden tanks contain crops of self-planted algæ and other small organisms, and support a varied fauna without change of water and with very little attention.

WE learn from *Science* that the following grants from the Gould Fund have recently been made:—to Mr. John A. Parkhurst, 30 dollars; to Dr. Herman S. Davis, 500 dollars; to Mr. Paul S. Yendell, 225 dollars; to Prof. Simon Newcomb, 25 dollars. A considerable additional amount of income has accrued, for the distribution of which applications are awaited. These applications may be made by letter to any of the directors, stating the amount desired, the nature of the proposed investigation, and the manner in which the money is to be expended. The directors, desiring to stimulate the participation of American astronomers in the attempt to bring up the arrears of cometary research, offer to them the sum of 500 dollars for computation of the "definitive" orbits of comets, this sum to be distributed at the average rate of 100 dollars for each computation—the amount to vary according to the relative difficulty of the computation, and to be determined by the directors of the Gould Fund. Computers should promptly notify the directors of their participation or desire to participate, and manuscripts should be submitted not later than July 1, 1902.

Apropos of the red rains of African dust which have recently excited considerable attention in the south of Italy, Dr. H. R. Mill, the editor of *Symons's Meteorological Magazine*, directs attention, in the issue for the current month, to a blood-rain plant which has invaded the large evaporation tank at Camden

Square. The plant has been examined microscopically by Mr. V. H. Blackman, of the Botanical Department of the British Museum, and is found to be a minute motile alga called *Sphaerella pluvialis*. It is usually found in small pools, and is closely allied to the microscopic plant which gives its colour to red snow. Its occurrence in rain is a rarity, and it has nothing in common with the red sand-rains of the Continent—except the colour—but if a whirlwind were to pass over the tank, showers coloured red might be produced along its subsequent track by the same process as the familiar showers of frogs and fish.

We have received from the director of the Meteorological Service of Canada an interesting account of the cloud observations made at the Toronto Observatory during 1896 and 1897. The instruments used consisted essentially of two ordinary surveyor's theodolites, the telescopes being replaced by a long axis made for each and mounted in the Y's of the standards. The length of the base line was 1552 metres; the observer at one station selects some well-defined point of a cloud and telephones its position to the observer at the other station, and on his identifying it the two observers sight it at the same instant of time, and this operation is repeated after an interval varying from 40 seconds to 8 or 10 minutes. Not much photography was done, owing to the difficulty of keeping the cameras in adjustment. The highest cirrus measured in the latter part of 1896 was at 10,000 metres, velocity 79 miles an hour, and the lowest 8100 metres, velocity 55 miles. In June 1897, altitudes exceeding 11,000 metres were obtained, with velocities of about 100 to 150 miles an hour. Mean height during the summer season was 10,900 metres, mean velocity 40 miles, and in the winter season 9,978 metres, velocity 26 miles. The heights and velocities of the various clouds are given in the same way, the mean heights of the lowest cloud, the cumulus, being in the summer season 1697 metres and in the winter season 1326 metres; the mean velocity was only about 10 miles an hour.

The second sheet of the North Atlantic and Mediterranean Pilot Charts, issued by the Meteorological Office last week, exhibits the salient features of the region in the month of May. In dealing with the winds it is pointed out that, as indicated by the isobars on one of the inset charts, the barometric gradient between the anticyclone of the horse latitudes and the depression near Iceland is now only about ¼ inch, so that the winds over the northern half of the Atlantic are of moderate force and strong gales are uncommon, the southern limit of 10 per cent. frequency of gales receding northward to between the 45th and and 50th parallels. Some characteristics of the tornadoes on the African coast are mentioned, and advice given as to how a vessel should be handled. It is instructive to observe that with the advance of the year fog is not only increasing on the banks but the area is creeping eastward, while another area is spreading westward from the Bay of Biscay. The great advantages of ocean current charts for each month of the year are becoming very evident. To quote the latest chart, "The results show the changes, both local and general, which are associated with the advance of the seasons. In the month of May it will be seen that to the westward of the British Isles, between the 50th and 60th parallels, the drift is largely to the west and south-west, there being no evidence of the north-eastward extension of the Gulf Stream beyond about 47° N., 27° W. Between the 30th and 50th parallels westward to the 30th meridian, nearly the whole of the surface water has a south-going movement. These features are probably closely related to the prevalence of polar winds off the coasts of North-Western Europe at this season." The distribution of atmospheric pressure, with the accompanying northerly winds, distinguishing the European "Cold Spell" of May, is illustrated by means of an inset chart and remarks, and there is information bearing on several other topics; but sufficient has been said to show that the chart may be of service to many others in addition to seamen.

The Sydney Botanic Gardens, which are admittedly among the finest in existence, comprise about forty acres, and their northern edge forms a semicircle round Farm Cove, one of the many charming indents of the harbour, and forming the anchorage of the vessels belonging to the Australasian squadron. Adjoining the western boundary of the gardens are the grounds surrounding the residence of the Australian Governor-General. Recently the gardens have been enriched by the addition of the first museum in Australia strictly botanical in character, all existing museums in which plant products are exhibited being either technological or partly botanical and partly technological. The building, which has been erected under the supervision of the State Government architect, now comprises a museum, herbarium, library, store room, photographic room, seed room and offices. The museum was formally opened by Mrs. John See, whose husband, the acting-Premier and Chief Secretary of New South Wales, said the collection was a national one, and that so long as he occupied the position he would do all he could to provide money for extending its usefulness.

Dr. B. Sharp described, at a recent meeting of the Academy of Natural Sciences of Philadelphia, some observations he has made on the contents of the stomachs of the common cod. Several hundred stomachs were opened with the hope of finding shells of gastropods and bivalves. Numerous valuable shells were taken from the cod years ago by Stimpson and Gould on the New England coast, north of Cape Cod, and it was supposed that similar finds would come to light from the cod caught off Nantucket. The stomachs examined were filled almost exclusively with crustaceans and for the most part with species of Panopeus. Hermit crabs, without shells, and a few Crepidulæ were also seen. Here and there young lobsters were found in the stomachs, occasionally two in one stomach. Dr. Sharp believes that the decrease in quantity of the lobsters, which has been so marked within the past few years, is partly due to their consumption by the cod; and as these have of late greatly increased in numbers, owing to the work of the United States Fish Commission, the lobsters have not been able to keep pace with the increase of their enemies.

Petermann's Mitteilungen contains a short descriptive paper on the region surrounding the junction of the Trombetas with the Amazon, by Dr. Friedrich Katzer, with a map based on surveys made under direction of the Belgian engineer, Haag, chiefly by Captains Le Blanc and Robert. The map indicates considerable modifications of those already extant.

Prof. E. Richter communicates to *Petermann's Mitteilungen* a letter addressed to him by Herr Schuh, of Gmunden, on some temperature observations made in the Gmunden See, which seem to settle the question of why water at the surface of a lake on which ice is forming has always been recorded as warmer than the freezing point. Using an ordinary thermometer, Herr Schuh observed temperatures of 0°·4, 1°·5, 2°·0 and 3°·4 C. within an area of 1 sq. m. on which ice was actually forming. A special form of thermometer was then devised, of which the lower part was drawn out into the form of a pear 7 mm. in diameter, the instrument being filled with spirit and carrying a minimum index, and the whole was so arranged as to swim on the water with the pear-shaped part immersed horizontally. Repeated observations showed that where ice was forming the spirit showed a temperature of 1° to 3° when the instrument was lifted out of the water, but the index invariably read 0° C. Hence it appears that the

ice-forming layer is one of extreme thinness just at the surface, and that in observing with the ordinary thermometer this layer gets mixed with the warmer water underneath.

A MATHEMATICAL investigation of the motions of seismographs, which from its nature bids fair to have important applications, is published by Dr. M. Contarini in the *Atti dei Lincei*, x. 5, 6. In it the author determines the differential equations regulating the motion of the forms of seismograph considered relative to three rectangular axes, and shows how these equations may be integrated. The assumption on which this work is based is that all the points of attachment, both of the pendular masses and of the registering levers, are treated as being rigidly connected with the earth.

IN the *Bulletin* of the Cracow Academy, November 1900, Herr Zorawski studies the motion of a continuous system of material points regarded as a group with the infinitesimal transformation determined by the well-known operator of the ordinary equations of hydrodynamics. It appears that if the characteristic equation possesses three distinct roots, the principal axes of the quadric connecting the rates of strain are transformed into principal axes, if two roots of the characteristic equation are equal only one principal axis is transformed into a principal axis, finally, in the case of a triple root, the line element possesses properties which the author designates as "perfectly symmetrical."

THE resistance of cereal smuts to formalin and hot water forms the subject of a short paper by Mr. William Stuart in the *Proceedings* for 1898 of the Indiana Academy of Science, which has recently reached us. The results obtained in the treatment of the spores are well within the bounds of successful practice, the spores being much more easily injured with either hot water or formalin than is the grain. It is apparent that the essential feature in the successful treatment of grain for smut is to bring each seed in contact with the solution used for a sufficent length of time to enable it to reach the spores. The advantage possessed by formalin over hot water in the treatment of seed grain lies in its greater ease of application, doing away with the necessity of heating water and maintaining a sufficiently uniform temperature during the treatment. Mr. Mason B. Thomas describes some field experiments with formalin in the same volume.

PART 67 of the *Communications* from the Leyden Physical Laboratory contains a paper by J. C. Schalkwijk on precise isothermals, in which the author describes methods of determining the corrections to be applied in taking account of the volume of the meniscus of mercury in working with standard gas-manometers.

A DISCUSSION on the properties of steel containing nickel is presented to the Report of the Congrés International des Méthodes d'Essai (Paris, 1900). In passing from ordinary steel to that containing a considerable proportion of nickel the principal changes are the lowering of the temperature of transformation of the carbon, the fusion of two of the transformations and the exaggeration of the phenomena accompanying the double point. In ferro-nickels containing traces of carbon, but more than 20 per cent. of nickel, the transformations are determined by the nickel, the carbon acting as a retardent. It appears that the magnetic properties are due to a certain molecular transformation which takes place with evolution of heat, and when this molecular grouping is prevented by the presence of some other body, the metal may be reduced to ordinary temperatures without exhibiting magnetic phenomena. The author compares ferro-nickels to solutions rather than combinations. Finally, it is suggested that by the addition of nickel many properties of steel may be studied at temperatures considerably below those at which they occur in pure steel. As an example the author mentions the gradual changes of volume which take place in the course of years, and which in the case of nickel steels may be observed at the temperature of the laboratory, whereas it would be impossible to study similar changes occurring at an elevated temperature in pure steel.

IN the April number of the *Zoologist* Mr. J. H. Gurney mentions that the nestling of the green woodpecker, when a few days old, develops a pea-like knob on each side of the hinder part of the mandible. It would be interesting to discover the use of this peculiar growth, which appears to have been hitherto unnoticed.

A LARGE portion of vol. xxii. part 3 of *Notes* from the Leyden Museum is taken up by instalments of Dr. O. Finsch's catalogue of the birds in the collection; these deal with certain eagles, the parrots of the South Sea islands, and various passerines. Another article, by Dr. Jentink, treats of certain alleged errors in the description of the large West African diuker antelope (*Cephalophus sylvicultor*). Considering that one of the articles is dated March 1901, it is somewhat difficult to understand why this part of the *Notes* is issued for July 1900.

PART 3 of vol. lxix. of the *Zeitschrift für wissenschaftliche Zoologie* contains six memoirs, five of which deal with the anatomy and morphology of invertebrates, while the sixth (by Herr E. Botezat) treats of the nerves of the hard palate of mammals, a subject which has hitherto received but little attention from anatomists. To specialists, Prof. F. Vejdovský's communication on the morphology of the antennæ and shell-glands of the crustacea should prove interesting. Another paper, by Herr N. Kassianow, deals with the nervous system of the lucernarian medusæ.

THE concluding portion of Mr. E. J. B. Sopp's address on the importance of the study of life-history among insects is published in the *Entomologist* for April. After mentioning that insects in captivity are often somewhat misleading in their habits, and that all observations should be verified on specimens in the wild condition, the author cites a few instances where our ignorance of insect physiology is most noticeable. It is quite unknown, for example, how the water-beetles of the genus Dytiscus produce their well-known stridulating sound. Neither do we know the use of the peculiar cord-like structure found in "bloodworms," or larvæ of the gnat-like fly *Chironomus plumosus*, nor how the respiratory air-sacs of the "phantom larvæ" of another gnat, *Corethra plumicornis*, become inflated with air, and that, too, in all probability of a highly oxygenated character. The author also calls attention to the importance of coalition between natural history societies for the purpose of recording the local abundance of insects in their respective districts. It is the common and not the rare species to which attention should be directed, as by this means we may in time be able to predict and thus prevent the appearance of "plagues" of noxious kinds.

A DESCRIPTIVE catalogue of the Coleoptera of South Africa, by Mr. L. Péringuey, assistant director of the South African Museum, constitutes vol. xii. of the *Transactions* of the South African Philosophical Society. The catalogue occupies 563 pages, and is illustrated by nine plates.

WE have received a copy of *Electrical Investments*, a new fortnightly journal devoted mainly to the financial side of electrical undertakings. Besides an extensive share list, the paper contains a leading article and comments on matters of interest to those concerned, financially or otherwise, with electrical matters.

IT will interest archæologists to know that the concluding volume (vol. iv.) of "Old Northern Runic Monuments of Scandinavia and England," by the late Prof. George Stephens, will be published shortly in English by Messrs. Williams and Norgate. The work was left incomplete by Prof. Stephens, but from his notes and papers his son has been enabled to prepare the volume for publication.

MUCH information not easily obtainable is brought together in a little publication just added to the Patent Office Library Series, of which it forms No. 4, under the title "Guide to the Search Department of the Patent Office Library, with a Dictionary of 'Trade or Fancy' Names." The book shows in what publications, and for what periods, grants of patents and registration of trade marks and designs are recorded, the information being arranged under the names of countries. The dictionary of words used to designate materials, processes and mechanical appliances will often prove of service, for the etymology of the words rarely gives a clue to the nature of the things designated.

THE *Proceedings* of the American Association for the Advancement of Science, containing addresses and abstracts of papers read at the forty-ninth meeting, held last June in New York, have just been received. By an arrangement with the Macmillan Company, members of the Association now receive the weekly journal, *Science*, free of charge; and as the journal publishes the official notices and proceedings of the Association, the members are kept in touch with these affairs as well as with the progress of science in return for their single subscription.

THE *Psychological Index* this year occupies 179 pages of the special number of the *Psychological Review*. The index is a bibliography of the literature of psychology and cognate subjects for the year 1900, and includes publications in all languages, together with translations and new editions in French, German and English. There is a comprehensive subject-index, containing 2627 entries, and also an authors' index. Prof. H. C. Warren, of Princeton University, who is the compiler of the index, deserves the thanks of psychologists for the careful way in which he has done his work.

"THE Handbook of Jamaica" for 1901, compiled by Messrs. T. L. Roxburgh and J. C. Ford, has been published by Mr. Edward Stanford. The work is now in its twenty-first year of publication, and contains an immense amount of historical, statistical and general information concerning the island

THE additions to the Zoological Society's Gardens during the past week include a Macaque Monkey (*Macacus cynomolgus*) from India, presented by the Rev. J. M. Glubb; a Bennett's Wallaby (*Macropus bennetti*) from Tasmania, presented by Mrs. L. Brown; a Water Rail (*Rallus aquaticus*), British, presented by Mr. A. W. Arrowsmith; a Blue-breasted Waxbill (*Estrelda cyanogastra*) from West Africa, presented by Miss E. C. Stephens; a Raven (*Corvus corax*), European, presented by Mr. J. C. Cadogan; two Red-eared Bulbuls (*Pycnonotus jocosus*), a Red-vented Bulbul (*Pycnonotus haemorrhous*) from India, a Chinese Bulbul (*Pycnonotus sinensis*), a Chinese White-eye (*Zosterops simplex*), a Chinese Mynah (*Acridotheres cristatellus*) from China, a Wattled Honey-eater (*Anthochaera carunculata*) from Australia, a Black Tanager (*Tachyphonus melaleucus*), a Silky Cow-bird (*Molothrus bonariensis*), a Red-headed Marsh-bird (*Agelaeus ruficapillus*), two Sulphury Tyrants (*Pitangus sulphuratus*) from South America, a Brazilian Tanager (*Ramphocoelus brasilius*), a Red-headed Cardinal (*Paroaria larvata*), a Brazilian Hangnest (*Icterus jamaicai*), a Bay Cow-bird (*Molothrus badius*) from Brazil, a Black-tailed Hawfinch (*Coccothraustes melanurus*) from Japan, a Long-tailed Glossy Starling (*Lamprotornis aeneus*) from West Africa, a Nutcracker (*Nucifraga caryocatactes*), European, two Black Larks (*Melanocorypha yeltonensis*) from Siberia, presented by Mr. J. M. C. Johnston; a One-wattled Cassowary (*Casuarius uniappendiculatus*) from New Guinea, a Blackish Sternothere (*Sternothoerus nigricans*) from Madagascar, Six Ceylonese Terrapins (*Nicoria trijuga*), three Bungoma River Turtle (*Emyda granosa*) from India, a Black Tortoise (*Testudo nigra*) from the Galapagos Islands, deposited; a Garnett's Galago (*Galago garnetti*) from East Africa, three Brazilian Grosbeaks (*Guiraca cyanea*) from Brazil, purchased.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN MAY.

May 1.	15h. 18m. to 16h. 19m. Moon occults *i* Virginis (mag. 5·5).
1–6.	Epoch of Aquarid meteoric shower (Radiant 338°—2°).
3.	4h. 6m. to 8h. 55m. A penumbral eclipse of the moon.
3.	6h. 31m. Middle of the eclipse.
3.	7h. 28m. Moon rises at Greenwich.
7.	12h. 39m. to 13h. 51m. Moon occults 21 Sagittarii (mag. 4·9).
8.	12h. 26m. to 13h. 23m. Moon occults *d* Sagittarii (mag. 4·9).
8.	13h. Saturn in conjunction with moon. Saturn 3° 48′ South.
9.	13h. 3m. to 14h. 59m. Transit of Jupiter's Sat. IV.
12.	11h. 48m. Minimum of Algol (β Persei).
13.	13h. 57m. to 14h. 48m. Moon occults λ Piscium (mag. 4·7).
14.	11h. 30m. to 14h. 34m. Transit of Jupiter's Sat. III.
15.	Venus. Illuminated portion of disc = 0·998.
15.	Mars. Illuminated portion of disc = 0·895.
17.	17h. 29m. Sun eclipsed, invisible at Greenwich.
21.	15h. 1m. Transit (ingress) of Jupiter's Sat. III.
25.	Saturn. Outer minor axis of outer ring = 17″·06.
31.	11h. 49m. to 12h. 36m. Moon occults B.A.C. 5109 (mag. 5·4).

NEW VARIABLE STAR 70 (1901) URSA MAJORIS.—In the *Astronomische Nachrichten* (Bd. 155, No. 3701) Dr. T. D. Anderson announces the discovery of a new variable star having the position

$$\left.\begin{array}{l}\text{R.A.} = 8\text{h. } 57\cdot9\text{m.}\\ \text{Decl.} = +51° \;\; 42'\end{array}\right\}(1855).$$

The magnitudes observed were :—

1901	February	13	...	10·4
		15	...	10·4
	March	24	...	9·8
		27	...	9·7
	April	3	...	9·6

NOVA PERSEI.—Prof. H. C. Vogel gives particulars of some of his later work on the spectrum of the new star in the *Astronomische Nachrichten* (Bd. 155, No. 3701). Measures of seven lines between H_α and H_β are given, being ascribed to sodium, helium and possibly magnesium. A discussion is included of the possible explanation of the great width of the lines by the work of Humphrey and Mohler, Wilsing and others.

Herr J. Plassmann, the well-known variable star observer, gives a series of estimates, by Argelander's method, of the brightness of the Nova from February 23 to March 27. In many cases estimates taken at different times during the same night show the variation of the star (*Astronomische Nachrichten*, No. 3705).

REDUCTION OF PHOTOGRAPHS OF STELLAR SPECTRA.—Nos. 3702–3 of the *Astronomische Nachrichten* are devoted to a treatise by Dr. Hartmann on the measurement and reduction of photographs of stellar spectra, using the dispersion formula put forward by him some time ago, with special reference to the determination of velocities in the line of sight.

DR. METCHNIKOFF ON MICROBES AND THE HUMAN BODY.

A SPECIAL meeting of the Manchester Literary and Philosophical Society was held on Monday, April 22, when Dr. Elie Metchnikoff, of the Pasteur Institute, Paris, delivered the Wilde Lecture. Before the lecture, the president of the Society (Prof. Lamb) presented the Wilde Medal for 1901 to Dr. Metchnikoff, and the Wilde Premium for 1901 to Mr. Thomas Thorp.

Dr. Metchnikoff's lecture, which was in French, was on "La Flore microbienne du Corps humain." Dr. Metchnikoff explained that men were free from microbes at birth, but immediately after birth the surface of the skin and the mucous membranes became peopled with them, and at the end of some days they were numerous and varied. Their germs were derived from the air, or from the water used in washing the child. In summer they developed faster than in winter, and sometimes within four hours after birth there would be found several different sorts of microbes in the intestines. But as a rule their appearance was first observed between the tenth and seventeenth hour after birth. The habitation preferred by the microbes found in the skin was unquestionably the capillary follicles, a kind of deep sheath for the formation of hair. The mucous membranes, the surface of which was always moist and covered with substances by which microbes were readily nourished, were generally supplied with them more abundantly than the skin. The conjunctiva of the eye, however, thanks to its being continually washed by tears, usually rid itself of most of the microbes that found their way into the eye either with the fine dust in the air or through contact with the fingers. There was no doubt that microbes penetrated into the very deepest parts of the respiratory passages, though it was difficult to give a precise account of those ordinarily inhabiting the windpipe, the bronchial tubes and the lungs, since the presence of those which are found there after death might be explained by the intrusion, after death, of microbes from adjacent organs of the body. However that might be, the growth of microbes in the lower respiratory passages ought never, in a healthy man, to be great.

It was the digestive organs that exhibited them in the greatest abundance. Dr. Miller, of Berlin, had described more than thirty species inhabiting the cavity of the human mouth, some of them also to be found on the human skin; others, which were found about the teeth, were peculiar to the mouth and were not met with anywhere else. Several of the species characteristic of the mouth made their way deep into the digestive organs and were recognisable in the stomach and the intestines. The stomach, with its acid contents, offered conditions affecting in a quite exceptional way the development of microscopic growths. Many kinds of bacteria could not endure an acid environment; still, the bacterial system of the human stomach was pretty rich, thirty different species having already been distinguished, most of which were not found elsewhere in the digestive system. In the stomach, and still more in the small intestine, bacilli were the predominating form of microbe, the number and relative proportions of microbes in the small intestine varying with the food eaten. Meat and vegetable diets respectively stimulated the development of special bacterial forms, though even when the diet was unaltered noteworthy fluctuations in the microbian population were observable. From the smaller intestine the microbes passed to the larger, where they were joined by a great number of new kinds. Of all the parts of the human body, the large intestine was undoubtedly the most abundantly teeming with these growths. It was inhabited by about forty-five species of microbe, chiefly bacteria, among which bacilli were much the most numerous. The large intestine began to be inhabited immediately after birth. Even on the first day of life, before any food whatever had been taken, a fairly great variety of microbes was to be found there. When the child was suckled the population of the large intestine very soon underwent a change. It became more uniform and was composed mainly, and sometimes almost exclusively, of a particular bacillus. In children fed with the bottle, on cow's milk, this bacillus was found too, but in smaller numbers, the large intestine in these children being much richer in microbes of various types. After weaning, the abundance of microbes became much greater still. The number of distinct species of microbes to be found in a man in health could not be exactly estimated, but quite roughly and provisionally might be put between sixty and seventy.

What could one say of the function of these varied growths? Among invertebrate animals there were some covered with much more copious growths than were found on the human skin. On the southern and western coasts of England there was found in great numbers a kind of crab whose whole shell was generally covered thickly with vegetable growths. Their use was obvious. They assimilated the crab to the marine vegetation, and made him invisible alike to his enemies and to his prey. No such demonstration could be given of the utility of the microbes on the human skin. On the other hand, the flora of the cavity of the mouth might render man a service. Everybody had noticed that wounds inside the mouth healed much sooner than those on the outer skin. Moistened by the saliva, the wounds remained in contact with the microbes and their soluble products, which stimulated in a marked degree the reaction of the human organism. The secretions of the microbes attracted a great number of white blood-corpuscles, which cleaned the wound, cleared it of microbes and mortified tissues, and so favoured the process of recovery. In the lower parts of the digestive system this function of microbes was less important, the mucous membrane there being much more seldom torn. But it was probable that the acids secreted by many bacteria in the small intestine rendered a real service by preventing the development of certain other microbes which might impede digestion. This preventive function was manifested also in the course of conflict between the human organism and microbes of a very dangerous kind, and there was reason to believe that in some cases the germs of Asiatic cholera were rendered innocuous by the action of the microbes which they encountered in the intestines. It had also been contended by some authorities that the microbes in the digestive system played an important part in the digesting of food, and that without them food could not be assimilated; but the data available would lead rather to the general conclusion that for the normal action of the human digestion the presence of the intestinal microbes was by no means indispensable.

They should now try to ascertain whether the microbes in the human system might injure its health. When the defensive forces of the body flagged, whatever might be the reason, the microbes on the skin began to multiply and to pour their noxious products into the tissues and the blood. It often happened that serious boils and anthrax developed themselves in persons suffering from diabetes or some other general disease, their cause being, not the introduction of a morbid germ from without, but the excessive multiplication of certain microbes which are found in the healthy human skin and which now took advantage of the enfeeblement of the defensive cells. But the greatest harm was done by the microbes of the stomach and intestines. It had been recognised that the gravity of the danger incurred in cases of perforation of the intestines was due to the inflammatory action of the microbes that escaped into the peritoneum. Nor was the injurious effect restricted to cases where the microbes penetrated directly into the other organs or into the blood, for the microbes produced soluble substances which could be absorbed through the wall of the intestines and so make their way into the circulation. Several of these were substances more or less poisonous in their action, and it was very probable that a great many of these toxic products of our intestinal flora had still to be ascertained. In spite of our imperfect knowledge, there was reason to state, with the greatest strength of conviction, that the poisons produced by the intestinal microbes played a considerable part in causing many and various maladies. Headaches, exhaustion, neurasthenia, dyspeptic asthma, certain forms of epilepsy, several skin diseases, including acne, had by certain authorities been attributed wholly or in part to the action of poisons originated in the digestive system. Even in cases of mental disease its importance could not be denied; it had a noteworthy connection with diseases involving atrophy of the higher organs, such as the brain, the heart, the kidneys and the liver.

Dr. Metchnikoff then discussed at some length the relations of the normal microbian population of the human body—that is, the microbes present in it in a state of health—and the pathological microbes, or microbes directly inducing specific disease. He pointed to the methods practised in medicine and surgery to limit or counteract the action of microbes ascertainedly or potentially generative of disease, and to what he believed to be limitations to the beneficial operation of antiseptics. There was a tendency to renounce more or less completely the use of antiseptics, and to have recourse more and more to simply mechanical measures for keeping microbes out of the body—the prolonged washing of the hands, for instance, or the moistening

of the conjunctiva of the eye and other mucous membranes with liquids not strong enough to injure the living cells of the skin. The best method of antiseptic treatment of the intestine, merely relative as its efficacy might be, was now recognised in the use of drugs which produced frequent and abundant evacuation.

How were we to square the conviction that so many of the microbes usually found in the body were injurious with the argument, drawn from the work of Darwin, that if our microbes are so dangerous they ought long ago to have been eliminated simply by the operation of natural selection? One observed constantly that not merely natural characteristics unfavourable to their possessor's life, but even organs which had merely ceased to be useful to him, disappeared more or less completely. To bring out more clearly this paradoxical aspect of the survival of our microbes, most of which were not merely useless but unquestionably injurious, he would draw attention to the fact that the very organs of the body which sustained this flora were themselves for the most part either useless or injurious to health and life. They would remember that the ducts of the capillary follicles in the skin were the seat of a microbian vegetation often composed largely of microbes capable of producing more or less serious disease. Well, those follicles were useless organs, and represented merely what was left of the hair that covered the skin of animals who were our ancestors. In the digestive apparatus of man, the part of the body richest in microbes, there were also to be found parts which, to say the least of them, were now useless. The vermiform appendix, for instance, was the remains of an organ which was more fully developed in our animal forefathers; in the anthropoid apes it was already found in the process of reduction. Even the stomach, that organ which might seem so indispensable for digestion and the normal existence of man, was in reality nothing but a large reservoir for food, a reservoir which could without serious inconvenience be dispensed with. There were at that moment four persons living without stomachs, and thus furnishing a strong argument against the utility of that organ.

Of all the parts of our digestive system it was certainly the small intestine alone that was indispensable to the continuance of life. And yet in man, who could support himself on food easily digestible, the small intestine was disproportionately fully developed. Instead of having it between 18 and 21 feet long, man might do with one-third of that length. Kukula reported a case in which he had removed almost two-thirds of the small intestine with the greatest advantage to the patient. In one case Körte had removed, together with part of the small intestine, the greater part of the large intestine, leaving only the terminal section. As a result of this operation the patient had been completely cured. He could cite other cases of successful surgical operations to prove the uselessness of the large intestine to human beings. In one case the whole of the large intestine had atrophied of itself, without operation, in consequence of a fistula, without interfering with the active life of the subject. The sum of all this was that we possessed a voluminous and highly developed organ, the large intestine, which fulfilled no useful function and bred a very copious and varied mass of microbes, capable of injuring us through their poisons.

In face of thisf act it remained to ask what the large intestine was, what its origin and the reason of its existence. The history of the capillary follicles was comparatively simple, for they were the surviving traces of hair which had protected from the cold the animals from which man was descended. The large intestine, on the contrary, was no mere relic, but an organ highly developed. It was, as a rule, found only in the mammiferous animals, and not in birds, reptiles, or others of the lower vertebrates. Dr. Metchnikoff went on to trace in some detail the development of the large intestine to the prevalence of certain special conditions in the life of herbivorous vertebrate animals capable of running at great speed, conditions no longer present in the life of their descendants, and no longer calling for the peculiar organisation developed to meet them. The slow tendency of evolution to bring about the atrophy of such organs or characteristics might, however, be assisted by medicine and surgery, medicine coping more effectually with the noxious microbes and their effects, while the progress of surgery had already brought it within its power to remove by operation organs or parts of organs propitious to the growth of the "flora."

Dr. Schunck proposed, and Prof. Hickson seconded, a vote of thanks to the lecturer, and the resolution was carried by acclamation.

MODERN METHODS OF GAS MANUFACTURE.

A PAPER on modern practice in the manufacture and distribution of illuminating gas was read by Mr. Harry E. Jones at the meeting of the Institution of Civil Engineers on April 16, and some of the points dealt with are here summarised.

The author remarked that improved returns from residuals at gasworks have been obtained by giving greater attention to the saving of fuel by the use of generator furnaces; by manufacturing the ammonia at the gas-works; by the preparation of cyanogen; and by the more extensive application of the antiseptics which are largely and cheaply produced from the tar.

The enrichment of gas, by reducing the return from residuals, has adversely affected the progress of gas-supply. The materials needed are all costly, and yield no return. Moreover, with incandescent burners, the cost of enrichment is wasted. Of the means of enrichment available, carburetted water-gas is preferred for cheapness and permanency. The advantages of this method are: facility for rapid and considerable addition to the output of gas, and for suspension of such additional supply without consequent expense; complete control of illuminating power over a wide range; avoidance of excessive accumulation of coke in winter; prevention of the deposit of naphthalene in the distributing mains and services, which formerly caused great loss and inconvenience; and reduction of space required by the plant, and for storage of materials. It was pointed out, however, that it is chiefly for mid-winter use, to relieve the strain on the coal-gas plant and the drain on the collieries, and to meet fogs and sudden climatic changes, that the system is profitable, as the price of oil advances with the price of coal, and to a figure that, having regard to value of residuals, cannot be paid without loss. During the winter of 1900–1901 the price of oil was practically prohibitive of its use, except for necessary enrichment or emergency use. Should it, however, be possible to supply unenriched water-gas, which, with the Welsbach burner, gives equal illuminating power, then the use of oil could be dispensed with and the combined coal- and water-gas processes could be carried on with a large saving and would enable the price of gas to be lowered by between 1*s*. 2*d*. and 1*s*. 8*d*. per 1000 cubic feet.

In purifying-plant the author recommended the abandonment of the old hydraulic seal, which is unstable, costly and very perishable. In his practice the entire cover is removable, being very light and held down by small bolts at the margin, and by bolts passing through both cover and floor and spaced at equal distances. The vessels are 8 feet deep and are arranged in groups of five worked in ordinary sequence, having both lime and oxide of iron in each. This system fulfils without nuisance all the requirements of the sulphur-purification demanded by the London Gas Referees without the cost, risk and space of the system of three separate groups previously necessary, in order, for carbonic acid, carbon bisulphide and sulphuretted hydrogen. For condensers the author prefers horizontal tubes, in which the tar and gas are cooled together, which have been found to remove naphthalene. Coke scrubbers are simplest and cheapest, and in practice more than secure the degree of purification from ammonia exacted by the London Gas Referees, and, by the ammonia retained, purifies the gas also from carbonic acid and sulphur. The residuals of gas are useful in purification, and a cycle of reactions was traced in the processes of manufacturing sulphate of ammonia by sulphuric acid made partly from the sulphur in the ammoniacal liquor and partly from that in the residual spent oxide of iron from purifiers.

The pressure for distribution of gas is usually 3 inches to 4 inches head of water, but Mr. C. C. Carpenter has for some time been delivering by means of Sturtevant fans, at pressures between 12 inches and 18 inches. In America distribution has been accomplished over long distances by employment of pressures of several pounds per square inch. Service pipes are now laid in steam-tubing 30 per cent. thicker than gas-tubing; they are coated with pitch before filling the ground in, and their life has thus been extended from 12 years or 14 years to more than 20 years. Meters of the "dry" form are now invariably employed, which, if examined periodically, at intervals of 6 or 8 years, can be maintained fairly accurate; by improvements in manufacture their life has been increased from 12 years to nearly 20 years.

THE FORMATION OF WAVE SURFACES IN SAND.[1]

ATTENTION was first called to tidal sand ripples by Prof. Osborne Reynolds,[2] who found them submerged in channels between sand banks in estuaries. My observations were on tidal sand ripples which I found above low water (Fig. 1). They are generally unsymmetrical in form, with the steep face on the sheltered side, as are "current marks" and æolian sand ripples. They apparently do not require for their formation any co-operation between flood and ebb currents, although where such co-operation occurs, the wave fronts probably become less sinuous. They are to be seen, not only in tidal estuaries, but also in some localities on the seashore[1] where the sands are exposed to waves as well as to currents, but they face with the current, not with the waves, and are thus readily distinguished from the wave-formed ripple mark. The smallest tidal sand ripples which I have found exposed at low tide were 3 feet from crest to crest, and all sizes from this to 20 feet wave-length are common. On a sand bank in the Dovey estuary (North Wales), opposite to the town of Aberdovey, I marked out a plot with stakes driven deeply into the sand, and recorded by daily measurements the increase, diminution and march of the sand waves. At neap tides the sands were nearly smooth, and as the tides increased the tidal sand ripples appeared, short and relatively steep. The amplitude increased steadily, the average wave-length also increased, apparently by elimination of some of the ridges. When the highest spring tide was passed the amplitude rapidly diminished, the wave-length remaining nearly, but not quite, constant, and the mean sand level remaining practically unchanged. Details of the measurements will be given in the *Geographical Journal*. The circumstances favourable to the formation and preservation of tidal sand ripples above low-water mark are, gentle current at first of the flood and last of the ebb, and strong current when the water is deep over the sands. I have often watched the course of events when the last of the ebb has been running over the ridges. The process is then one of decay, not of growth, the sand being swept from the crests into the troughs. What goes on during the *growth* of the ridges? Let the depth of water be sufficient; then, if the velocity of the current be small, the sand grains roll and slide along the bottom, but, as the speed increases, the water, almost suddenly, becomes highly charged with sand in "eddying suspension." A uniform current flowing swiftly over extensive sands picks up as much sand as it drops, thus causing a drift of sand which on the whole is uniform, neither raising nor lowering the bed.[2] My observations indicate, however, that *in detail* the drift is not uniform, but attended by alternate silt and scour along lines at right angles to the current and equidistant from one another, the surface of the sand bank being thus carved into transverse ridge and furrow without change of mean level. The slightest convexity of surface causes a convergence of currents, a concavity a divergence, and, under the conditions specified, deposition occurs upon the convexities, whilst the concavities are scoured. The vertical inequalities are thus increased,[3] and it is easy to see that the ridges will extend themselves laterally.[4] Thus the ridge and furrow inevitably form and grow. What, then, are the limits of this growth? Obviously the depth of water is one limit. When the cross section of the stream above the sand ridge is reduced by a certain amount, the greater force of water there

FIG. 1.—Tidal sand ridges in the Dovey estuary. Photograph taken June 15, 1900. Wave-lengths about 15 feet.

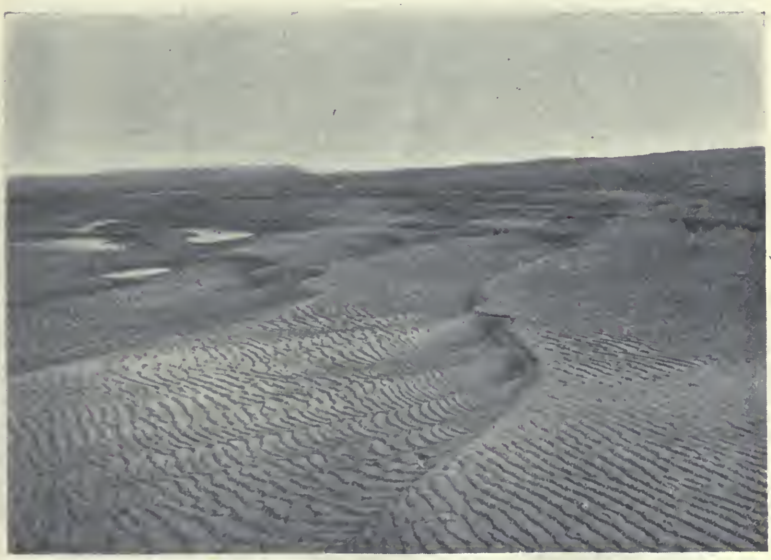

FIG. 2.—Current mark upon tidal sand ridges. Photograph taken June 15, 1900, in the Dovey estuary.

removes the sand as quickly as it is brought, and further growth is thus stopped. If the depth be further reduced, *e.g.* during an ebbing tide, the ridges decay. In deep water the height of the ridges is limited to that at which the velocity of the stream can maintain an active eddy on the lee of the ridge, and if the velocity be reduced the troughs silt up owing to the sand falling into dead water. It is probable, also, that the amplitude is sometimes restricted by the velocity of the current surpassing the limit suitable to the fineness or lightness of the material of which the ridges are composed. For it is evident that there is a difference between the pressure upon the weather side and upon the lee side of a ridge. I notice when wading on sand banks ridged with tidal sand ripples that the pressure of one's tread often causes a bodily sliding of the sand from trough to crest. The growth and even the maintenance of the ripples demands a *differential* movement of the material. There must be a part to stand fast as well as a part to be redistributed. Thus a moderate range in the sizes of the particles of the loose granular material is favourable to the formation and retention of a wavy surface through a considerable range of velocity of the inducing fluid. It is evident that two sets of crossing ridges cannot be simultaneously produced by true current action, and, in fact, crossing tidal sand ripples are seldom seen. Sometimes, when the direction of current has suddenly changed at a particular time of tide, two sets of ridges are successively formed. The "tidal sand ripples" seem, in fact, to be true current-formed sand waves. They are themselves rippled over with "current mark," which is more properly a ripple, in that (like capillary ripples) it only goes skin-deep (Fig. 2). It seems to be due rather to the pulsations of a current than to the current as such. I have often seen little sand ripples in fairly deep rapid streams, which I suppose would properly be called current mark, facing obliquely or transversely to the direction in which the sand was travelling. This was near the shore where the most marked pulsation was shorewards.

I have described elsewhere[1] some little dunes formed by the wind out of the very fine and light sand of the dry Nile bed, when the river was at its lowest. These dunes, which in size and shape somewhat resembled tidal sand ridges, were covered with a beautiful tracery of little ripples. In the formation of the æolian sand ripples the heterogeneity of the sand plays a much more important, the pulsation of the fluid a much less important, part than in the case of the current mark of streams. I have one more observation on this point to add to those already published. I noticed, during strong winds lasting several days, at Montrose, N.B., March 1900, that the rippling of the remarkably uniform dry drifting sand was very slow in beginning. As soon, however, as there was a fair supply of the coarser kind of sand grains aggregated together, the rippling action went on vigorously and rapidly. A moderate range of sizes of material, *e.g.* fine sand and coarse sand, is best for æolian rippling. In the vicinity of big stones the scour of the wind is too great. During the occasions on which I visited this little dune tract the strong breeze drifted the fine light sand thickly near the surface, and in the afternoons there was a haze of flying sand extending 20–30 feet above the foreland. The conditions were, in fact, very similar to those with which I have since become familiar in the case of formation of tidal sand ripples. It seems highly probable that the fine, light sand in this wind was in a condition similar to the "eddying suspension" of water drift, proceeding in the manner described by Osborne Reynolds, plus the rapid increase of slight inequalities forming waves, as above described. The same brisk breezes which were forming dunes as regular trains of sand waves, as high as the quantity of dry Nile sand permitted, were not able to deal in the same free fashion with the coarse quartz sand of the larger desert dunes west nd east of the Delta.

FIG. 3.—Rippled clouds. Photograph taken August 5, 1900, near Bournemouth, 5.15 p.m., looking S.

FIG. 4.—The true aërial ripple mark. This is the negative of Fig. 3, and shows the ridges of still air between the whirling air of the clouds.

[1] "On Desert Sand Dunes Bordering the Nile Delta."—*Geogr. Journ.* January 1900.

Note on Photographing Aërial Ripple Mark.

Fig. 3 is reproduced from a photograph which I took of some remarkable ripple clouds near Bournemouth, on August 5, 1900, at about 5.15 p.m. The camera was pointed south; the sun, of course, is on the right, and the shadow of each cloud can be seen on the right-hand edge of the next one. These clouds were drifting rapidly to the east (left), the breeze at the ground level blowing towards the same direction. Ruskin wrote[1] long since of vapour "falling into ripples like sand." The general likeness is indeed striking, but the differences of detail are also noticeable, which is not to be wondered at, seeing that the cloud ripples are not the counterpart of the rippled sand, but of the whirling water between the sand ridges. How then shall we see the form of the aërial ripple mark where there is only blue sky? Simply by reproducing our photograph as a negative (Fig. 4). With this compare Fig. 5, an ordinary (positive) view of the wave-formed ripple mark of the strand, taken at Montrose, N.B., March 1900. Note the similarity of the sharp-topped ridges of still air, between the revolving cores where the clouds are, to the knife-edged ridges of the sand. But most remarkable of all is the precise correspondence of the confluence of ridges, wherever the wave-length of the ripple mark is about to change *per saltum* (for the wave-length of ripple mark increases in "multiple proportion," three ridges merging into two). And here our sky photographs are superior to, and throw light upon, our sand ripple mark photograph, for the latter had to be taken when the rippling action had ceased and the troughs were no longer filled with whirling water. Fig. 3, however, indicates what is going on where the ripple ridges are being merged, for the lights and shadows of the cloud indicate the activities of the working parts of the system. The rippled cloud here photographed, and consequently the true air ripples also, are symmetrical. This is not always the case; the clouds are often opaque (thick) at one edge and transparent (thin) at the other. In this case the form of the aërial ripple mark must be more like that of current mark, of æolian sand ripples and of tidal sand ripples. The likeness between cloud negative and sand ripple positive would be more striking but for the circumstance that we look up at the clouds and down at the sand. This makes the perspective different in the two. The real resemblance is best seen when separate prints are handled, one or other of which being inverted the perspective becomes similar in both.

Fig. 5.—Ripple mark of the strand. Photograph taken at Montrose, N.B., March 10, 1900.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Cambridge.—A meeting of members of the Senate and others interested in the proposal to make some acknowledgment to Prof. Liveing for his valuable services to science and to the University will be held in the combination room of St. John's College on Saturday next, April 27, at 2.30 p.m.

Mr. Randolph Morgan, of Philadelphia, has given the sum of 200,000 dollars to the University of Pennsylvania for a new physical laboratory.

From the Catalogue of the University of Cincinnati, for 1900–1901, we see that the total endowment of the University amounts to 3,357,308 dollars, or nearly 700,000*l*. The latest large donation was in the year 1899, when Mr. David Sinton gave the University 100,000 dollars upon the condition that the income derived therefrom should be used in maintaining the Academic Department. The University has an observatory well equipped for carrying on astronomical work The observatory is at the present time co-operating with the International Geodetic Association in the determination of the variation of latitude.

Lord Curzon, Viceroy of India, visited on Tuesday the Mahomedan Anglo-Oriental College, which was founded at Aligarh by Sir Syed Ahmad in 1875 with the view of affording Mahomedan youths an opportunity of gaining a first-class education under English professors. A marked success has since been obtained, the Nizam and all the Mahomedan notables affording liberal support. Alluding to the desire of Mr. Beck, the late principal, who devoted his life to the College, to expand the institution into a residential University, the *Times* reports Lord Curzon to have said that the project had reached the ears of the late Queen, who inquired most sympathetically about it. Lord Curzon warned his hearers that they would never get from a University consisting of little but examining boards that lofty ideal of education, the sustained purpose and the spirit of personal devotion associated with the historic Universities of England, and also produced in some measure by the ancient Universities of Islam.

The reality of the competition between School Board classes and Technical Institutions in some places is clearly exemplified by the following extract, from the latest Report of the Governing Body of the Goldsmiths' Institute, New Cross—in every respect an excellent institution, where thorough instruction is given in science and technology. "The Governors in their last Report drew attention to the decline in the number of students attending certain classes. This decline began in 1898 (down to that year the class entries had been uniformly progressive), and was mainly due to the extension of the Free Evening Continuation Schools of the London School Board, and particularly to certain special centres which have been opened close to the Institute. It will be sufficient on the present occasion to state that the same causes still operate to check the natural growth of the classes affected." Reference has been made (p. 553) to the recent decision in the Court of Appeal that School Boards cannot legally support classes of this character or science schools out of the rates, but it has not yet been decided whether this ruling will be accepted. The foregoing extract emphasises the necessity for finally deciding upon the scope or area of influence of the various educational authorities, and so giving our educational system an organic structure in which each part has clearly defined work to do.

A meeting of the Agricultural Education Committee was held on Tuesday, Sir William Hart Dyke presiding. The executive committee reported that the two subjects most urgently requiring

attention at the present moment were:—(1) The union or co-ordination of the work of the Board of Education and the Board of Agriculture in dealing with agricultural and rural instruction; and (2) the training of teachers in nature knowledge and other rural subjects. Speaking upon the first of these subjects, Mr. Hobhouse, M.P., said the Board of Agriculture only inspected certain of the higher agricultural schools, and did not systematically advise or report on the work of the local authorities. It had no voice in drawing up schemes for agricultural instruction for which grants were given under the Directory or Code. It thus failed to take the position assumed by the agricultural departments of nearly every other country, including Ireland and our own colonies, where the progress of agriculture was systematically promoted by encouraging the best methods of instruction. The yearly sum devoted to agricultural instruction and research in the United States was (federal grants only) 700,000*l.*; in Canada, 156,000*l.*; in France, 152,460*l.*; and in Würtemberg, 65,000*l.*; while in England the sum was only about 15,000*l.* It would seem that the example of Scotland should be followed in England, and that the educational powers of the Board of Agriculture should be transferred to the Board of Education, especially as under the Board of Education Act, 1899, there already existed power to make a similar transfer by Order in Council. The Board of Agriculture would then, much to its own relief, cease to be an educational authority, though it might, perhaps, retain some supervision over certain experimental work carried on by agricultural societies.

SCIENTIFIC SERIALS.

American Journal of Science, April.—The magnetic theory of the solar corona, by F. H. Bigelow. A discussion of an experiment of Ebert on the behaviour of an electrified sphere in a magnetic field, when placed in a rarefied gas. The phenomena observed in the corona of the sun agree in a remarkable way with the effects produced in the above experiment.—Tertiary springs of Western Kansas and Oklahoma, by C. N. Gould.—Some fundamental propositions in the theory of elasticity. A study of primary or self-balancing stresses, by F. H. Cilley. A discussion of the effects of initial or "primary" strain of a body upon its elasticity. Since these strains and stresses are a component of the actual strains and stresses existing in substances, it is concluded that the latter cannot be defined through the equations of elasticity alone.—The boiling point of liquid hydrogen determined by the hydrogen and helium gas thermometers, by T. Dewar. From the *Proceedings* of the Royal Society.—On the nature of vowels, by E. W. Scripture. Reproductions of a magnified set of curves from a gramophone. The results tend to show that the movement of the air in the mouth cavity is a free vibration and not a forced one. The cord movements in the vowels are of the nature of explosive openings and not of the usual vibratory form found in most musical instruments.—Note on the behaviour of the phosphorus emanation in spherical condensers, by C. Barus.—The remarkable concretions of Ottawa County, Kansas, by W. T. Bell.

Annalen der Physik, April 1.—The application of the method of residual rays to the proof of the law of radiation, by H. Rubens and F. Kurlbaum. A discussion of the various expressions which have been proposed to show the relations between the intensity of radiation, the wave length and the temperature. A detailed account of the experimental methods is given, measurements being carried out at temperatures between $-180°$ C. and $1450°$ C., a graphical comparison being given between the experimental results and those calculated from the formulæ proposed by Wien, Thiesen, Rayleigh and Planck. The simple formula of Planck would appear to be the best hitherto proposed.—The elementary laws of electrodynamics, by E. Wiechert.—On the absorption of heat by carbonic acid, by S. Arrhenius. An account of the results of measurements of the absorptive capacity for heat of carbonic acid. The results are applied to the discussion of the effects of carbonic acid in the atmosphere upon the temperature of the air.—On the surface tension of water surfaces covered with an oil layer, and on the range of molecular action, by R. H. Weber. The value deduced from the experiments for the radius of molecular action is 115 $\mu\mu$., considerably greater than that deduced from the experiments of Reinold and Rucker, 10 to 17 $\mu\mu$.—On the phenomena in induction coils, by K. R. Johnson.—Mechanical vibrations of an isolated stretched wire with visible electrical discharges, by O. Viol. If an isolated stretched wire is charged from one end with electricity at high potential, transverse vibrations are set up in the wire, and if the electricity is negative and the charge sufficiently high for a visible discharge to take place along the wire, only the nodes appear to shine.—On the mode of action of coherers, by K. E. Guthe.—Contribution to the knowledge of the thermomagnetic longitudinal effect, by L. Lownds.—On the band spectra of alumina and nitrogen, by G. Berndt.—On the change of the absorption of light in solid bodies with the temperature, by J. Kœnigsberger.—On the influence of a resistance free from self-induction on the oscillatory discharge of a condenser, by T. Mizuno.—The air barometer, by H. A. Naber.—On the spectrum equation of polished platinum, by D. A. Goldhammer.—On the pressure of light rays, by D. A. Goldhammer.—On the magnetism of iron, by C. Fromme.

SOCIETIES AND ACADEMIES.

LONDON.

Chemical Society, March 21.—Prof. Thorpe, president, in the chair.—The following papers were read:—Researches on morphine, part ii., by S. B. Schryver and F. H. Lees. The authors have previously shown that bromomorphide is decomposed by water with formation of isomorphine, a base isomeric with morphine; it is now shown that another isomeride, β-isomorphine, is also produced in small quantity. Phosphorus trichloride converts codeine into chlorocodeide, which corresponds with bromomorphide and is convertible into isocodeine, a base isomeric with codeine.—The constitution of pilocarpine, part ii., by H. A. D. Jowett. Bromine acts upon isopilocarpine with formation of dibromoisopilocarpine perbromide and small quantities of monobromoisopilocarpine and isopilocarpinic acid; the latter is an oil of the composition $C_{11}H_{16}O_4N_2$. On oxidising dibromoisopilocarpine with permanganate, pilopinic acid, $C_8H_{11}O_4N$, and pilopic acid, $C_7H_{10}O_4$, are obtained. At 100°, in presence of water, bromine acts on isopilocarpine with production of dibromoisopilocarpinic, monobromoisopilocarpinic, bromopilopinic and bromopilopic acids.—The chemical action of *Bacillus coli communis* and similar organisms on carbohydrates and allied compounds, by A. Harden. The author has examined the products of the action of *B. coli communis* and *B. typhosus* on carbohydrates, and notes that the production of alcohol by the former organism appears to depend on the presence of the group $CH_2(OH)\cdot CH.OH$ in the compound to be fermented.—Action of dry silver oxide and ethyl iodide on benzoylacetic ester, deoxybenzoin and benzyl cyanide, by G. D. Lander.—Alkylation of acylarylamines, by G. D. Lander. Dry silver oxide and ethyl iodide convert the acylarylamines into the imino-ether, whilst if methyl iodide is substituted for ethyl iodide, a mixture of the imino-ether and the acylalkylamine usually results.—The preparation of aliphatic imino-ethers from amides, by G. D. Lander.—Note on the latent heats of evaporation of liquids, by H. Crompton.—On the atomic weight of lanthanum and on the error of the "sulphate method" for the determination of the "equivalent" of the rare earths, by B. Brauner and F. Pavlíček. It is shown that in the conversion of lanthanum oxide into sulphate for atomic weight determinations, small quantities of acid sulphate are produced and cause error in the determination of the equivalent; it is further shown that lanthanum, as hitherto known, is a mixture of two earth metals in which the true lanthanum of atomic weight 139·0 predominates.—On the atomic weight of praseodymium, by B. Brauner. The author has determined the atomic weight of praseodymium by four methods and made ebullioscopic determinations with the chloride in alcohol solutions; the final atomic weight of praseodymium is given as 140·94.—On praseodymium tetroxide and peroxide, by B. Brauner. Praseodymium tetroxide, Pr_2O_4, is obtained as a black powder, by fusing the nitrate with nitre and on treating praseodymium nitrate with hydrogen peroxide the hydrate of praseodymium peroxide, Pr_2O_5, is produced.—Note on neodymium, by B. Brauner. The number 143·5 was found by the sulphate method for the atomic weight of neodymium; this metal gives a tetroxide, Nd_2O_4, and a peroxide, Nd_2O_5.—Contribution to the chemistry of thorium, by B. Brauner. The author concludes that thorium does not consist of a single element because on fractional hydrolysis of ammonium thorium oxalate, fractions are obtained in which the

atomic weight of the metal varies from 220 to 232.—Pheno-α-ketoheptamethylene and its derivatives, by F. S. Kipping and A. E. Hunter. Pheno-α-ketoheptamethylene is obtained by the action of aluminium chloride on phenylvaleric chloride; its oxime is reducible to pheno-α-aminoheptamethylene,

$$C_6H_4\left\langle\begin{array}{l}CH_2.CH_2.CH_2\\ \qquad\qquad\quad |\\ CH(NH_2).CH_2\end{array}\right.$$

—Note on diphenyldinitroethylene, by J. J. Sudborough.—Para- and ortho-cyanohydroxy-derivatives of pyridine, by J. Moir.

Geological Society, April 3.—Mr. Horace W. Monckton, vice-president, in the chair.—The igneous rocks and associated sedimentary beds of the Tortworth inlier, by Prof. C. Lloyd Morgan, F.R.S. and Mr. S. H. Reynolds. It has long been known that igneous rocks occur in the district under consideration, but opinions are divided as to their intrusive or contemporaneous character. Evidence is here brought forward to show that the igneous rocks form two bands, the lower interbedded with Upper Llandovery strata, and the upper overlain by Wenlock, and that both bands are probably contemporaneous lavas. The microscopic examination of the lower igneous rock shows that it is a basaltic andesite containing plagioclase (acid andesine or oligoclase), pseudomorphs after enstatite, with chloritic and iron-oxide patches. The higher bed sometimes contains fresh augite, and both bands frequently contain rounded grains of quartz. In other examples the felspars appear in three forms, with augite and enstatite, and the rock ranges from an andesite to a porphyritic basalt. The quartz-grains present appear to be xenoliths. The silica-percentage of the rocks on a moisture-free basis varies from 61 to 67, while the specific gravities are from 2·74 to 2·99.

Linnean Society, April 4.—Mr. C. B. Clarke, F.R.S., vice-president, in the chair.—The secretary exhibited some British species of plants forwarded by M. Buysman, of Middelburg, to show the character of a proposed issue to include the whole of the British flora, on which some remarks were made by the chairman and Mr. James Groves.—Mr. W. B. Hemsley, F.R.S., exhibited specimens of Sapium and Hevea (Euphorbiaceæ) and Castilloa (Artocarpaceæ), with a view to clear up certain questions concerning the rubber-trees, by examining a large series of plants and seeds forwarded by Mr. Jenman, Government botanist in British Guiana. The genus Hevea included ten or a dozen described species inhabiting eastern tropical South America, but none in the West Indies. *Hevea brasiliensis*, the source of the true Pará rubber, was not very different from *Hevea guianensis*, which is restricted to French Guiana, the differences between them being shown in the figures given of the floral structure and seeds in Hooker's *Icones Plantarum*, plates 2570-2577. It was formerly supposed that two species of Hevea might be distinguished in British Guiana, one (*Hevea pauciflora*) having thin leaves and a hairy ovary, the other thick coriaceous leaves and a glabrous ovary; but after examining a large number of specimens, Mr. Hemsley had come to the conclusion that the differences were not constant, and that all the specimens exhibited might belong to one species, and merely represented individual variation. The exhibition demonstrated the difficulty of determining species of Hevea from imperfect specimens, and especially from seeds alone.—A paper was read by Messrs. W. B. Hemsley and H. H. Pearson on a small collection of dried plants made by Sir Martin Conway in the Bolivian Andes in 1898–99. This collection contained but forty-six species, but these were of special interest from the great height at which they were found, *i.e.* between 18,000 feet and 18,700 feet above sea-level. The highest Andine plants on record were stated to be *Malvastrum flabellatum*, Wedd., and a grass, *Deyeuxia glacialis*, Wedd.—A paper was read by Mr. G. S. West on some British freshwater Rhizopods and Heliozoa. When collecting freshwater algæ in different parts of the country the author had found Rhizopods and Heliozoa in abundance, and had preserved them for future examination. The observations now made related to their habits and structure, and comprised descriptions of peculiar forms of some of the commoner types, as well as remarks on several little-known species. Half a dozen species were described as new, and one (*Leptochlamys ampullacea*) was referred to a new genus. Two points of special interest were (1) the presence of a perforation at the apex of the shell in some forms of *Difflugia acuminata*, the shell thus possessing two openings: and (2) the possession of certain characters by members of the genus Vampyrella which sharply demarcate them from other Rhizopods. In the latter case, Mr. West had been able to observe several of these minute creatures feeding on the cell-contents of a species of Mougeotia.

Mathematical Society, Thursday, April 11.—Dr. Hobson, F.R.S., president, in the chair.—Mr. A. B. Basset, F.R.S., made a brief communication on the projective properties of cubic and quartic curves. Prof. Love, F.R.S., also made a few remarks on the communication.—A paper by Dr. F. Morley, entitled "Summation of the Series

$$\sum_{n=0}^{\infty}\Gamma^3(a+n)/\Gamma^3(1+n),"$$

was communicated by its title.—Lieut.-Colonel Cunningham, R.E., announced the factorisation of the algebraic prime factors of $5^{75}-1$ and of $5^{105}-1$.
The first =

151.3301. 183794551. 99244414459501,

and the second =

21226783250214361. 207468970805907721.

He has not determined the composition of the three large factors.

Zoological Society, April 16.—Mr. Howard Saunders, vice-president, in the chair.—A communication was read from Mr. W. L. Distant entitled, "A Revision of the Insects of the Order Rhynchota belonging to the Family Coreidæ in the Hope collection at Oxford." It was stated to be supplementary to the paper on the same subject already published in the *Proceedings* (*cf.* P.Z.S. 1900, p. 807)—Mr. F. E. Beddard, F.R.S., read a series of notes on earthworms, which comprised (1) an account of some earthworms from eastern tropical Africa in the collection of the British Museum; (2) a note on the spermatophores of *Polytoreutus*; (3) a note on the spermatophores of *Stuhlmannia*; (4) remarks on the ovaries, oviducts and spermducts of *Stuhlmannia*; and (5) a contribution to our knowledge of the genus *Gordiodrilus*.—Mr. F. E. Beddard also read a paper on the anatomy and systematic position of the open-billed stork (*Anastomus oscitans*), based on an examination of a specimen of this bird that had died in the Society's gardens. The author was of opinion that the structural differences between *Anastomus* and the typical storks were so slight that they did not warrant the placing of this bird in a separate family or subfamily.—A paper was read from Dr. H. Lyster Jameson giving an account of the mother-of-pearl oysters (*Margaritiferae*). It was based upon a study of the series of these oysters in the British Museum and upon an examination of a large series of marketable mother-of-pearl oysters of various species in the London shell-warehouses, and dealt with the specific identity, geographical distribution, local variation, original name and synonymy of the different members of *Margaritifera*. The subgenus was divided into two sections, characterised respectively by the absence or presence of rudimentary hinge-teeth. Several new species and local forms were described in this paper.—A communication from Miss Emily M. Sharpe contained a list of the Lepidoptera collected by Mr. Ewart S. Grogan during his expedition from the Cape to Cairo. The names of sixty-six species represented in the collection were enumerated in the paper. Two of these were described as new under the names *Amauris grogani* and *Gnophodes grogani*.

Royal Astronomical Society, April 12.—Prof. Turner read a paper by Mr. H. C. Plummer on a method for mechanically compensating the rotation of the field of a siderostat. Prof. Turner had in a previous paper given the principle of several methods by which this might be effected, but Mr. Plummer's appeared a still simpler arrangement. Prof. Turner gave an account of his own paper—Tables and Formulæ for connecting the Co-ordinates of Stars on different Photographic Plates—particularly in connection with the Astrographic Chart of the Heavens.—Mr. Bryant read a further investigation on the "two method" personal equation, in which he brought forward many interesting points in connection with the changes in the personal equation of three different observers at the Royal Observatory, Greenwich.—Mr. McClean read a paper on the spectrum of Nova Persei, and showed photographs, in which its spectrum was compared with those of η Argûs and Nova Normæ, Father

Sidgreaves had sent a communication in which the Nova was considered as a variable star with a variable spectrum.—Mr. Whittaker read some observations by Mr. Sharp of the changes of brightness in the Nova, and Dr. Rambaut read the observations made at the Radcliffe Observatory, Oxford. It appeared from these that while the light of the new star was steadily diminishing there had been fluctuations of brightness to the extent of about a magnitude and a half. Minima had been observed on March 22, 25, 28, 31, also on April 3 and 6. The latter minimum was prolonged to April 7, after which the light increased, and again diminished.—Papers by Mr. Innes on anomalous occultations of stars by the moon, and by Mr. Denning on meteoric showers from the region between α and β Persei were also read.

Paris.

Academy of Sciences, April 15.—M. Fouqué in the chair.—New researches on the action of hydrogen peroxide upon silver oxide, by M. Berthelot. The action of hydrogen peroxide upon silver oxide is regarded by the author as first resulting in the formation of an unstable silver peroxide, which then decomposes in two ways, partly into silver and oxygen, and partly enters into combination with some of the unchanged silver oxide present, giving an oxide Ag_4O_3.—On the representative power of a finite portion of a continuous curve, by M. G. Lippmann.—On the decomposition of meromorphic functions into simple elements, by M. Émile Borel.—On the roots of transcendental equations, by M. Edmond Maillet.—On the continued fraction of Stieltjes, by M. H. Padé.—On groups of operations, by M. G. A. Miller.—Action of the radium radiation upon selenium, by M. Eugène Bloch. A selenium cell submitted to the action of the radium rays undergoes a diminution of resistance of the same character as that produced by light or by the Röntgen rays, except that the effect is more slowly produced and that its magnitude is smaller. These experiments form an argument in favour of the idea that the radium rays are formed of a complex of kathode rays and of Röntgen rays.—Disruptive discharge in electrolytes, by MM. André Broca and Turchini. It is shown that the conductivity of electrolytes requires a certain time for its establishment, and that for sufficiently high frequencies electrolytes are pure dielectrics. This is in accordance with the requirements of the electro-magnetic theory of light.—On oscillating sparks, by M. G. A. Hemsalech.—The detection of alkaloids by the micro-chemical method, by M. E. Pozzi-Escot. The use of picric acid as a micro-chemical reagent for alkaloids, suggested by M. Popoff, is not found to form a trustworthy method, the only really characteristic crystals being given by strychnine.—On the flora of mosses in caverns, by MM. L. Géneau de Lamarlière and J. Maheu.—On the rational pruning of ligneous plants, by M. F. Kövessi.—On the probable existence of a recent sea in the region of Timbuctoo, by M. Aug. Chevalier.

DIARY OF SOCIETIES.

THURSDAY, April 25.

Royal Institution, at 3.—Naturalism in Italian Painting: Roger Fry.
Institution of Civil Engineers, at 8.—"James Forrest" Lecture—On Chemistry in its Relations to Engineering: Prof. Frank Clowes.

FRIDAY, April 26.

Royal Institution, at 9.—Colour in the Amphibia: Dr. Hans Gadow, F.R.S.
Society of Arts, at 8.—Polyphase Electric Working: Alfred C. Eborall.
Physical Society, at 5.—On the Thermodynamical Correction of the Gas Thermometer: Prof. Callendar, F.R.S.—On the Production of a Bright-line Spectrum by Anomalous Dispersion and its Application to the Flash-Spectrum: Prof. R. W. Wood.
Institution of Civil Engineers, at 4.—Repetition of "James Forrest" Lecture—On Chemistry in its Relations to Engineering: Prof. F. Clowes.

SATURDAY, April 27.

Royal Institution, at 3.—Climate: its Causes and its Effects: J. Y. Buchanan, F.R.S.

MONDAY, April 29.

Royal Geographical Society, at 8.30.—Travels in Central Kurdistan: Major F. R. Maunsell.
Society of Arts, at 8.—Alloys: Sir W. C. Roberts-Austen, K.C.B., F.R.S.
Institute of Actuaries, at 5.30.—On the Valuation of Staff Pension Funds: H. W. Manly. With Tables and Examples by E. C. Thomas.

TUESDAY, April 30.

Royal Institution, at 3.—Cellular Physiology: Dr. A. Macfadyen.
Society of Arts, at 4.30.—The British West Indies: Sir Nevile Lubbock, K.C.M.G.
Institution of Civil Engineers, at 8.—Annual General Meeting.

WEDNESDAY, May 1.

Society of Arts, at 8.—The Thames Steamboat Service: Arnold F Hills.
Entomological Society, at 8.—The Metamorphoses of *Æschna cyanea*, illustrated by Photographs taken from Life: Frederick Enock.—The Classification of a New family of the Lepidoptera: Sir George F. Hampson, Bart.
Society of Public Analysts, at 8.—Alkaline Waters from the Chalk: W. W. Fisher.—Citron Oil: Herbert E. Burgess.—Arsenic in Coal and Coke: Alfred C. Chapman.

THURSDAY, May 2.

Royal Society, at 4.30.
Linnean Society, at 8.—Studies in Heterogenesis: Prof. H. C. Bastian, F.R.S.
Chemical Society, at 8.—The Synthetical Formation of Bridged-Rings Part I. Some Derivatives of Bicyclopentane: Prof. W. H. Perkin, jun., F.R.S., and Dr J. F. Thorpe.—Ballot for the Election of Fellows.
Institution of Electrical Engineers, at 8.—An Instrument for Measuring the Permeability of Iron and Steel: C. G. Lamb and Miles Walker.—A Watt-Hour Meter: Frank Holden.

FRIDAY, May 3

Royal Institution, at 9.—Memory: C. Mercier.
Society of Arts, at 8.—Polyphase Electric Working: A. C. Eborall.
Anatomical Society, at 4.—(*a*) Additional Notes on the Articulations between the Occipital Bone, Atlas, and Axis in the Mammalia: (*b*) On the Development of Digits in Cetacea; (*c*) Observations on the Development of the Human Brain before and after Birth: Prof. Symington.—A Contribution to the Study of the Morphology of Adipose Tissue: Dr. H. Batty Shaw.—A Lantern Demonstration showing the Origin and Nature of the Hydatiform Bodies of the Testicle and Broad Ligament, with Special Reference to the Fate of the Mullerian Duct in the Epididymis: J. H. Watson.—Relation of Structure to Function, as illustrated by the Growth of the Inferior Femoral Epiphysis: Prof. Arthur Thomson.

SATURDAY, May 4.

Royal Institution, at 3.—Climate: its Causes and its Effects: J. Y. Buchanan, F.R.S.

CONTENTS.

SUPPLEMENT TO "NATURE."

DARWINISM AND STATECRAFT.

National Life from the Standpoint of Science. An Address delivered at Newcastle, November 19, 1900, by Karl Pearson, F.R.S. Pp. 62. (London: A. and C. Black, 1901.)

THE main purpose of this address is one which all thinking men, who desire the good of their fellow men, must respect, and many will heartily approve. Prof. Pearson presses upon his readers the importance to a nation of the possession by its constituent individuals of good strong brains as well as of good strong muscles, and of a well-directed training of those brains. He points out that the laws of heredity are as true for mankind as for farm stock or pigeons, yet that the result of modern civilisation is to remove or suspend the natural selection by which, in the case of non-social organisms, those individuals with inferior qualities would be prevented from obtaining success in the struggle for existence, and so hindered from largely contributing to the reproduction of the race. He points out that, on the contrary, accumulated wealth enables its inheritors to produce and rear large families without regard to the qualities of the inheritor, and that what seems to be a still more dangerous condition arises from the reckless and abundant breeding of the hopelessly poor and unsuccessful members of the community. The class which has the greatest mental endowment and is serving the nation best in all directions, marries late and produces few children. Deliberate selection in breeding and the restriction of the increase of worthless stock would, if such discrimination were within our limits of knowledge, produce definite results in mankind as it does in animals. But, in common with many other thinkers who have examined this question, Prof. Pearson does not see the way to any control of the reproductive function in civilised communities, though he does not seem to doubt, as I should do, that mankind would conduct these breeding operations with real success were the control to be tolerated. Where custom has introduced a system of restricting the size of families, as in France, Prof. Pearson tells us that unforeseen results follow, as, for instance, the relatively excessive increase of some section or racial division of the community which refuses to adopt the custom of producing only two children. The population of France, it is said, is becoming more and more largely composed of Breton stock in consequence of the production of large families by that race, whilst the rest of the population deliberately restricts itself. Prof. Pearson does not urge any attempt on the part of the community to interfere with the individual in this matter. It is, indeed, a matter which requires far deeper study than Prof. Pearson or any one else has yet given to it before conclusions worthy of the name of science, and so well founded as to justify practical measures, can be formulated.

On the other hand, in advocating a really wise and carefully considered *training* of such brains as the mixed stock of the community presents for manipulation, Prof. Pearson is on less doubtful ground. He justly points out that not only in our warfare in South Africa, but in commerce and manufacture, we stand in need of trained "scouts," men who have learnt to keep their eyes open and apply common sense, men *trained to observe and reason.* Our educational system fails to train the youth of the country in this way; it does not even aim at it or consider it. Training in what is called "natural science" or in scientific method is utterly neglected. As I have shown elsewhere, Oxford sets the example of neglect, and, naturally enough, that example is followed by each successively lower grade of school throughout the Empire. Prof. Pearson rightly insists that it is not mere knowledge of scientific results and formulæ which is needed, but the training which a proper study of a branch of science can give. The British parent foolishly and mistakenly says, "I want my son to learn what will be useful to him in his profession in life." Prof. Pearson has heard it over and over again in his capacity as a teacher, and I can, with a similar range of experience, fully confirm him. Never, says Prof. Pearson, does the British parent say, as he ought to say, "I want my son to know how to observe and how to think." The result of this almost universal misapprehension of the value and purpose of education is that where, after prolonged resistance, science has been forced into colleges and schools, it is perverted and degraded by the commercial purveyors of so-called education; it is represented by scraps of information supposed to be useful in engineering, brewing or medicine. Meanwhile the claim is openly made on behalf of the "humanities" (classical literature, philosophy and history) that they alone can give the training of the mind which is desirable over and above mere technical information.

It cannot, I think, be denied that this false issue has been raised by the advocates of the present antiquated course of study through which the average youth of England is slowly and fruitlessly dragged at Oxford and the great schools of the country. Partly through ignorance, partly through interest, here as in other great mechanisms which affect the welfare and the destiny of the British nation, a traditional, ill-considered procedure and a fruitless expenditure of power and opportunity are obstinately maintained and ruthlessly defended by those who find the present arrangements profitable to themselves and their class. With persistence, which is the index of either profound ignorance or overweening conceit, science is declared to be what it is not, namely, professional or technical information, and then it is asserted that science is useless as "training," and that "training" can be given by the traditional classical studies alone. The value of real education in science, namely, its training of men to observe and to reason, does not, of course, belong to the travesty of science, which is all that the educational ring of schoolmasters and college tutors have allowed to grow up in the system which they control. Prof. Pearson has my sympathy in his endeavour to persuade our fellow-countrymen that training in science is a necessary and vital factor in national prosperity, and that it is almost totally unprovided for in this country.

But I greatly fear that this is a case in which it is useless to address the democracy. It is waste of words to harangue the deaf; it is foolish to appeal to the eyes

of the blind. Germany did not acquire its admirable educational system by popular demand—nor does England owe such institutions as the College of Chemistry, the School of Mines, the Royal College of Science and the national art schools and schools of design to political agitators. Still less did the professional class of educationists help in either case—on the contrary, they bitterly and fiercely opposed these new developments. They are due in Germany to the Kings of Prussia; in England to the late Prince Albert. The only chance, it seems to me, which this country has for a change in the methods and aims of its education, and of its administration, which largely depends on the education of its administrators, is in the absolute conviction on the part of a great statesman, or, I say it with the deepest respect, of the King himself, that such change is of vital importance and is the one step necessary for the future welfare of the British nation. The crowd cannot guide itself, cannot help itself in its blind impotence. Here is the opportunity, the duty, of the greatest in the land.

Prof. Pearson's address was delivered at a time when the nation was suffering from the stress of war in South Africa. He has endeavoured to avail himself of the temporary awakening of the English people from their self-satisfied toleration of incompetence in order to press home the national need for the better training of its brains and the utilisation of the brains when trained. That is well-timed and legitimate. But when Prof. Pearson goes on to assert that the struggle between great civilised nations for territory, for trade-routes and for supremacy in manufactures—by warfare or by starvation—is the necessary condition, the moving power of human progress, he goes, I think, altogether beyond the conclusions which are warranted by our knowledge and beyond the indications which strictly follow from the application to this problem of the conclusions of biological science. He says:

"This dependence of progress on the survival of the fitter race, terribly black as it may seem to some of you, gives the struggle for existence its redeeming features; it is the fiery crucible out of which comes the finer metal. You may hope for a time when the sword shall be turned into the plough-share. . . . But, believe me, when that day comes mankind will no longer progress; . . . man will stagnate. . . ."

I do not hesitate to state, with a full sense of the gravity of the issue, that Prof. Pearson has no warrant in our present knowledge of the laws of development of animal societies or of human communities for this statement. This is certainly not a conclusion which can be for a moment pressed on popular acceptance as coming from the standpoint of science. It seems rather to originate in a hasty attempt to generalise from certain preliminary results of biology to conclusions in regard to an enormous unexplored field of human phenomena. I admit that the struggle between communities of human beings has resulted in the suppression of the more violent instincts of the individual and has led to the development, as an element of communal strength, of that quality which we know as human sympathy, to the elaboration of social instincts, of civic virtues, of pity and of principles of conduct. The list is Prof. Pearson's. But it has yet to be shown that there is any strict analogy between the struggle for existence of the countless individuals in each generation of a non-social species and the competition of great nations or great races of mankind. In the former case an immense number of variations is continually presented, and a remorseless destruction of all but the selected few. In the latter there is no great variation among the competitors on a given area and there is no destruction and consequent removal from reproductive perpetuation of the less successful community. The highly specialised communities of social insects might perhaps be fittingly dealt with in such prophecies as Prof. Pearson applies to mankind. It is, on the other hand, necessary to remember that the communities of human beings are far less individualised than are those of the insects referred to. One ant colony may utterly destroy another; one community of bees or wasps may exterminate its neighbour. But in the struggles of human communities in these later days the conquerors absorb and do not annihilate their competitors in those cases where there is any similarity of race. In these later days the struggle is for the supremacy of a special form of political organisation, and not for the extinction or the survival of a breed. Moreover, the new and strangely significant factor of oral and written tradition is operative in civilised communities, so that a race, though dead or merged in other races, yet continues to speak in the works of its greatest men.

Further, it seems to be beyond doubt that that progress of humanity, which consists in the production of those splendid individuals who have blessed their race by great discoveries in science and by great creations in art, is not in any way promoted, but is, on the contrary, hindered by the diversion of the energies and resources of the community to warfare and aggressive struggle. Just as the race of the jungle-cock cannot develop a nine-foot tail-feather when fighting its fellows as a struggling breed, but when removed from the restricting influences of natural selection bursts out in the Japanese poultry yards into such magnificent "sports," so humanity can only develop that "sport" which we call genius when it has reached social conditions of security and freedom from the demands of international warfare. Those nine-foot sports of the human brain which we know as Shakespeare, Newton, Raphael and Mozart were most certainly not traceable to the struggles of their native communities with other communities for territory, trade-routes or commerce. Rather, it would seem, were they and others like them only possible as the outcome of conditions when defence and offence were occupying but little of the strength and thought of their own and neighbouring nationalities. And there is this to be noticed by those who, like Prof. Pearson, would apply particular conclusions of biological science, without discrimination or reserve, to human society—viz. that whereas the corporeal "sports" of animal stock can only affect subsequent generations by the physical process of reproduction, the sports of the human mind—and, indeed, all individual minds and characters which rise above the herd—have, in consequence of the perfection of our records, an enduring influence upon vast numbers in the later generations, not only of one, but of all civilised communities.

I, for one, do not despair of humanity; I see no reason to suppose that what might be called "progress"

is impossible in the absence of bloodshed and international hostility. There is much ambiguity in the word "progress." A movement or change in human society which by some thinkers would be called "progress," would by others be called "retrogression," whilst others would deny the very existence of a change and see stagnation in place of either. Prof. Pearson, like other prophets of things to come, uses terms of conveniently vague significance. He should tell us more clearly what he means by "human progress" before he asks us to accept it as the end which justifies human warfare.

E. RAY LANKESTER.

Prof. Karl Pearson has for some years devoted his mathematical knowledge to a more exact co-ordination of observations on heredity. It cannot be said that in this address he uses any results of his study which were previously unknown to us through the observations of breeders of animals and the facts recorded by Mr. Galton. Prof. Pearson affirms that the "earlier interpreters of evolution" obscured it, and much of his address is devoted to pointing out that the association of individuals in a tribe made the development of human love and sympathy a necessity.

Now surely Huxley was the very earliest interpreter of evolution, and there was no part of the doctrine to which he devoted more attention than this very subject—evolution and ethics. But it is good that facts, however well known they may be to readers of NATURE, should be set forth strongly in an address which has a chance of coming before other readers.

The essential part of the address shows that a nation must be untiring and unresting in its efforts to increase its "brain" power; to increase its proportion of people of better brains and physique, if it is to hold its own against other nations. It is certain that we readers of NATURE are all in agreement with the author, and we are all in sympathy with him in his effort to rouse our sleeping nation, and to make it feel that the struggle for existence is not merely among neighbouring individuals, nor tribes, nor cities, nor counties, but among nations. We may go further, and say that every man of sense in the kingdom is fully alive to the fact that this struggle for existence is going on, and we only differ as to the best method of increasing the strength of our own people. There are many other things to be thought of, many things which Prof. Pearson's mere Aryan science cannot take into account. A nation, like a man or a field, needs occasional intervals of lying fallow. After national existence is secure, there is something important in the development of international friendship and affection. As care for the tribe preceded care for the nation, so care for the nation may only precede care for a federation of the nations. The struggle between some nations in Europe may be so bitter as to make them unfit for combination against a fitter Sclavonic and Asiatic federation. But these considerations must give place when our own nation is in such great danger as it is at the present time. Huxley and many others spoke of this danger and pointed out the remedy long ago, when the danger was remote; now it is coming swiftly upon us, and we can only repeat the same warnings and give the same advice in shriller and more vehement tones.

To show how we are continually saying the same things in regard to education, I would direct attention to "The Education of our Industrial Classes," an address delivered in 1883 by Sir Norman Lockyer, (Macmillan and Co.). At p. 16 I find the following words:—

"It is half a century since the Germans found out the importance of the new studies from a national point of view. We are now finding it out for ourselves, and finding it out not a moment too soon; and I need hardly tell you that the transformation which is going on is acknowledged to be one of the highest national importance. It is no longer an abstract question of a method of education; it is a question of the life or death of many of our national industries, for, in the struggle for existence, how can a man who wins his bread by the application of natural laws to some branch of industry, if he be ignorant of those laws, compete with the man who is acquainted with them? If for man we read nation, you see our present position."

The author, although he fears that our economic and social conditions are hardly ripe for such a movement, seems to favour Mr. Galton's notion that there ought to be social action towards an endeavour to prevent the inferior stock of people among us from breeding at will; making the all-important question of parentage a matter not of family, but of national importance. He points out that France is becoming a land of Bretons because the Bretons alone have large families, and that the feckless, improvident and brainless people in England among the very poor and the very rich have the largest families, whereas the provident people

"have been marrying late, have been having small families, have been increasing their individual comfort, and all this is at the expense of the nation's future."

This is why we are defeated commercially by Germans. He points out that a mere multiplication of centres of technical instruction will do no good against the American and German, as it is only where brains already exist that training is of use. He points out that nurture and education may immensely aid the social machine, but they must be repeated generation by generation; they will not in themselves reduce the tendency to the production of bad stock. He believes the Kaffir and Negro and Red Indian so low that they must be destroyed; that for a good stock of people to live alongside a bad stock, or to keep them as slaves, or to intermarry with them, is only to prepare a cataclysmal solution for the future.

It would, we think, be easy to prove, from the condition of mongrel races and from the history of the fall and rise of nations, that these statements are not the teachings of science; but let us suppose for a moment that he is right about England. During the French revolution a speaker declared, day after day, with vehemence, that the simple remedy for all French evils was "to kill all the scoundrels and traitors." Prof Pearson's remedy for all evils is to diminish the proportion of bad stock; but who are the people of England of bad stock? He himself confesses that they may be among the very rich as well as among the very poor; we are inclined to think that he would find much the same proportion among the middle class people, or Philistines, who "have been increasing their individual comfort."

He is specially wrong when he says that education will not improve the stock. On the contrary, we think that

it is by education alone, the education of the whole people, that such improvement can take place. Educated young people will so select partners that the stock will rapidly improve, and the improved stock will ask for better education still. What governor, however scientific, can so direct the choice of millions of different people as they themselves can if properly educated? for each case needs not only special scientific study, but something very much outside what we usually call science.

Whatever the stock, the author thinks—as we do—that it is only by education in scientific schools that, in a particular generation, a particular nation is made able to compete with other nations either in the arts of war or of peace.

Unfortunately, he leaves us in great doubt as to what he means by a scientific school. Over and over again he attacks the technical schools, which in this country are getting to be so numerous and which are improving in their methods every year. We feel sure that he cannot have studied this matter. He seems to think that the numerous great technical schools merely teach trade tricks and trade skill and trade formulæ. There are technical schools attached to all the great colleges and universities. There are the technical colleges of the City and Guilds of London Institute. He will find that in all these, students are instructed through experiment, through their own observation and through mathematical deduction, in those scientific principles which underlie their future profession. The wail of the teacher in such classes is always that his pupils have been so badly taught at school that they cannot observe, they cannot think for themselves, they cannot reason, they cannot even express themselves on paper; what they have learnt as mathematics is in no sense a part of their mental machinery and cannot be used in reasoning. The author says that for sixteen years he has himself been helping to train engineers, and he describes how he endeavours to make his students observe and think for themselves. And does not every teacher of mathematics or applied mathematics to engineers at all the other technical schools in the country try to do the same? Has he any kind of proof that they do not? It is quite true that at some colleges the teacher may have been badly selected, selected merely because he took a good place in the mathematical tripos, a man with no liking or aptitude for teaching; but we beg to assure Prof. Pearson that such men are the exception, and not the rule, at the technical schools with which we are acquainted. Unfortunately, at all these colleges the teachers find many, or indeed most, of their pupils unprepared for the higher, more complex work which some years hence will, we hope, really be taken up by all students in these schools and colleges. And so it is that many engineering students, like Prof. Pearson's pupils, after they leave college "adapt themselves to an environment more or less different from that of the existing profession." If these young engineers had been brought up from early youth to observe and think for themselves, there would be no need to teach them the most elementary principles of "scouting" at the ages of eighteen to twenty, when, in truth, they ought to have already entered the practice of their profession. True it is that for these ignorant young men the very simplest scientific apparatus may serve; but there are some students who have already been trained to scout, who come prepared to be taught under our contemptible "brand-new system of technical instruction," and it is for them that we have our ridiculously unnecessary "physicist with palatial laboratory and elaborate and costly implements" and that there exists "the biologist with his 80*l.* microscopes and specimens drawn from the four quarters of the globe." Surely Prof. Pearson must see that the education which we all know to be so necessary for the development of the faculties ought to be begun in early youth, that there is at present no genuine education in English public schools, and that without physical science such an education cannot be given.

It is not alone the teacher in a technical college who complains of the absence of education in the public schools. Whether they apply themselves to commerce or manufactures, whether they enter one profession or another, whether they try to become diplomatists or statesmen, our boys are found to have had no education. In days when all Europe was at war and we were safe in our island, our grandfathers gathered to themselves all the good things of the world, and now we are living on their legacy. And we are blind to the fact that the lean and hungry nations, covetous, cautious and disciplined, are almost quarrelling already over us, their prey. If there are enough honest and thinking men in England this day they will speak to England loud enough to stir her out of her apathy; or if not, and if England cannot be so stirred, let her descend to her natural position; let the stranger come in and divide her property; even the property of those men who are selfishly silent. Our cry is for education and only that; true education for everybody, from the highest to the lowest, is a national necessity more important than any weapon of war or any political machinery for the repression of bad stock, because education will give us all these things and much more.

JOHN PERRY.

THE DISCOVERER OF LAKE NGAMI.

William Cotton Oswell, Hunter and Explorer. By his son, W. E. Oswell. Two volumes. (London: W. Heinemann, 1900.)

SO far as the general public are concerned, the interest in the career of the late Mr. Oswell may be said to begin and end with the period (from 1844 to 1852) during which he made his five expeditions to Africa, at a time when by far the greater portion of that continent was still a *terra incognita*. But this period of the life of the great explorer and hunter occupies only a comparatively small portion of the two volumes before us, the bulk of which is taken up by an account of the parentage and early years of Oswell, and with letters to his family and friends. However interesting these may be to his immediate relations, we venture to submit that they appeal but slightly to the general public; and, in our opinion, the author would have been much better advised had he condensed his narrative into the space of a single volume of the bulk of one of the two under notice.

Apart from this, the author has discharged a task of considerable difficulty and delicacy (for it is never an easy matter for a son to write the biography of his father) in a highly creditable and satisfactory manner.

Until the appearance in 1894 of his chapters on hunting in Africa (written, after much persuasion, at the instance of Sir Samuel Baker) in the "Big Game" volume of the *Badminton Library*, the world knew practically nothing of Oswell's South African explorations and experiences, except what can be gleaned from Livingstone's "Missionary Travels."[1] The information given in the present volumes, though far less full than could be desired, tells the story of his adventures in considerably more detail than is the case in the articles referred to, and its publication is therefore a distinct gain to our knowledge of the early days of African exploration.

Oswell's persistent refusal to take any share in the honours attaching to the discovery of Lake Ngami, and his self-abnegation in permitting nothing from his own pen to forestall the appearance of Livingstone's volume, are now matters of history, and are alluded to in some detail in the introduction by Mr. Francis Galton to the work under review. But there can be no hesitation in admitting that as Oswell originated the idea and fitted out the expedition at his own cost, the honour and glory of the discovery should by rights have been his and his alone. Indeed, this is practically admitted by Livingstone himself. And here it may be said that we are not for a moment casting the slightest reflection on the great missionary explorer. The account of the discovery of Lake Ngami had to be written and published, and as Oswell refused to undertake the task it was the bounden duty of Livingstone to do so. The destruction of his own journals by Oswell, in case they should be published before the appearance of Livingstone's work, is, however, a matter which must always remain one for serious regret.

In this connection, it may not be out of place to mention that there is a discrepancy between the accounts of Livingstone and Oswell as to the precise date on which the great lake was discovered. Livingstone[2] states that "it was on the 1st of August [1849] that we reached the north-east [or lower] end of the Ngami." Oswell, on the other hand, as quoted on p. 201 of the first volume of the work under review, says that

"We started on the 16th of July, and after twelve days' march arrived at the half tribe of the Bamanguato, who call themselves Batouani. We outspanned nearly abreast of the town at the lower end of the Lake."

This would make the date of its discovery July 28. It is, of course, a matter of slight moment, but it would be interesting to find whether original manuscripts throw any light on the reason of the discrepancy.

It is to the African adventures of Oswell that our remaining space will be restricted. Several of his encounters with, and escapes from, wild animals mentioned in the present work have been already narrated in the *Badminton Library*, from which the illustrations have been reproduced. These latter were drawn by Joseph Wolf under the personal supervision of Oswell himself, and may be taken to be as truthful representations of the actual scenes as could be obtained without the aid of photography. It must, however, be confessed that, either from the wearing of the blocks or from the fault of the printer, the reproductions are by no means equal to the original plates. This inequality will be manifest if the plate facing p. 16 of vol. ii. of the work before us be compared with its prototype facing p. 128 of vol. i. on "Big Game Shooting" in the *Badminton Library*.

Like Cornwallis Harris and his own companion, Frank Vardon, Oswell was in the service of the Hon. East India Company, although in a civilian instead of a military capacity, and it was ill-health in India that led him to recruit his energies in the Cape. Both on his first expedition with Murray, and on his second with Vardon in 1844 and 1845, Oswell, to quote his own words,

"penetrated far beyond the utmost limits of previous geographical knowledge, exploring, hunting, revelling with them in shooting such as no men ever had before or will ever have again, the first Europeans and the first guns among the myriads of animals."

His acquaintance with Livingstone commenced in 1845 and continued till the death of the latter. On his return to Africa in 1848 from a short sojourn in India, the great expedition to Lake Ngami was organised and brought to a successful conclusion, his companions being Livingstone and Murray. The triumph of the march was the crossing of the Kalahari desert, for when the Zouga—the effluent of Ngami—was reached, the difficulties were over, and patience and perseverance were alone necessary. The fourth expedition, undertaken alone, was mainly occupied in shooting on previous routes; but in the fifth, which was undertaken with Livingstone, the course of the Zambesi and its tributaries was mapped for the first time, and the myth that the former discharged at Delagoa Bay disposed of for ever.

Although, unfortunately, neither of the quartet was a naturalist in the true sense of the term, their expeditions largely extended our knowledge of South African animals. During the third expedition, those beautiful antelopes the lichi (*Cobus leche*) and puku (*C. vardoni*) were discovered; and it seems that Livingstone or Oswell were really the discoverers of the nakong, or situtunga antelope, or, at all events, of the Chobi representative of the same, although the animal was named from specimens brought home at a much later date by Speke. A rhinoceros was also named after Oswell by Gray, being regarded as distinct from *Rhinoceros simus* on account of the forward direction of the front horn, which is always worn at the tip by being pushed along the ground. Later writers, and even Oswell himself, have, however, denied the distinctness of this form. But Oswell's notes tell us that the quebaaba—as this animal is always called by the natives—was never found below the southern tropic. If it had been the sole white rhinoceros north of the tropic, it would have undoubtedly been entitled to rank as a local race. And even as matters now stand its true affinities are worth the attention of naturalists.

Another piece of information afforded us by Oswell's notes is the fact that elephants from different localities in South Africa present certain points of difference. He says, for instance (vol. i. p. 205), that on the Zouga "the elephants are a distinct variety from the Limpopo ones; much lower and smaller in body (10 feet is a large bull), but with capital tusks." This also is worthy the best attention of zoologists, although it is to be feared that it is now late to differentiate local races of the species, if such

[1] In the popular edition of that work, published in 1861, Oswell's name is not even mentioned in the index, although it occurs on certain of the plates.

[2] *Op. cit.* p. 46.

really existed.[1] It is to be regretted that before making the statement (vol. i. p. 219) that a pair of gemsbok horns obtained by Oswell, which measure 44 inches, are the longest but one on record the author did not consult some recent works on horn-measurements. Had he done so, he would have found that these dimensions are exceeded by five examples, the "record" length being $47\frac{1}{2}$ inches.

Of the profusion of great game in Central South Africa in Oswell's time, and of its subsequent extermination, the story has been told so often that its recapitulation here would be superfluous. Whether Oswell and his successors were altogether free from blame in regard to indiscriminate slaughter is a question which it is not our province to answer on this occasion. He himself wrote, somewhat pathetically, in after years as follows: "I am sorry now for all the fine old beasts I have killed, but I was young then, there was excitement in the work; I had large numbers of men to feed; and if these are not sound excuses for slaughter, the regret is lessened by the knowledge that every animal I shot, save three elephants, was eaten by man, and so put to a good use."

That Oswell was a gallant and noble-hearted gentleman, as well as a true sportsman, will, we think, be the verdict of all who read a very attractive, albeit in certain respects a somewhat saddening, book. R. L.

[1] Since the review was written Dr. Matschie, of Berlin, has proposed to split up the African elephant into several so-called species.

THE WORKS OF C. F. GAUSS.

Carl Friedrich Gauss Werke. Achter Band. Pp. 458. (Leipzig: Teubner, 1900.)

THE contents of this volume consist mainly of reviews, correspondence and a series of posthumous fragments relating to various branches of pure mathematics. It not unfrequently happens that a mathematician's unfinished essays, only brought to light after his death, are even more stimulating than the finished works which he published during his life. This is especially true of Gauss. As he says himself in one of his letters, he aimed at the utmost perfection of form; he worked, as it were, in marble, and did not give his masterpieces to the world until they had been elaborated to the highest degree of symmetry and polish. The result is that, when we study the productions of his genius, we feel a kind of awed admiration which is not entirely free from a sense of chill; his stately synthesis compels our assent, but does not always attract our sympathy, and rarely suggests the idea of even the humblest emulation. Gauss's own countryman, Jacobi, in his lectures on the theory of numbers, refers with a touch of bitterness to the frozen austerity of Gauss's demonstrations.

Much, then, as we may deplore the fact that Gauss's official duties, as well as his fastidious habit of composition, prevented him from working out the details of so many of his great ideas, there is a certain consolation in being able to see, in the notes which have been preserved, some traces of the inception of his far-reaching discoveries. There is no need now to emphasise the extraordinary way in which he anticipated many of the most important results obtained by other men. We can understand the suspicion and incredulity with which his claims were regarded by some of his contemporaries; but no one can doubt the extent and independence of his researches in the theories of elliptic functions, of modular functions, and of non-Euclidean geometry, not to mention other things. It must have been very trying to him to see so much of his work forestalled, so far as priority of publication was concerned; and on the whole it may be said that he betrayed less disappointment than might have been expected. It is true that in this volume there are letters of a rather controversial kind, in which he emphatically claims priority in the discovery of the method of least squares; but he refers appreciatively to Legendre's work on cometary orbits, adding pathetically,

"Es scheint mein Schicksal zu sein, fast in allen meinen theoretischen Arbeiten mit Legendre zu concurriren."

And in writing to Bolyai (a friend, it is true) about the non-Euclidean geometry, after saying that his many engagements prevent him from thinking of the subject for the present, he continues:

"Es soll mich herzlich herzlich freuen, wenn Du mir zuvorkommst, und es Dir gelingt alle Hindernisse zu übersteigen. Ich würde dann mit der innigsten Freude alles thun, um Dein Verdienst gelten zu machen und ins Licht zu stellen, so viel in meinen Kräften steht."

The letters and notes on the foundations of geometry form one of the most interesting sections of this volume. It is clear that before the end of 1799 Gauss had critically examined the theory of parallels, and begun to doubt its necessary truth: he says that he could prove the whole of geometry if it could be shown that a rectilinear triangle is possible, the area of which exceeds that of any given surface; but that, far from assuming this as an axiom, he thinks it may be possible that, however great the sides of the triangle are taken, the area is less than a certain fixed quantity. He returned to the subject from time to time during many years. It appears from a letter of Gauss to Gerling, dated March 16, 1819, that he had then obtained some of the principal results in that species of geometry in which the sum of the angles of a rectilinear triangle is less than two right angles, for he gives the formula

$$\text{“Limes areæ trianguli plani} = \frac{\pi CC}{\{\log \text{hyp}\,(1+\sqrt{2})\}^2}\text{,”}$$

where C is a certain constant determined by the space under consideration. Gauss refers again to this constant in a letter of November 8, 1824, and speaks of it as "a definite (an sich bestimmte) linear magnitude existing in space, although unknown to us." This is not very clear, and the context does not enlighten us, in spite of its criticism of the philosophers. The fact is that Gauss nowhere (apparently) in these fragments expresses himself with perfect clearness about this constant. He had arrived at the notion of an upper limit to the area of a triangle; but he never suggests the possibility of an upper limit to the distance between two points, and, in fact, assumes that there is none. Moreover, he dismisses without sufficient consideration the question of how such a thing as an *absolute* distance is conceivable, and ignores the fundamental difficulties which beset the application of number to measurement. It is very remarkable that so

consummate an analyst failed to realise completely that no strict mathematical theory of the metrical properties of space is possible until the elements of space have been brought into correspondence with a definite arithmetical manifold. One such manifold is the field of analytical points (x, y, z) used in ordinary algebraic geometry. Its metrical properties admit of analytical definition, and are capable of exact determination. They apply to "real" space in so far as they belong to a system suggested by intuitions of sense, and therefore necessarily associated with intuitional experience. But no intuition can give a complete theory of space; and the question whether "real" space is Euclidean or non-Euclidean is one that, from the nature of the case, cannot possibly be answered, and it may even be doubted whether it has any meaning at all.

Some of Gauss's remarks on the metaphysics of space are extremely interesting, even though they may not, to every one, carry complete conviction. Thus, he says, "Der Unterschied zwischen Rechts und Links lässt sich nicht definiren, sondern nur vorzeigen," and proceeds to assert that the distinction can only be indicated by one intellect to another by means of a material object. He then says, in conclusion, that he finds in this a striking refutation of Kant's notion that space is *merely* the form of our outer intuition ("Der Raum sei *bloss* die Form unserer aüssern Anschauung"). It is difficult not to see in this both vagueness of reasoning and a misapprehension of Kant. If "right" and "left" are terms used to indicate a distinction apprehended by sense, Gauss's statement is so obvious as not to be worth making; but when they are applied to relations of position in a mathematical space they *do* admit of definition, not absolutely, but as correlative terms. And even from the first point of view there is nothing in the fact to which Gauss calls attention which is inconsistent with Kant's assertion that space is a form, or scheme, in terms of which we interpret (or into which we fit) certain related groups of our sensuous impressions. This pre-Kantian attitude of Gauss is illustrated by other allusions to the "reality" of space. But it should be noticed that he expressly says that since a geometry of more than three dimensions can be considered *in abstracto* without contradiction, even though we have no corresponding intuitions, it is possible that such a geometry is accessible to beings of a higher order. He hopes, too, that in another life he may be able to see more into the essential nature of geometry.

The rest of the volume must be dismissed with a very few words. From the notes on elliptic transcendents it is clear that Gauss not only inverted the general elliptic integral, but expressed the result as the quotient of two integral functions: that his work on the arithmetico-geometric mean led him to the group of linear transformations of the period which leaves the modulus κ^2 unaltered; and that he represented this group geometrically, actually drawing a figure for the fundamental triangle and a few of its derivatives. A letter to Bessel, dated December 18, 1811, shows him to be in possession of the principles of complex integration. There is a considerable series of notes on the analytical theory of surfaces, most of which was incorporated in the famous memoir; applications of complex numbers to geometry, and especially to transformations of space, on which there are two short but very suggestive notes; a fragment on knots, with a very convenient notation, and a complete table of different knots with less than six crossings; and finally, there are notes on the barycentric calculus, with a formula $B - C = ai$, curiously like Grassmann's notation in the *Ausdehnungslehre*. These seem to be the most important items; several, which are of less interest, have not been mentioned.

CHINESE AFFAIRS.

China: Her History, Diplomacy and Commerce from the Earliest Times to the Present Day. By E. H. Parker. Pp. xx + 332. (London: Murray, 1901.) 8*s.* net.

CHINA is an inexhaustible subject, and though we have lately had books in abundance on modern affairs and the present crisis, there is still room for such a work as Mr. Parker's "China." It aims at a great deal more than an account of current politics, and supplies a whole army of facts and statistics on the history, trade and government of the Empire. The chapters on the history will be found valuable. They are full of information, and will well bear a careful study. But the later portion of the work, beginning with the introduction of foreign trade, will probably be found the more generally interesting part. Mr. Parker opens this section with the life and trade at Canton, where British merchants were "cabined, cribbed, confined" in what was known as the "Factory."

"The merchants," he tells us, "passed a confined, ceremonious and reserved existence, entirely in the hands of their *Fiadors* and *Compradores*, on the one hand, and of the Chinese Cohong on the other. No wives were allowed, and even burials had to take place at Whanpoa, twelve miles down the river. It was only in 1828 that the British superintendent first succeeded in getting his wife up. British trade was, of course, the largest of all; lead (for packing tea) and woollens were the chief imports (no specie, no cotton fabrics) from England, opium from India, and the usual 'Straits' produce picked up from the Dutch colonies visited by our ships *en route*. Tea and silk were the main exports then as now. The British tea consumption in 1795 was 14,000,000 lbs. a year, more than one-half of which total was smuggled by foreign ships from Canton operating in the English Channel."

Since those days a complete change has come over our trade. India and Ceylon have competed so successfully with China in the production of tea that, whereas in 1880 2,100,000 cwt. of the leaf were exported from China, only 1,631,000 cwt. left the country in 1899. But while this export has thus diminished, certain new imports have been greedily accepted by the people. Kerosene oil is one of these. Before 1880 little was heard of it in China, while in 1890 more than a hundred million gallons were imported. On this and other articles of trade, Mr. Parker writes:—

"Mules may be seen by the thousand in distant Bhamo carrying kerosene oil through the passes into Yunnan; peasants may be met every evening in arcadian Hainan carrying home a neat pound bag of beautiful white flour, together with a farthing's worth of periwinkles their ancestors have always brought home of an evening as a relish for their rice. An immense trade is done in old English horse-shoes, which are considered the best iron in the world for making small

household articles, such as brackets, hooks and bolts. I have seen steamer after steamer disgorge this paying and useful ballast at Shanghai. Another revelation is the commercial capacity of the Bombay yarn . . . of which Japan also, who now sends her own yarn and piece goods to China, for some years imported annually one million sterling's worth. The trade in arms and ammunition has enormously expanded, chiefly in the hands of the Germans, who are now receiving an unpleasant reminder that this particular activity is apt to cut both ways."

Mr. Parker speaks, and speaks justly, of the honesty of the Chinese merchants, and has something to say for the honesty of the people generally. But, like the sale of arms, his argument on this subject cuts both ways. He assures us that he never lost anything of value while in China. This may perhaps be accounted for by the facts that he always kept his safe locked, and that he possessed no jewellery but that which he habitually wore on his person He incidentally mentions also that on one occasion he asked his "boy" how it was that so many of his forks had a stain. To which his "boy" replied that it had been done by

"various coolies or underservants, each of whom in succession invariably tested the electro on his own account, merely as a businesslike act."

On another occasion, when he wished to lock up the same electro box, he (the "boy") said :—

"Not at all ; if you lock it up, some one will mistake the contents for silver, and carry the whole box away or break it open ; whereas, if you leave it open, each thief will be able to ascertain for himself that it is not worth stealing."

The only time, he tells us, that he suffered any depredation was when a thief, at an inn, carried him and his bed to a convenient spot, and extracted a valuable fur coat from beneath him, without disturbing his slumbers. Altogether his chapter on the national characteristics of Chinamen is amusing reading, and all the more so since, quite unconsciously, he assumes throughout his remarks on the subject the attitude of the "Devil's Advocate."

ANTHROPOLOGY IN ITS SCIENTIFIC AND EDUCATIONAL ASPECTS.

Anthropologie als Wissenschaft und Lehrfach. By Dr. Rudolf Martin. Pp. 30. (Jena : Fischer, 1901.)

THE inaugural lecture delivered by Dr. Martin on the occasion of his appointment to the newly founded chair of anthropology in the University of Zürich may be described as a survey of the present state of anthropological science, together with some most opportune suggestions regarding anthropology as an instrument of education. After a few remarks on the gradual process by which anthropology has acquired a position of independence among other sciences, the author turns to the range of subjects now studied under the title of anthropology, and, in the first place, draws a strong line of distinction between the physical and the psychical aspects of that science. With the former are placed the sciences of physiology and pathology, while the latter division is taken as applying, in the first instance, not so much to the psychology of the individual as to that of various groups of humanity judged by their culture and social status. With the latter, the psychical, division there must be ranked the studies of archæology and of prehistoric anthropology. The distinction of the classifications of mankind based on the two great divisions of anthropology respectively is strongly insisted upon, and the methods of anthropologists call for some words of warning in this connection. The aims laid before future workers by Dr. Martin are, so far as regards the methods to be employed, a rational, systematic and uniform use of numerical data ; at the same time, we are reminded of instances that have occurred in past years of misapprehension of the true significance of the results of such methods, and are warned of the necessity of exercising the greatest care in judging similar results in the future. With particular reference to the classification of human races on physical grounds, the necessity of employing, not a single character, but a combination of features as the criterion of differences is dwelt upon at some length, and the urgent need for immediate action in the case of primitive races now fast dying out is also clearly expressed. The first part of the essay concludes with suggestions as to the lines of investigations to be pursued in the case of mixed races, and with a firm insistence on the importance of an intimate knowledge of the anatomy of the mammals of the order Primates, to those who work at the physical side of anthropology.

Dr. Martin then proceeds to discuss the place of anthropology in University teaching, and while considering that it must be studied in connection with what we may call unapplied sciences (his precise expression is "the mathematical and scientific section of the Philosophical Faculty," for which we have no exact equivalent in English universities), he is well aware of the advantages conferred upon those working at the physical side of anthropology by a knowledge of the elements of medical science, and, above all, of human anatomy as studied in the dissecting room. A place is therefore claimed for anthropology in the education of every professional man, but more particularly for those who teach in the higher schools, for medical men, and last, but not least, for those who hold administrative or other posts in colonial possessions. The application of anthropological methods to the identification of criminals is also mentioned. Finally, there are pointed out the claims of anthropology to figure as part of a liberal education, independently of any professional application of its results, and we are reminded of the deep significance of the attempt to realise, in its fullest sense "man's place in nature."

The foregoing notes will, it is hoped, convey an idea of the scope and purport of Dr. Martin's lecture. It may be mentioned that Dr. Martin, besides being the author of important contributions to anthropology both in the laboratory and in the field, is deeply versed in philosophical studies. His opinions on the methods and aims of anthropology will be received with all the greater consideration by those who are interested in the future of that science. In a single lecture it was manifestly impossible to do more than indicate the chief points and we think that Dr. Martin has not overlooked any of great importance. From this point of view we think that the essay constitutes a valuable survey of the subject and that it appears very opportunely at the commencement of the twentieth century. W. L. H. D.
